PAPERS COMMUNICATED TO THE CHEMICAL SOCIETY.

	PAGE
CCX.—The Active Constituents of the Indian Solanaceous Plants <i>Datura Stramonium</i> , <i>D. fastuosa</i> , and <i>D. Metel</i> . By ALBERT EDWARD ANDREWS	1871
CCXI.—A New Stereoisomeride of Cyanodihydrocarvone. By ARTHUR LAPWORTH and VICTOR STEELE	1877
CCXII.—Some Properties of Phenyl isoPropyl Ketone. By ARTHUR LAPWORTH and VICTOR STEELE	1882
CCXIII.—Contributions to the Chemistry of the Terpenes. Part X. The Action of Chromyl Chloride, Nitrous Acid, and Nitric Acid on Bornylene. By GEORGE GERALD HENDERSON and ISIDOR MORRIS HEILBRON	1887
CCXIV.—The Constitution of Camphene. By GEORGE GERALD HENDERSON and ISIDOR MORRIS HEILBRON	1901
CCXV.—The Action of Chlorine on Alkalis and of Carbon Dioxide on Bleaching Powder. By ROBERT LLEWELLYN TAYLOR	1906
CCXVI.—Experiments on the Walden Inversion. Part VII. Action of Phosphorus Pentachloride and of Thionyl Chloride on Optically Active Hydroxy-acids and Esters. By ALEX. MCKENZIE and FRED BARROW	1910
CCXVII.—The Relation between Residual Affinity and Chemical Constitution. Part II. Certain Compounds of Nitrogen. By HANS THACHER CLARKE (1851 Exhibition Scholar)	1927
CCXVIII.—The Temperature-coefficient of the Electrical Conductivity of Hydrogen Chloride in Alcoholic Solution. By JAMES RIDDICK PARTINGTON	1937
CCXIX.—The Absorption Spectra of the Nitration Products of Dimethyl- <i>p</i> -toluidine. By GILBERT T. MORGAN and ARTHUR CLAYTON	1941
CCXX.—Decomposition of Hydrazides and Hydrazones by Heat. By FREDERICK DANIEL CHATTAWAY, CHARLES LINAEUS CUMMING, and BERNARD HOWELL WILSDON	1950
CCXXI.—The Absorption Spectra of Triketohydrindene Hydrate and Certain Derivatives. By JOHN EDWARD PURVIS	1953

	PAGE
CCXXII.—The Alkaline Condensations of Nitrohydrazo-compounds. Part I. By ARTHUR GEORGE GREEN and ERNEST ARTHUR BEARDER	196
CCXXIII.—Trimercuridiethylammonium Nitrite. By PRAPULLA CHANDRA RAY and JITENDRA NATH RAKSHIT	197
CCXXIV.—Studies of Ammonium Solutions. Part I. An Ammonium Electrode. By ROLAND EDGAR SLADE	197
CCXXV.—Studies in the Camphane Series. Part XXX. Constitution of Pernitrosocamphor (Camphenylnitroamine). By MARTIN ONSLOW FORSTER, JOHN ROBERT TROTTER, and JACOB WEINTROUBER	198
CCXXVI.—The Constituents of the Seeds of <i>Casimiroa edulis</i> . By FREDERICK BELDING POWER and THOMAS CALLAN	199
CCXXVII.—Komppa's Synthesis of Camphoric Acid. By GUSTAVE LOUIS BLANC and JOCKLYN FIELD THORPE	201
CCXXVIII.—The Lower Limit of Inflammation of Mixtures of the Paraffin Hydrocarbons with Air. By MAURICE JOHN BURGESS and RICHARD VERNON WHEELER	201
CCXXIX.— β -2-Methoxynaphthylpropionic Acid and Methoxypinnaphth-hydrindone. By GEORGE BARGER and WALTER WILLIAM STABLING	203
CCXXX.—Syntheses with Phenol Derivatives Containing a Mobile Nitro-group. Part V. Quinoneimides, Asymmetric Quaternary Ammonium Compounds, and Asymmetric Carbinols (<i>continued</i>). By RAPHAEL MELDOLA and HAROLD KUNTZEN	203
CCXXXI.—The Synthesis of Derivatives of Thioxanthone. Part IV. Synthesis from Aromatic Sulphinic Acids. By HAROLD CHRISTOPHER and SAMUEL SMILES	204
CCXXXII.—Some Derivatives of 4(or 5)-Methylglyoxaline. By ARTHUR JAMES EWINS	205
CCXXXIII.—The Triazo-group. Part XIX. Nitrosoazides of Dipentene, <i>d</i> -Limonene, and <i>l</i> -Limonene. By MARTIN ONSLOW FORSTER and FREDERIK MARINUS VAN GELDEREN	205
CCXXXIV.—Preparation of the Betaine of Tryptophan and its Identity with the Alkaloid Hypaphorine. By PIETER VAN ROMBURGH and GEORGE BARGER	206
CCXXXV.—Dihydroxydihydrindamine and its Resolution into Optically Active Components. By WILLIAM JACKSON POPE and JOHN READ	207
CCXXXVI.—Studies in Phototropy and Thermotropy. Part II. Naphthylideneamines. By ALFRED SENIER and ROSALIND CLARKE	208

CONTENTS.

iii

	PAGE
XXXXVII.—Isomeric Acetaldehydephenylhydrazones. By ERNST GRAHAM LAWS and NEVIL VINCENT SIDGWICK . . .	2085
XXXXVIII.—Theory of Dyeing: the Colour and Molecular State of Picric Acid. By WILLIAM PORTER DREAPER, F.I.C.	2094
XXXXIX.—Formation of Six- and Seven-membered Rings from Derivatives of 2:2'-Ditolyl. By JAMES KENNER and EMILY GERTRUDE TURNER . . .	2101
XXL.—Synthetical Experiments in the Group of the iso-Quinoline Alkaloids. Part II. The Constitution of the Condensation Products of Cotarnine and the Condensation of Cotarnine with Aliphatic and Aromatic Nitro-compounds. By EDWARD HOPE AND ROBERT ROBINSON . . .	2114

ABSTRACTS OF PAPERS PUBLISHED IN OTHER JOURNALS:—

PART I.

Organic Chemistry.

DANIEL (ALONZO SIMPSON). Absorption of Hydrocarbon Gases by Non-aqueous Liquids . . .	i, 829
DIECKMANN (FRIEDRICH). Preparation of β -Dimethyl- α -butadiene . . .	i, 829
DIETZ (WILLIAM M.). Action of Di-iodoacetylene on Organic Bases . . .	i, 829
ESSANIN (G.) and E. SEGRE. Action of Alkaline Solutions on Trichlorinated Organic Compounds . . .	i, 830
FUME (GEORGES) and ALBERT F. O. GERMANN. Fusibility Curves of Gaseous Mixtures: Oxonium Systems Formed by Acetylene, Ethylene, Nitric Oxide, and Methyl Ether . . .	i, 830
FAYN (JULIUS VON) and WILHELM SOHNKE. Primary Aliphatic Dimetro, Nitro-nitrite, and Dialdoxime Compounds . . .	i, 830
FENNER (JAMES R.), BLAIR SEXTON, and H. O. PARKER. Anhydrous Formic Acid . . .	i, 831
ATTIES (HERMANN) and A. DAHLE. Soy Bean Oil . . .	i, 831
EDMANN (ERNST). Preparation and Properties of α -Linolenic Acid from Linseed Oil . . .	i, 832
EYER (KURT H.) and PAUL KAPPELMEIER. Keto-enolic Tautomerism. III. Tautomerism of Ethyl Acetoacetate . . .	i, 832
EYER (KURT H.). Keto-enolic Tautomerism. IV. Ferric Chloride Reaction of Enols . . .	i, 833
FAMBROCK (HEDWIG). Formation of Levulic Acid from Glucosamine, Chitin, and Chitose . . .	i, 834
FEIBLER (HELMUTH) and ALVIN S. WHEELER. The Walden Inversion. VII. Optically Active Leucic (α -Hydroxyisohexonic) Acid and its Transformation into α -Bromoisohexonic Acid . . .	i, 835
FOUGAULT (J.) and C. CHARAUX. Lactaric Acid and Ketostearic Acid Isolated from Fungi of the genus <i>Lactarius</i> . . .	i, 835
FUKUSHI (SUMIO). β -Butanolglycuronic Acid . . .	i, 836
HEIDER (JOHANNES) [with P. LUNGWITZ]. Action of the Chlorides of Dibasic Fatty Acids on Ethyl Sodiaoacetate . . .	i, 836
HEIMISCHER FABRIK GEDEON RICHTER. Preparation of Additive Compounds of Chloral with Amides . . .	i, 836
HEDEFF (A. VON). Hexose Phosphoric Acid Ester . . .	i, 837
HUBERG (CARL) and E. KRETSCHMER. Preparation of Phosphoric Acid Esters of Carbohydrates and of Glycerol . . .	i, 837

GATTERBAUER (JOH.). Nature of the So-called Gallisin in Commercial Starch-Syrup	
OST (HERMANN). Viscosity of Cellulose Solutions	
WERNER (ALFRED). The Asymmetric Cobalt Atom. II.	
LES ÉTABLISSEMENTS POULENC FRÈRES and ERNEST FOURNEAU. Preparation of Mercury Derivatives of Alkali Alkylthiocarbamic Acetates	
ABDERHALDEN (EMIL) and HEINRICH GENDERT. Preparation of Optically Active Polypeptides from Racemic Compounds	
OSWALD (ADOLF). Remarks on Henze's Paper on the History of Iodogorgonic Acid	
SCHENCK (MARTIN). Methylated Guanidines	
HOFMANN (KARL A.) and OSKAR EHRHART. Melamazine from Hydrazine Salt and Dicyanohlamide	
MÜLLER (ERICH) [and, in part, G. WEGELIN, FREDERICK P. TREADWELL, and OTTO DIEFENTHALER]. Prussian Blue and Turnbull's Blue. III.	
HALE (C. F.) and V. E. NUNEZ. Oxidation of Hydrazine. VI. Reaction between Mercuric Oxide and Hydrazine Hydrate in Alcoholic Solution	
THIELE (JOHANNES). The Constitution of Aliphatic Diazo-compounds and of Azoimide	
BYODÉN (ARTUR). Tetra-alkylsilicanes	
EMMERT (BRUNO) and WILHELM ELLER. Organo-metallic Ester Compounds. I. Iodo-tin-ester Compounds	
ZELINSKY (NICOLAI) and ALEXANDER GORSKY. $\Delta^{1:3}$ -Dihydrobenzene [$\Delta^{1:3}$ -cyclohexadiene].	
RUFF (HANS) and W. KERKOVITS. Tetramethylecycloheptatriene	
RISKE (C. N.). Δ^3 -Butenylbenzene	
MEYER (JACOB). Preparation of 2:4:6-Trinitrobenzene from Halogenated Trinitrobenzenes	
ZEREWITTNOFF (TH.) and IWAN VON OSTROMISLENSKY. Barium Oxide as a Reducing Agent. Reduction of Nitrobenzene to Nitroso- and Azobenzene, Aniline, Phenazine, and Ammonia	
HOLLEMAN (ARNOLO F.) and P. CALAND [with T. VAN DER LINDEN and J. P. WIGAUT]. Quantitative Investigation of the Sulphonation of Toluene	
BADISCHE ANILIN- & SODA-FABRIK. Preparation of Chloroalkylaryl-sulphonyl Chlorides	
BADISCHE ANILIN- & SODA-FABRIK. Preparation of a Mixture of 1:4- and 1:5-Dichloronaphthalenes	
PICTET (AMY) and LOUIS RAMSEYER. A Constituent of Coal	
WIELAND (HEINRICH). Triphenylmethyl Peroxide. The Chemistry of Free Radicals	
FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING. Preparation of Phenylbenzylidimethylammoniumdisulphonic Acid	
HALBAN (HANS VON). Kinetics of Ammonium Salts	
KAST (HERMANN). The Metallic Salts of Trinitrophenols and Trinitro-cresols	
AKTIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION. Preparation of 4-Chloro-6-nitro-2-aminophenol	
DIEPOLDER (EMIL). Derivatives of 1:2-Dimethylbenzene [o-Xylene]. II.	
JONA (TEMISTOCLES) and G. B. POZZI. Chloroguaiacols	
FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING. Preparation of 1:4-Dihydroxynaphthalene Monalkyl Ethers	
BARGELLINI (GUIDO) and ERMANNO MARTEGIANI. Some Derivatives of Hydroxyquinol. IV.	
BARGELLINI (GUIDO) and S. AURELI. Some Derivatives of Hydroxyquinol. V.	
FABINYI (RUDOLF) and TIBOR SZÉKI. A Nitroso-compound of Dimethoxyphenol, and its Derivatives	
LEDERER (CHARLES). Aromatic Tellurinium Compounds with the same Hydrocarbon Residue	

CONTENTS.

	PAGE
TIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION. Preparation of <i>o</i> - <i>p</i> -Alkylhydroxyphenylethylamines and their <i>N</i> -Alkyl Derivatives	i, 857
STILES (HERMANN) and A. DAHLE. Phytosterols of Soy Bean	i, 858
RTOLO (PARQUALE). Action of Chlorine on "Saccharin"	i, 858
BBENFABRIKEN VORM. FRIEDR. BAYER & Co. Preparation of Esters of Cinnamic Acid	i, 858
OBRE (HANS) and FRITZ REUSS. Refraction of Light by <i>allo</i> - and <i>iso</i> -Cinnamic Acids	i, 859
OBRE (HANS). Transformations of <i>allo</i> - and <i>iso</i> -Cinnamic Acids in the Fused and Crystalline States	i, 859
IBER (C. N.). Oxidation of <i>allo</i> -Cinnamylidenesuccinic Acid	i, 860
YNOLDE (GLAUBER P.). Reaction between Organomagnesium Compounds and Cinnamylidene Esters. III. Reactions with the Isomeric Methyl Esters of Cinnamylidenesuccinic Acid	i, 860
HLER (ELMER P.), GERTRUDE L. HERITAGE, and A. L. MACLEOD. Reaction between Unsaturated Compounds and Organic Zinc Compounds. II.	i, 862
IBATI (ARISHIO). Crystallographic Study of Potassium <i>p</i> -Hydroxybenzoate	i, 864
ELLER (GUSTAV) [with FRIEDRICH FRANTZ and HEINRICH JÜRGENS]. <i>o</i> -Nitrophenylglyoxylic Acid	i, 864
EYER (KURT H.). Keto-enolic Tautomerism. V. Desmotropy of Methyl Benzoylacetate	i, 865
BBENFABRIKEN VORM. FRIEDR. BAYER & Co. Preparation of <i>m</i> -Hydroxy- <i>β</i> -phenylpropionic Acid Alkyl Ethers and their Salts	i, 865
RLÄNDER (DANIEL) [and, in part, A. FRIEDBERG, CH. VAN DER MEER, L. ROSENTHAL, M. E. HUTH, and M. VON BODECKER]. New Reactions of Cyanogen and Acyl Cyanides	i, 865
STÄTZORI (AUGUSTIN), J. PAULUS, and R. PERRIN. Condensation of <i>p</i> - and <i>o</i> -Methoxymandelonitriles with Phenols and Phenolic Ethers	i, 868
AYER (FRITZ). Diphenyl Derivatives	i, 869
LINNEY (NICOLAI) and NIKOLAUS GLINKA. Simultaneous Reduction and Oxidation by Catalysis	i, 870
ALLE & Co. [Preparation of Dichloro- <i>o</i> -carboxyphenylthioacetic Acid]	i, 871
UER (HUGO). Action of Organo-magnesium Compounds on 4-Methoxyphthalic Anhydride	i, 871
UER (HUGO) and EWALD WOLZ. Action of Organo-magnesium Compounds on Homophthalic Anhydride	i, 871
EYER (RICHARD) and KARL MEYER. Phthaloids of 3:5:3':5'-Dihydroresorcinol (3:5:3':5'-Tetrahydroxydiphenyl)	i, 872
SCHKE (ERICH) [with MARIAN WINOGRAN-FINKEL and GEORG KÖHRES]. Synthesis of Chrysene	i, 873
SCHER (EMIL) and KARL FREUDENBERG [with KURT HOESCH and R. LEPSIUS]. Methylcarbonato-derivatives of Phenolcarboxylic Acids and their Use for Synthetic Operations. V.	i, 874
UBERG (CARL) and E. KRETSCHMER. <i>p</i> -Chesolglyconic Acid	i, 875
IRTH (P. H.). Cherry-laurel Water and Solutions of Benzaldehyde and Hydrocyanic Acid in Water	i, 875
WORZOW (VICTOR). Hydrogenation of Hydroaromatic Compounds	i, 876
ADINGER (HERMANN) and N. KON. Ketens. V. Reactivity of the Carbonyl Group	i, 876
TERSON (PETER P.). Stereoisomeric Chloroimino-ketones	i, 879
SCHKE (WALTHER). 5-Phenylbutyl Ketones and 5-Phenylvaleric Acid	i, 880
UISE (EDMOND E.) and I. HERMAN. <i>β</i> -Keto- <i>α</i> -dialkyl Alcohols. III.	i, 880
UER (HUGO) and HEDWIG DIETTERLE. The Nature of the Carbon Double Linking. III. The Bromides of Anisylidenecinnamylidenesuccinone	i, 881
ILLGEROOT (CONRAD) and BRUNO ALBERT. Acylated Phenanthrenes and Some of their Derivatives	i, 882
KHMANN (FRIEDRICH). The Two Forms of <i>o</i> -Benzoquinone	i, 883

BAMBERGER (EUGEN) and LOUIS BLANCY. Action of Magnesium Methyl Iodide on <i>p</i> -Xyloquinone and Toluquinone	
FABRIK-FABRIKEN VORM. FRIEDR. BAYER & CO. [Preparation of Anthraquinone Derivatives]	
RADIČEK ANILIN- & SODA-FABRIK. Preparation of Aminoanthraquinones and of Aminonaphthanthraquinones or their Derivatives	
RADIČEK ANILIN- & SODA-FABRIK. Preparation of Condensation Products in the Anthracene Series	
RADIČEK ANILIN- & SODA-FABRIK. Preparation of Anthraquinone Condensation Products	
FISCHER (OTTO) and HANS GROSS [with P. NEBER]. Chrysophanic Acid, Frangula-Emodin, and Some Oxonium Compounds of Anthracene Derivatives	
OESTERLE (OTTO A.). Relationship between Chrysophanic Acid, Aloe-Emodin, and Rhein	
OESTERLE (OTTO A.) and W. STPKENS-TOXOPÉUS. Constitution of Frangula-Emodin	
SCHOLL (KOLAND) [with G. VON WOŁODKOWITSCH]. Existence of Quinonoid Properties in Anthraquinone Derivatives	
BESCHKE (ERICH) [with FRANZ DIEHM]. 2:8- or <i>amphi</i> -Chrys-quinone	
MURAT (MARCEL). Condensation of Menthones with Organo-magnesium Compounds. Synthesis of Homologues of Menthol	
WALLACH (OTTO). Terpenes and Ethereal Oils. CVII. [Constitution and Synthesis of Pinolone and of Dihydropinolone (3-Acetylisopropyl-cyclopentane)]	
BLUMANN (A.) and OTTO ZRITSCHEL. Degradation of Nerol and its Constitution	
KAZAY (ENDER VON). Influence of Water on the Rotatory Power of Camphor Solutions	
HILDITCH (THOMAS P.). Effect of Molecular Symmetry on the Optical Activity and Relative Rotatory Power of Aromatic Position Isomerides	
SCHIMMEL & Co. [Essential Oils]	
ROURE-BERTRAND FILS, L. LABAUNE, and J. DUPONT. [Essential Oils]	
FRANCESCONI (LEO) and G. SANNA. Essential Oil of <i>Aspleurum fruticosum</i> . II.

BIN (HARRY M.). Crystalline Alkaloid of <i>Calycanthus glaucus</i> . IV. Some Salts of a New Quaternary Base obtained by Methylating iso-Calycanthine	i, 903
DAUS (ADOLF). Colchicine. I. and II.	i, 904
KER (HERMAN). Preparation of Hydrastinine Salts	i, 906
UND (MARTIN) and KARL LEDERER. Action of Organic Magnesium Compounds on Hydrastinine	i, 906
MES (W. C.). Formation of Alkaloidal Periodides	i, 907
HORR (ROLAND) and F. DICKHAUSER (and, in part, C. D'AVIS). Methylation of the Alcoholic Hydroxyl Group in Morphine, Codeine, and the Methylmorphimethines	i, 908
UND (MARTIN) and EDMUND SPRYER. Codeine Oxide	i, 909
UND (MARTIN) and KARL LEDERER. Cotarnine. VI.	i, 910
UND (MARTIN) and OTTO KUPFER. Stereochemistry of Nitrogen Compounds. Isomeric Bishydrocotarnines	i, 911
IOLTZ (MAX). Alkaloids of Pareira Root	i, 913
IMBT (ERNST) and D. BRUNS. Brucine Polyhydrosulphides	i, 913
RELL (GEORGE FRANCIS). Dihydroterpenylamine	i, 914
HN (WILLIAM M.) and ALBERT H. DEWEY. Action of Carbon Tetrabromide on Organic Bases	i, 914
IEBER (JOHANNES). Homologous Nature of Anthranil and Methylanthranil	i, 915
UFMANN (ADOLF) and J. M. PÉLA Y JANINI. Constitution of the ψ -Bases of Quinoline. II.	i, 915
ELTING (EMILIO) and ALEX. HERZBAUM. Condensation Products of Isatic Acid and Hydroxythionaphthen, Indanilone, and Indanone	i, 917
LEE & Co. [Preparation of Carbazole Derivatives]	i, 917
SA (ROBERTO) and A. TERNI. Action of Hydroxylamine on Ketones of the Type $R \cdot CH_2 \cdot CH \cdot CH \cdot COPh$	i, 918
NDT (FRITZ). Aromatic ψ -Thiocarbamides and their Conversion into Aryl <i>ortho</i> -Thiocarbonates	i, 918
NZIO (GIACOMO). Conversion of Nitroaldehydes into Cyanoaldehydes	i, 920
LAZZO (F. CARLO) and RAFFAEL LIVERANI. Syntheses of Pyrazolones from a Derivative of γ -Pyrone	i, 920
UER (HUGO) and HERMIO DIESTERLE. The Pyrazoline Transformation of Unsaturated Hydrazones	i, 921
AUTLECHT (CHARLES A.). Hydantoina. IV. 2-Thio-1-phenyl-hydantoina from Some α -Amino-acids	i, 922
IEBLER (HENRY L.), CHARLES HOFFMAN, and TREAT B. JOHNSON. Hydantoina. V. Synthesis of 3:5-Dichlorotyrosine	i, 923
INSON (TREAT B.) and NORMAN A. SHEPARD. Pyrimidines. LIII. Condensation of Ethyl Formate and Ethyl Oxalate with Some Pyrimidinethioglycolates	i, 924
DISCHE ANILIN- & SODA-FABRIK. Preparation of Halogenated Derivatives of Indigotin	i, 925
RENFABRIKEN VORM. FRIEDR. BAYER & Co. [Preparation of Methylindanthren]	i, 925
NZIO (GIACOMO) and C. GASTALDI. Action of Nitrous Acid on Substituted Hydrazidines	i, 925
TO (RUDOLF). Preparation of Secondary 4-Dimethylamino-1-phenyl-2:3-dimethyl-5-pyrazolone Citrate	i, 926
ERMANN (FRIEDRICH) and JOSÉ RIERA Y PUNTI. Isomeride of apo-Safranine and the Third Isomeride of Phenosafranine	i, 926
ERMANN (FRIEDRICH) and A. MASSLENIKOFF. Third Isomeride of apo-Safranine	i, 927
ERMANN (FRIEDRICH) and JOSÉ RIERA Y PUNTI. Synthesis of Naphthaphenazine Derivatives	i, 927
RENFABRIKEN VORM. FRIEDR. BAYER & Co. Preparation of Iminoalkyl Derivatives of Azimino- <i>o</i> -toluidides	i, 928
EN (GEORGE). Diguanides	i, 928

-The Active Constituents of the Indian Solanaceous Plants Datura Stramonium, D. fastuosa, and D. Metel.

By ALBERT EDWARD ANDREWS.

Among the solanaceous plants *Datura Stramonium*, *D. fastuosa*, and *D. Metel* grown in Europe have been investigated by several authors, yet with the single exception of an article in the Bulletin of the Imperial Institute" (1905, 2, 224) giving the results of the examination of a specimen of *Datura Stramonium* no chemical investigation of these plants as grown in India has yet been published, notwithstanding that their medicinal and poisonous properties have long been recognised in this country. For this reason, and with a view to their possible medicinal utilisation, samples of these plants have from time to time been investigated in the Scientific and Technical Department of the Imperial Institute, and it is thought that it would be of interest to record the results obtained, especially as differences of climate and soil are known to produce considerable alteration in the constituents of plants. In carrying out this investigation, the chief object has been to determine the amount and nature of the alkaloidal constituents, and compare them with those from the same species elsewhere.

Indian species of *Datura* grow wild, and have long been known to the people of India for their intoxicating and narcotic properties. *D. Stramonium* is met with in the temperate Himalaya, Baluchistan and Kashmir to Sikkim. *D. fastuosa* is a small plant found all over the tropical parts of India, and is said to be the most common and abundant species. *D. Metel* grows chiefly in the North-West Himalaya and the mountains of the Deccan. The material used in the present investigation was kindly sent to me by the Officiating Reporter on Economic Products to the Government of India at the instance of Professor Wyndham R. Dunstan, whose direction this work has been carried out.

EXPERIMENTAL.

Extraction and Estimation of the "Total Alkaloid."

The following was the general method employed in the examination of the various samples:

The finely ground material is exhausted by percolation with cold solvent, and the solvent distilled off under diminished pressure until

practically the whole has been removed. The semi-solid extract is well agitated with small quantities of warm water, and then with very dilute sulphuric acid to ensure the complete separation of the alkaloid. The filtered aqueous acid liquid is shaken with ether, then made weakly alkaline with dilute ammonia, and extracted several times with chloroform to extract the alkaloid. Each portion of chloroform used to extract the alkaloid is in turn transferred to a second separator, washed with a little water, then dried with anhydrous sodium sulphate, and the total chloroform extract is distilled under diminished pressure at a temperature not exceeding 40°. The total crude alkaloid thus obtained is then purified at the same time separated into two fractions. The residual alkaloid is dissolved in a small excess of very dilute sulphuric acid, and the solution, filtered if necessary, is shaken with ether to remove traces of colouring matter and other impurities soluble in ether; the aqueous liquid is then made slightly alkaline with ammonia, and extracted with three or four portions of ether, then with chloroform. Both the ether and chloroform solutions of the alkaloid are washed and freed from water as before noted. The two fractions of alkaloid obtained by the distillation of the solvents are dried in a vacuum desiccator and weighed. The combined weights of the two extracts give the "total alkaloid" contained in the sample.

The separation of the total alkaloid into two fractions is done as a preliminary step in the identification of the constituent alkaloids. If more than one alkaloid be present a partial separation is obtained, and the identification of the alkaloids facilitated.

The Identity of the Alkaloids.

In cases where hyoscyamine is the only alkaloid, or else lauroyl predominates, the crystalline nature of the fraction extracted with chloroform indicates its presence; otherwise, the total alkaloid weighed is amorphous. The aurichlorides are next prepared from each of the two fractions, and this salt is then fractionally crystallized until fractions of definite melting point are obtained. The alkaloids are then recovered from these fractions, and are further examined, following the clue to their identity given by the melting points of the gold salts.

In the case of scopolamine the identity was established by comparing melting points and general properties of the aurichloride, hyoscyamine bromide, and picrate, as compared with the same salts prepared and examined under identical conditions from a sample of Me. scopolamine hydrobromide represented as agreeing with E. Schmidt's alkaloid, and also with the tests of the German Pharmacopoeia.

DATURA STRAMONIUM, D. FASTUOSA, AND D. METEL. 1873

was complete agreement between the scopalamine isolated the different plants and this sample of alkaloid. Hyoscyamine isolated from the different plants in the course of this investigation was obtained in white, lustrous, hair-like crystals, melting at 106°, and having $[\alpha]_D -20.75^\circ$ at 21°. The corresponding salts were prepared:

The aurichloride	melting at 159.5°.
The hydrobromide	" " 149—150°.
The sulphate	" " 209—210°.
The picrate	" " 162—163°.

As will be seen from the tabulated results, there was no indication of atropine in any of the *Datura Stramonium* or *D. fastuosa* samples. In the case of *D. Metel*, however, there was evidence of

Results of examination of *Datura Stramonium* samples from the Punjab.

No. of plant.	Percentage of total alkaloid.		Alkaloids present.	Remarks.
	In material as received.	Calculated on water-free material.		
Sample of small plant	0.23	0.25	Hyoscyamine and scopalamine	These alkaloids were present in the proportion of about 3 or 4 to 1 respectively
Sample of large plant	0.23	0.26	Hyoscyamine and scopalamine	There appeared to be rather less scopalamine present than in the previous samples
Sample of small plant	0.42	0.45	Hyoscyamine only	There was no indication of the presence of any other alkaloid
Sample of large plant	0.38	0.41	Hyoscyamine and scopalamine	These alkaloids were present in the proportion of about 4 to 1 respectively
Sample of small plant	0.42	0.46	Hyoscyamine and scopalamine	These alkaloids were present in the proportion of about 4 to 1 respectively
Sample of large plant	0.43	0.46	Hyoscyamine only	There was no indication of the presence of any other alkaloid
Sample of both large and small plants	0.19	0.21	Hyoscyamine and scopalamine and another alkaloid not identified	The hyoscyamine and scopalamine were present in about equal quantities
Sample of small complete plant	0.20	0.22	Scopolamine only	There was no indication of the presence of any alkaloid other than scopolamine

* The large quantity of potassium chloride and nitrate present in this sample was particularly noticeable. The alcoholic percolate was found to contain an amount of these salts which, calculated as K_2O , equalled 1.42 per cent. of the roots.

Results of examination of *Datura Stramonium* samples from Madras.

Part of Plant.	Percentage of total alkaloid.		Alkaloids present.	Remarks.
	Calculated on			
	In material as received.	water-free material.		
Leaves	0.38	0.42	Hyoscyamine and scopolamine	These alkaloids present in the proportion of about 1 respectively
Seeds	0.173	0.186	Hyoscyamine and scopolamine	These alkaloids present in the proportion of about 1 respectively, was in addition a small quantity of pure alkaloid, probably hyoscyamine.

the presence of a small proportion of atropine, but the amount was insufficient fully to establish its identity. In these cases the chlorido was obtained in non-lustrous crystals, melting at 135—1 and the alkaloid recovered from these was optically inactive.

The tabulated statements give the results obtained with different parts of the Indian solanaceous plants, *Datura Stramonium*, *D. fastuosa*, and *D. Metel*, and show (1) the amount of total alkaloids contained in the particular part of the plant, (2) the constituents of the alkaloids which have been identified, and (3) the approximate proportions of the different alkaloids in those cases where more than a single alkaloid is present.

The following points may be noted from the tabulated results for the *Datura Stramonium* samples:

In the samples from the Punjab the percentage of total alkaloids in similar parts of the large and small plants was practically the same, whether in the fruits, stems, or leaves.

The alkaloids in all of the samples were either hyoscyamine or scopolamine, or both in varying proportions. Only in the case of the roots was there evidence of a third alkaloid. There was no indication of atropine in any of the samples.

Hyoscyamine was the only alkaloid found in the leaves of the small plant and in the fruits of the large plant. In each case it was present to the extent of nearly 0.5 per cent., and could readily be isolated in a crystalline condition.

Scopolamine was the only alkaloid in the very small plant. With this one exception, hyoscyamine was the predominant alkaloid. The proportion of hyoscyamine and scopolamine in the stems of the large and small plants shows very little variation, but in the

the fruits and the leaves it is noticeable that scopolamine is in the leaves of the small plant and in the fruits of the plant. The following table showing the distribution of the alkaloids in the different parts of the small and large plants makes these points more clearly. It should be mentioned that the plants were collected at one time in the same district of the Punjab.

	Stems.	Leaves.	Fruits.	Whole plant.
Small	—	—	—	Scopolamine
	3 or 4 parts of hyoscyamine to 1 part of scopolamine	Hyoscyamine only	4 parts of hyoscyamine to 1 part of scopolamine	—
	Hyoscyamine and scopolamine. Rather less of the latter alkaloid than in stems of small plant	4 parts of hyoscyamine to 1 part of scopolamine	Hyoscyamine only	—
				Hyoscyamine and scopolamine in about equal proportions, and a small proportion of a third alkaloid not identified

In the following table the percentages of total alkaloid found in Indian specimens of *Datura Stramonium* are compared with recorded figures for similar parts of the plant grown elsewhere:

of plant.	Indian specimens.	Specimens from other countries.
Seeds	0.188 0.46*	0.21 to 0.43 (European) 0.35 (Egyptian)
Leaves	0.41 to 0.45	Up to 0.4 (European)
Stems	0.25 to 0.26	Main stems 0.09 Upper branches 0.36 Average 0.22
Roots	0.214	Main roots 0.10 Rootlets 0.25 Average 0.17

* This was the percentage in two samples of the fruits, that is, seeds and stems together; the alkaloid is chiefly present in the seeds, consequently the percentage for the fruits is lower than it would be for the seeds alone.

These figures clearly indicate that Indian *Datura Stramonium* makes a favourable comparison with the European and Egyptian plants as regards the amount of total alkaloid that it contains. In the plants from the latter sources, hyoscyamine is generally found to be the only or the main alkaloid present, being in some cases associated with a small proportion of atropine. The presence of scopolamine in some of the Indian samples appears, therefore, as a point of difference.

Results of examination of *Datura fastuosa* var. black, from Assam.

Part of plant.	Percentage of total alkaloid in material as received.	Alkaloids present.	Remarks.
Twigs and leaves	0.119	Scopolamine and hyoscyamine	These alkaloids were present in the proportion of about 4 to 1 respectively. There was in addition a small proportion of amorphous alkaloid.
Roots	0.101	Scopolamine only	There was no indication of either hyoscyamine or atropine. A small proportion of amorphous alkaloid was present.
Fruits	0.202	Scopolamine only	There was no indication of either hyoscyamine or atropine. A small proportion of amorphous alkaloid was present.

It is noticeable in the above results for *D. fastuosa* that scopolamine is the only alkaloid in the roots and fruits, and is the predominant alkaloid in the twigs and leaves of the plant. The seeds of this species grown in Europe contain about the same amount of alkaloid as that found for the Indian plant, and contain scopolamine as the main alkaloid associated with a small proportion of hyoscyamine and a little atropine.

Results of examination of *Datura Metel* samples from the Punjab.

Part of plant.	In material as received.	Percentage of total alkaloid.		Alkaloids.	Remarks.
		Calculated on			
Leaves from Lyallpur	0.22	water-free material.	0.25	Scopolamine	A small proportion of another alkaloid, apparently atropine, was present.
Seeds from Lyallpur	0.21		0.23	Scopolamine	Ditto
Seeds from Patiala	0.23		0.25	Hyoscyamine and scopolamine	These alkaloids were present in the proportion of about 2 to 1 respectively. A small proportion of another alkaloid was present, which appeared to be atropine.
Capsules from Patiala	0.10		0.12	Scopolamine only	No indication of the presence of any other alkaloid.

E. Schmidt (*Arch. Pharm.*, 1905, 243, 309; 1910, 248, 641) examined *D. Metel* cultivated in France, and found that scopolamine is present in all parts of the plant and is unaccompanied by any notable quantity of other mydriatic bases. The dried leaves

contain 0.55 per cent., and the seeds 0.5 per cent., of scopolamine. Kircher (*Arch. Pharm.*, 1905, **243**, 309) confirmed Schmidt's figures, and drew the conclusion that scopolamine formed the bulk of the alkaloid, being accompanied by only small proportions of hyoscyamine and atropine.

On comparing these results with those in the table, it appears that in the Indian plant the percentage of total alkaloid in the seeds and in the leaves is only about one-half what it is in the European plant. The *D. Metel* seeds from Patizla appear to be exceptional in containing hyoscyamine as the predominant alkaloid, but the other three samples resemble the European plant in so far that scopolamine is almost unaccompanied by other mydriatic alkaloids.

SCIENTIFIC and TECHNICAL DEPARTMENT,
IMPERIAL INSTITUTE, S.W.

CCXL.—A New Stereoisomeride of Cyanodihydrocarvone.

By ARTHUR LAPWORTH and VICTOR STEELE.

It has been shown that *d*-carvone unites with hydrogen cyanide in the presence of potassium cyanide at the ordinary temperature, yielding, in the first instance, a cyanodihydrocarvone:

This substance contains three asymmetric carbon atoms, labelled 1, 2, and 3, whilst the original carvone contains the first only (*Trans.*, 1906, **89**, 945 *et seq.*, and 1819 *et seq.*). *d*-Carvone may theoretically give rise to four stereoisomeric cyanodihydrocarvones, and evidence of the existence of at least two was obtained on a former occasion by showing that the one which had then been isolated in a pure form exhibited mutarotation in the presence of a trace of sodium ethoxide. It has since been observed that if the addition of the hydrogen cyanide takes place in hot solutions, a crystalline cyanodihydrocarvone is formed in considerable quantity, which has a rotatory power in the opposite sense to that of the isomeride previously described, and cannot be converted into the latter by traces of alkali. It is probable that it represents the third possible isomeride, and it appears to be partly converted into the fourth isomeride by small quantities of alkali in alcoholic

solution, as it then exhibits a small but definite mutarotation; the final value of the rotatory power attained is, however, about $[\alpha]_D - 39.00^\circ$ instead of $[\alpha]_D + 15.4^\circ$, the value shown by the cyano-compound first discovered.

It would thus appear that the four isomerides may be divided into two pairs, the two members of each pair being dynamic isomerides at the ordinary temperature. At higher temperatures, in the presence of alkalis, all four are probably dynamic isomerides, as in this case hydrogen cyanide may be alternately eliminated and reabsorbed with considerable rapidity. It is known that the sign of an asymmetric carbon atom in the complex $\text{CH} \cdot \text{CO} \cdot \text{C} \cdot$ may undergo inversion, causing the effect of mutarotation in the presence of traces of alkalis. As the hydrogen atom in the group $>\text{CH} \cdot \text{CN}$ appears usually to be less labile than that in the group $>\text{CH} \cdot (\text{CO} \cdot \text{C} \cdot)$, it appears highly probable that the mutarotations observed with the two crystalline cyanodihydrocarvones at the ordinary temperature may be attributed to the presence of the latter complex. If this is so, then the new cyano-compound and its dynamic isomeride differ from those obtained by the synthetic process at the ordinary temperature, by a change in the sign of the asymmetric carbon atom to which the cyano-group is attached. It was proved that the asymmetric carbon atom of the carvone complex itself had been unaffected, as both the crystalline cyano-compounds yielded pure *d*-carvone when boiled with solutions of alkali containing suspended ferrous hydroxide.

The new nitrile yields a new *amide* when hydrolysed by cold hydrogen chloride, but the carboxylic acids which are formed on further hydrolysis are identical with those previously obtained.

EXPERIMENTAL.

neo-Cyanodihydrocarvone, $\text{C}_{11}\text{H}_{15}\text{ON}$.

This substance was accidentally obtained, in the first instance, as the result of using a hot, instead of a cold, solution of potassium cyanide during the preparation of α -cyanodihydrocarvone by the process otherwise as previously described (*Trans.*, 1906, **89**, 950); the yield being very small. It was found later that the following process gave yields of about 85 per cent. of the theoretical. *

Thirty grams of potassium cyanide (100 per cent.), 80 c.c. of water, and 80 c.c. of spirit are together heated to boiling on the waterbath, and a boiling mixture of 60 grams of carvone and 30 c.c. of ethyl acetate is then added, heating being continued until complete solution takes place, an operation which usually occupies

about twelve to fifteen minutes. The whole is cooled and diluted with water, when the greater part of the nitrile separates in a solid form, and is removed by filtration, the filtrate being extracted with ether. The ethereal extract is washed with water, the solvent removed, and the residue added to the precipitated nitrile. The compound is purified by repeated crystallisation from alcohol:

0.2018 gave 0.5500 CO_2 and 0.1549 H_2O . $\text{C} = 74.3$; $\text{H} = 8.3$.

$\text{C}_{11}\text{H}_{11}\text{ON}$ requires $\text{C} = 74.6$; $\text{H} = 8.5$ per cent.

Experiments were made with the object of ascertaining whether the β -cyanodihydrocarvone could be obtained from the α -nitrile by the action of small quantities of alkalis or sodium ethoxide, but although change certainly occurs, the oils which are formed do not readily yield anything of a definite character. β -Cyanodihydrocarvone resembles its isomeride in regard to its behaviour towards the usual solvents, and crystallises from alcohol or benzene in needles, melting at 84° .

0.3618, made up to 25 c.c. with absolute alcohol, gave, in a 2-dm. tube, $\alpha = 1.22^\circ$, whence $[\alpha]_D = 42.1^\circ$. After the addition of a trace of sodium ethoxide, the observed rotation was -1.13° , whence $[\alpha]_D = -30.00^\circ$. That this slight fall was in the main due, as is the case of its isomeride, to isodynamic change seems probable, as the solution on spontaneous evaporation yielded a viscid liquid which crystallised only after some time; the solid then obtained was, however, identical with the original substance (compare *Trans.*, 1906, 89, 951).

The nitrile distils under the ordinary pressure without undergoing any appreciable isomeric change, but with slight charring. It behaves towards potassium permanganate and bromine as an unsaturated compound, exhibits distinct basic properties, dissolving appreciably in concentrated hydrochloric acid, and is not precipitated from the solution on addition of water. Although it is not quickly decomposed by a hot 5 per cent. solution of potassium hydroxide in alcohol, it rapidly loses hydrogen cyanide when boiled with concentrated alcoholic potassium hydroxide, carvone being liberated, and the change is more rapid and complete if ferrous hydroxide is also present to unite with the potassium cyanide as it is formed. In one experiment this nitrile was heated with a concentrated methyl-alcoholic solution of potassium hydroxide containing suspended ferrous hydroxide, for about fifteen minutes, the liquid being then diluted with water and distilled in a current of steam. The distillate was extracted with ether, the ethereal solution washed with a little water, dried, and freed from solvent. On distillation of the residue, the fraction boiling at 225° was collected;

this had the odour of ordinary carvone, and had the same rotatory power.

0.335, made up to 25 c.c. with absolute alcohol, gave, in a 2-dm. tube, $\alpha + 1.68^\circ$, whence $[\alpha]_D^{25} + 62.7^\circ$, whilst carvone has $[\alpha]_D^{25} + 62^\circ$ to 62.5° in this solvent.

The action of amyl nitrite and sodim ethoxide on the new nitrile was investigated.

Twelve grams of the pure nitrile were added to an ice-cold solution of 1.6 grams of sodium dissolved in 40 c.c. of absolute alcohol; 10 grams of amyl nitrite were then added slowly, the temperature being kept at 0° . After twelve hours, water (500 c.c.) was added, and the solution filtered from a little tarry matter. The filtrate was saturated with carbon dioxide, when a white, voluminous solid separated. This was collected, and after crystallisation from alcohol weighed 11 grams. It crystallised in slender needles, melting at $138-139^\circ$, and was identical with the active lactam obtained by Lapworth and Wechsler (*Trans.*, 1907, 91, 981) by a similar treatment of ordinary cyanodihydrocarvone; thus its melting point was not affected by admixture with that compound, and its rotatory power had the same value.

0.2055, made up to 25 c.c. with absolute alcohol, gave, in a 2-dm. tube, $\alpha + 1.99^\circ$, whence $[\alpha]_D^{25} + 121.04^\circ$.

The compound described by Lapworth and Wechsler had $[\alpha]_D^{25} + 121^\circ$ in alcohol.

The phenylhydrazone, $\text{CN}\cdot\text{C}_{10}\text{H}_{15}\cdot\text{N}\cdot\text{NHPh}$, was prepared by warming together equimolecular proportions of the nitrile and phenylhydrazine for half an hour. It was purified by crystallisation from alcohol:

0.1836 gave 0.5075 CO_2 and 0.1305 H_2O . $\text{C}=75.4$; $\text{H}=7.9$.

$\text{C}_{17}\text{H}_{21}\text{N}_3$ requires $\text{C}=75.4$; $\text{H}=7.9$ per cent.

It closely resembles the isomeric hydrazone previously described (*loc. cit.*, p. 952), but separates from alcohol in slender needles, and is somewhat unstable, changing spontaneously into a dark red syrup. It melts and decomposes between 113° and 116° , according to the rate of heating.

The oxime, $\text{CN}\cdot\text{C}_{10}\text{H}_{15}\cdot\text{NOH}$, crystallises from alcohol in flat needles, which melt at 18° with slight darkening. In other respects, it has much the same properties as the oxime of the α -cyanodihydrocarvone:

0.1993 gave 0.5007 CO_2 and 0.1512 H_2O . $\text{C}=68.5$; $\text{H}=8.4$.

$\text{C}_{11}\text{H}_{16}\text{ON}$, requires $\text{C}=68.7$; $\text{H}=8.3$ per cent.

Formation of Carboxylic Acids from β -Cyanodihydrocarvone.

Five grams of nitrile were left in contact with 40 grams of saturated aqueous hydrogen chloride for five days, the hydrolysis being completed by heating for two hours on the water-bath. The acid products of hydrolysis were finally obtained as a crystalline mass, which was rapidly washed with carbon disulphide. A colourless mass was left, which was crystallised from ethyl acetate:

0.1620 gave 0.3997 CO_2 and 0.1190 H_2O . $\text{C}=67.3$; $\text{H}=8.2$.

$\text{C}_{10}\text{H}_{15}\text{O}\cdot\text{CO}_2\text{H}$ requires $\text{C}=67.4$; $\text{H}=8.2$ per cent.

0.1463 required 7.5 c.c. $N/10$ - NaOH for neutralisation, using phenolphthalein as indicator, hence equivalent = 195. The number calculated for a monobasic acid, $\text{C}_{11}\text{H}_{16}\text{O}_2$, is 196.

The product, as in the case of the hydrolysis of α -cyanodihydrocarvone, was found to be a mixture, the melting point being indefinite between 85° and 110° . As the whole did not melt below 100° , the mixture was placed on porous porcelain, and allowed to remain in the steam-oven for four hours. A small quantity of material was left, which appeared to be homogeneous, and after one or two crystallisations melted sharply at 135° . The quantity obtained in a pure state, however, was too small for further investigation.

On another occasion the crude product of hydrolysis was extracted repeatedly with boiling water, a treatment which left a dark-coloured, insoluble gum behind. On cooling the extract, the acids crystallised as a mixture of pure white needles and flat plates. By crystallisation from carbon tetrachloride, two fractions were obtained, the first being only sparingly soluble, and the other fairly readily so in that solvent. The first fraction was recrystallised, and separated in plates, melting sharply at 142 – 143° ; it was proved to be identical with the β -acid obtained from ordinary cyanodihydrocarvone by the "mixed melting-point" method. The other fraction was crystallised twice from ethyl formate, and then melted sharply at 97° ; it was proved to be identical with the α -acid obtained from ordinary cyanodihydrocarvone.

β -Cyanodihydrocarvonecarboxylamide, $\text{NH}_2\cdot\text{CO}\cdot\text{C}_{10}\text{H}_{15}\text{O}$.—The nitrile (5 grams) was allowed to remain with saturated hydrobromic acid (10 c.c.) until it had dissolved, and a drop of the resulting liquid gave no precipitate on addition to water, when, on diluting with water and neutralising with sodium carbonate, the amide slowly separated in crystalline form. It was purified by crystallisation from alcohol:

0.2187 gave 0.5452 CO_2 and 0.1699 H_2O . $\text{C}=67.9$; $\text{H}=8.6$.

$\text{C}_{11}\text{H}_{17}\text{O}_2\text{N}$ requires $\text{C}=67.7$; $\text{H}=8.7$ per cent.

The amide, which closely resembles its isomeride in solubility in organic media, separates from ethyl acetate in flat needles, which, when heated, darken slightly at 200° , and melt at 218° . When it was mixed with the amide obtained from the α -nitrile, melting occurred at 180° , so that the compounds are not identical.

When the new amide is almost fully hydrolysed by means of hot alcoholic potassium hydroxide, the acidic product is a mixture of α - and β -dihydrocarvonecarboxylic acids. If, however, the heating occupies only a few minutes, and the resulting liquid is poured into water and acidified, a crystalline precipitate of an acid is obtained, which, after one crystallisation from water, melts at 141 – 142° , being practically pure α -dihydrocarvonecarboxylic acid, as was shown by the "mixed melting-point" method. It has previously been shown (Trans., 1906, 89, 958) that the amide obtained from ordinary cyanodihydrocarvone, if hydrolysed by boiling with alcoholic potassium hydroxide, is converted into a dihydrocarvonecarboxylic acid. These experiments have since been repeated, the whole being heated for a short time only; the product, after one crystallisation from water, melted sharply at 97° , and was identical with the β -carboxylic acid, whilst the nearly pure α -acid was obtained on a former occasion by one of us.

The observations as to the conditions which lead to the production of either or both carboxylic acids from the isomeric amides are thus somewhat contradictory, so that the relationship between the compounds remains an open question.

CCXII.—*Some Properties of Phenyl isoPropyl Ketone.*

By ARTHUR LAPWORTH and VICTOR STEELE.

It is well known that ketones which contain the group $\cdot\text{CO}\cdot\text{CH}_2\cdot$ condense readily with certain carboxylic esters in presence of sodium or sodium ethoxide, yielding β -diketones and alcohol, whilst ketones which contain only the complex $\cdot\text{CO}\cdot\dot{\text{C}}\text{H}$ do not take part in such a condensation. The theory of the mechanism of the reaction has been discussed on numerous occasions, and reference may be made to a paper by Clarke, Lapworth, and Wechsler (Trans., 1908, 93, 30) for an historical summary.

With the view of obtaining some further evidence on the subject, the behaviour of phenyl isopropyl ketone towards such reagents has been investigated, as it was thought possible that this ketone might react with certain carboxylic acids in accordance with the following scheme (compare 1 (b), *loc. cit.*, p. 34):

yielding ethyl benzoate and a new ketone.

The ketone used in the first experiment was prepared from isobutyl chloride and benzene by the Friedel Crafts' reaction, and the acid chloride itself from a sample of calcium isobutyrate. When this ketone, after careful fractionation, was brought into contact with sodium and ethyl acetate, formate, benzoate, or oxalate, in ethereal solution, highly coloured liquids were produced, which, when shaken with water, yielded yellow aqueous extracts, from which acids precipitated small quantities of acidic oils. The latter gave violet or deep-brown colorations with ferric chloride, and, in general, deported themselves as β -diketones or β -ketonic esters.

Later the ketone was allowed to react with ethyl phthalate and sodium, as the ketonic compound, which would arise as the result of the above series of reactions, would then have had the structure (I), from which an acid could be obtained and easily identified,

even if formed in comparatively small quantities, by means of its characteristic oxime-anhydride (II).

A red solution was formed in the cold, and to this alcoholic potassium hydroxide was added, and the whole heated for several hours on the water-bath, the ether being allowed to escape; hydroxylamine hydrochloride was then added, when, on cooling, a small quantity of a compound separated, which was at first thought to be the expected oxime-anhydride. It was collected, crystallised from alcohol, and analysed:

0.1996 gave 0.5009 CO_2 and 0.0921 H_2O . $\text{C} = 68.3$; $\text{H} = 5.2$.

$\text{C}_{10}\text{H}_9\text{O}_2\text{N}$ requires $\text{C} = 68.0$; $\text{H} = 5.1$ per cent.

It thus had the composition of *ethylidenephthalideoxime*,

and melted at 111° ; its identity with that compound was established by preparing a sample of the latter from synthetical ethyldene-phthalide and hydroxylamine; the compounds were identical in all respects, and mixtures melted at the same temperature as either separately.

The formation of this substance in the above reaction suggested that the original ketone contained phenyl ethyl ketone, owing to the unsuspected presence of propionate in the sample of calcium isobutyrate. Repeated fractionation of the ketone did not serve appreciably to diminish its reactivity towards esters and sodium, and the whole was therefore converted into oxime, the latter carefully purified, and reconverted into ketone by the processes described below. When purified in this way, the ketone displayed complete indifference towards carboxylic esters (including ethyl phthalate) in presence of sodium even at the temperature of the water-bath; that is to say, no trace of ketonic compound other than the original one could be detected.

It must be concluded, therefore, either that phenyl isopropyl ketone does not react at all with carboxylic esters in the presence of sodium or sodium ethoxide, or that the product decomposes exclusively into its original generators. It would be interesting to ascertain whether diisopropyl ketone would react with ethyl phthalate and sodium yielding isopropylidenephthalide and ethyl isobutyrate, but this the authors have not had the opportunity to test.

Preparation of Ketoximes and their Use in the Purification of Ketones.

Phenyl isoPropyl Ketoxime.

Some five years ago the authors devised the following process for preparing oximes, and using these for the purification of ketones; as the methods have proved to be of very general applicability, the more important details may be given here.

In preparing oximes the main practical advance consisted in avoiding the use of water other than that possibly contained in the solvent alcohol; the quantity of solvent then necessary is, as a rule, greatly diminished, whilst the use of sodium acetate precludes the possibility of any appreciable hydrolysis or transformation of the oximo formed.

The ketone is dissolved in at least three times its weight of spirit of 94–100 per cent. strength, the quantity and percentage of solvent depending mainly on the solubility of the ketone in the boiling solvent. To the hot solution is added 1 to $1\frac{1}{2}$ molecular proportions of solid hydroxylamine hydrochloride, and then at once excess of anhydrous sodium acetate; sodium chloride separates, but the whole is heated (at a temperature somewhat below that likely to cause bumping) until a drop of the solution, added to about 1 c.c. of 10 per cent. sodium hydroxide, gives a clear solution

with no odour of ketone. The whole is cooled, evaporated, if necessary, in cases where the ketone is sparingly soluble, and the bulk of solvent therefore considerable, mixed with water, and the oxime removed by filtration or by extraction with light petroleum or ether. Nearly quantitative yields have been obtained with most simple ketones experimented with, and such compounds as camphor-oxime are prepared much more easily and economically by this process than by those usually recommended. Crossley and Renouf found that a modification of this method gave good results with dimethyldihydroresorcin (compare *Trans.*, 1909, **95**, 930, *footnote*), and it might with great advantage replace the older methods in nearly all cases.

The regeneration of the ketone from the pure oxime is accomplished most satisfactorily as follows. The oxime is heated for several hours on the water-bath with 3 to 4 parts by weight of 15 per cent. hydrochloric acid, and $\frac{1}{2}$ to $\frac{3}{4}$ part by weight of commercial formaldehyde (40 per cent.); the whole is cooled, poured into twice its bulk of water, extracted with ether, and the latter washed repeatedly with water, dried, and evaporated, and the residue purified by fractional distillation. The yields are from 85 to 95 per cent. of those theoretically possible in all cases tried, with the exception of oximes, such as that of camphor, which are very prone to undergo the Beckmann transformation.

Phenyl isopropyl ketone, purified in this manner, boiled at 217° , and had D_{20}^{25} 0.9886 (two specimens). (Found, $C=81.1$; $H=8.2$. Calc., $C=81.1$; $H=8.1$ per cent.)

The semicarbazone crystallised from alcohol in needles, melting at 181° :

0.1985 gave 0.4711 CO_2 and 0.1310 H_2O . $C=64.7$; $H=7.3$.

$C_{11}H_{15}ON_3$ requires $C=64.4$; $H=7.3$ per cent.

The oxime, purified by repeated crystallisation from light petroleum, crystallises from that solvent in transparent, lustrous, massive tablets, melting sharply at 94° . (Found, $C=73.6$; $H=8.1$. Calc., $C=73.6$; $H=8.0$ per cent.)

Rattner (*Ber.*, 1887, **20**, 206) describes the oxime as forming leaflets, melting at 58° , and Claus (*J. pr. Chem.*, 1892, [ii], **46**, 480) gives 61° .

The present authors, suspecting the possibility of stereoisomerism, have prepared the oxime in neutral solutions, in alkaline solutions of various strengths, and at temperatures varying from 15° to 100° , but in all cases the only form obtained was that melting at 94° . The oxime was only obtained in small plates or leaflets when the original ketone was contaminated with phenyl ethyl ketone, and

possibly a similar cause contributed to the results of Rattner and of Claus.

Phenyl ethyl ketoxime was prepared, for comparison with the above oxime, from phenyl ethyl ketone obtained by the interaction of magnesium ethyl bromide and benzonitrile. It had all the properties assigned to it by Pampel and Schmidt (*Ber.*, 1886, **19**, 2896).

Action of Ethyl Nitrite on Phenyl isoPropyl Ketone in Presence of Sodium Ethoxide.

It has been shown that certain ketones which contain the complex $\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}<$ as part of a ring, although reacting at the $\cdot\text{CH}_2\cdot$ group when subjected to treatment with carboxylic esters in the presence of sodium ethoxide, are attacked by alkyl nitrites in similar circumstances at the $\cdot\text{CH}<$ group, ring scission taking place simultaneously probably in accordance with the following scheme (compare Clarke, Lapworth, and Wechsler, *Trans.*, 1908, **93**, 35):

No direct proof of the formation of ester was advanced at the time, and the reaction was not applied to any simple ketone. The following experiment confirming the above scheme was carried out by the present authors with highly purified phenyl isopropyl ketone.

Sodium (1.5 grams) was dissolved in about 25 c.c. of 99.5 per cent. alcohol, phenyl isopropyl ketone (10 grams) was then added, the whole being subsequently kept cold by means of ice-water while ethyl nitrite (5 grams) in strong spirit was slowly introduced. A white solid separated almost at once, and, at the end of two hours, was collected and identified as sodium benzoate (doubtless formed as above by the action of sodium hydroxide on the nitroxylated ketone forming the intermediate product of the reaction). The alcoholic mother liquor was diluted with water, the oil which separated being removed, washed, and dried; 2 grams of pure ethyl benzoate, boiling at 212° , were obtained by fractionation of this oil.

The alkaline mother liquor was acidified and extracted with ether, which was then washed with water, dried, and evaporated; the residue was a mixture which was fractionated by means of

light petroleum. From the more soluble portion acetoxime was readily separated and identified.

Some of the cost of this investigation was defrayed from a grant from the Government Grant Fund of the Royal Society, for which the authors desire to acknowledge their indebtedness.

CCXIII.—*Contributions to the Chemistry of the Terpenes. Part X. The Action of Chromyl Chloride, Nitrous Acid, and Nitric Acid on Bornylene.*

By GEORGE GERALD HENDERSON and ISIDOR MORRIS HELLBRON.

UP to the present time few of the derivatives of bornylene have been prepared, although the interesting relationship of this terpene to camphene, borneol, and camphor renders the full investigation of its chemical character desirable. We have accordingly begun to study these compounds, and the present paper contains an account of the results obtained by oxidising bornylene with chromyl chloride, and by attacking it with nitrous and nitric acids respectively.

Bredt and Jagelki (*Annalen*, 1900, **310**, 112) observed that camphene, on treatment with chromyl chloride, yields an additive product which reacts with water, giving as sole product camphenilanaldehyde, $C_9H_{15}\cdot CHO$. Camphenilanic acid, $C_9H_{15}\cdot CO_2H$, which is produced by spontaneous oxidation of the aldehyde, is transformed into the stereoisomeric *isocamphenilanic acid* when heated with concentrated nitric acid. Our experiments show that if bornylene is subjected to the action of chromyl chloride dissolved in carbon disulphide, it also yields a solid *additive product*, $C_{10}H_{16}\cdot 2CrO_2Cl_2$, which reacts easily with water, but, unlike the corresponding camphene compound, gives two products. One of these, a saturated *chloro-ketone*, $C_{10}H_{15}OCl$, which constitutes about 65 per cent. of the whole, is apparently a derivative of camphor; the other is camphenilanaldehyde, a substance which has already been prepared from camphene in several different ways, and of which the formation from bornylene is of great interest. The aldehyde is probably mixed with a little *isocamphenilanaldehyde*, which has been obtained from camphene in a different manner (Henderson and Sutherland, this vol., p. 1539), because the acid

formed by its spontaneous oxidation in the air appears to contain a small proportion of *isocamphenilanic* acid. If, as is probable, *camphenilanaldehyde* has the formula given below (III), its formation from *bornylene* (I) must involve a certain rearrangement of the latter's molecular structure. Possibly an unstable oxide (II) is produced by the action of water on the additive compound, and at once changes to the aldehyde:

It is most probable that *camphenilanic* and *isocamphenilanic* acids are stereoisomerides, and, as Bredt and Jagelki have shown, the *iso*-acid is produced when the other is subjected to prolonged heating with nitric acid, or when *camphenilanaldehyde* is oxidised with potassium permanganate. We have found that repeated slow crystallisations from such solvents as water, alcohol, and light petroleum likewise bring about the conversion of the one form into the other, although the process is tedious and incomplete; quite a number of different mixtures of the two acids which have constant melting points can be obtained by rapid crystallisation. From acetic acid, on the other hand, *camphenilanic* acid can be crystallised several times with little or no formation of the *iso*-acid. We have also observed that on treatment with semicarbazide hydrochloride and potassium acetate in the usual manner, *camphenilanaldehyde* yields the semicarbazone of *isocamphenilanaldehyde*, which, when liberated by the action of dilute acids, is converted into the *iso*-acid on exposure to the air.

For comparison with *bromocamphenilanic* acid, we prepared *bromoisocamphenilanic* acid, $\text{C}_9\text{H}_{14}\text{Br}\cdot\text{CO}_2\text{H}$, by converting the *iso*-acid into its *chloride*, $\text{C}_9\text{H}_{13}\cdot\text{COCl}$, heating this compound with bromine under pressure at about 60° , and decomposing the product, the *chloride* of *bromoisocamphenilanic* acid, $\text{C}_9\text{H}_{14}\text{Br}\cdot\text{COCl}$, with water. If the bromination of the *chloride* is carried out at a higher temperature, a crystalline neutral compound, which appears to have the formula $\text{C}_{10}\text{H}_{15}\text{OBr}$, is produced along with the *hromo*-acid. On one occasion we used *isocamphenilanic* acid mixed with a considerable proportion of *camphenilanic* acid, in the expectation of obtaining a mixture of the *bromo*-acids which might be more easily separated than the parent substances. The sole product, however, was *hromoisocamphenilanic* acid, and it is evident that during the process the *chloride* of *camphenilanic* or of *bromocamphenilanic* acid must have undergone conversion into the corresponding derivative of *isocamphenilanic* acid.

When heated with aqueous sodium carbonate, bromocamphenilanic acid yields the α -hydroxy-acid, camphenylic acid,

but bromocamphenilanic acid behaves quite differently, being converted into an unsaturated acid, $\text{C}_9\text{H}_{13}\cdot\text{CO}_2\text{H}$.

The chloro-ketone, $\text{C}_{10}\text{H}_{15}\text{OCl}$, forms a *semicarbazone*, which melts and decomposes at $234\text{--}235^\circ$. The chlorine in the ketone is not easily displaced, but on heating the compound with concentrated alcoholic potassium hydroxide under pressure at 160° it is converted into camphor, and it is slowly oxidised to camphoric acid by treatment with an alkaline solution of potassium permanganate. The compound, therefore, is a *chlorocamphor*, and possibly is

stereoisomeric with 3-chlorocamphor, which melts at $93\text{--}94^\circ$.

The formation of camphenilanaldehyde, a derivative of camphene, from bornylene is of considerable importance, as indicating that there is great similarity between the nuclei of these terpenes. The results of the investigation of other derivatives of these terpenes, which we hope to be able to communicate to the Society before long, appear to support this view.

Results which are of importance as regards the question of its constitution have been obtained by subjecting camphene to the action of nitrous and nitric acids, and it therefore appeared of interest to investigate the behaviour of bornylene when attacked by these reagents. From camphene, by treatment with nitrous acid, Jagelki (*Ber.*, 1899, **32**, 1493) obtained a crystalline nitro-nitrosite, $\text{C}_{10}\text{H}_{15}(\text{NO}_2)(\text{N}_2\text{O}_3)$, and an oily *isonitrosite*, $\text{C}_{10}\text{H}_{15}(\text{N}_2\text{O}_3)$, which was readily decomposed, yielding the so-called camphenil nitrite, $\text{C}_{10}\text{H}_{15}\cdot\text{NO}_2$; the latter compound was easily converted into camphenilanaldehyde, $\text{C}_{10}\text{H}_{16}\text{O}$, and camphenilone, $\text{C}_9\text{H}_{14}\text{O}$, respectively. When treated in a similar manner with nitrous acid, bornylene has been found to yield several different compounds, some of which differ essentially in character from the derivatives obtained from camphene. The chief product was a crystalline *nitrosite*, $\text{C}_{10}\text{H}_{16}(\text{N}_2\text{O}_3)$, which proved to be bimolecular, and evidently has the same nucleus as bornylene, because it yields camphoric acid on oxidation:

Another product was a viscous liquid of a green colour, which

owing to its extreme instability could not be purified sufficiently for analysis. It is very similar in properties to the isonitrosite prepared from camphene, for example, in its solubility in aqueous solutions of alkali hydroxides, and in all probability is the corresponding

In addition to the above, we found among the products of the reaction a considerable quantity of a crystalline solid, melting at 198° , which was proved to be camphorquinone, and a very small amount of a colourless, crystalline compound, which melted at $84-85^\circ$. This substance contains nitrogen, but the quantity in our hands was too small to permit of its identification.

On oxidising camphene with nitric acid, Marsh and Gardner (Trans., 1891, 59, 648; 1896, 69, 74) obtained the tribasic cam-

ene was oxidised in a similar manner, we found, as was to be expected, that the chief product was camphoric acid. Along with this there separated from the mixture of oxidation products a yellow, crystalline compound, which melts at 137° , and volatilises in a current of steam. This compound proved to be a dinitrocamphane, $\text{C}_{10}\text{H}_{16}(\text{NO}_2)_2$, and its formation must be due to the addition of nitric peroxide, produced by reduction of the nitric acid, to some of the bornylene. On oxidation with dilute alkaline permanganate, it is readily converted into camphoric acid:

On reduction with sodium and alcohol, or with tin and hydrochloric acid, this dinitrocamphane is completely decomposed, but alcoholic ammonium sulphide converts it into a yellow, crystalline substance, which is apparently not an amino-derivative, but possibly a mononitrocamphane.

Besides these substances the mixture of products was found to contain a very small quantity of a colourless, crystalline compound, which melts at about 174° . This compound, which contains nitrogen, is neutral in character.

Our results show that neither nitrous nor nitric acid, when used under the conditions described below, tends to bring about any

rearrangement of the nucleus of bornylene, for the products are all typical derivatives of that hydrocarbon, and not of camphene.

We are at present engaged in studying other derivatives of bornylene, and shall submit our results to the Society before long.

EXPERIMENTAL.

The Oxidation of Bornylene with Chromyl Chloride.

Preparation and Oxidation of Bornylene.—Bornylene was prepared from borneol, through bornyl methyl xanthate, essentially according to the method of Tschugaeff (*Ber.*, 1899, **32**, 3332), but with modifications which experience has shown to be of value. In the first stage of the process the best results were obtained by boiling a solution of 200 grams of borneol in 250 grams of dry toluene with the necessary quantity of sodium. The heating of the liquid was effected by means of a glycerol bath, because when a sand-tray is used, local overheating and consequent charring through decomposition of the material are apt to occur, and there is considerable risk of the flask breaking.

A 10 per cent. solution of 100 grams of chromyl chloride (2 mols.) in dry carbon disulphide was slowly added, in small portions, to a well-cooled solution of 41 grams of bornylene (1 mol.) in the same solvent and of similar concentration, with thorough agitation after each addition. The reaction proceeded smoothly, with evolution of heat, and a dark brown precipitate slowly settled, and was then collected, washed with carbon disulphide, and transferred to wide-mouthed bottles while still in the form of a pasty mixture with some of the solvent. The mass was added, in small quantities at a time, to ice-cold water containing a little sulphurous acid, and the mixture vigorously shaken after each addition until the solid was completely decomposed, with the result that an oily substance separated from the aqueous solution. The oxidation product was extracted by repeated agitation of the mixture with carbon disulphide, and the extract was well washed with water, dried with calcium chloride, and heated to expel the carbon disulphide. The yield is very good, little or no resinification taking place.

•The *additive compound*, $C_{10}H_{16} \cdot 2CrO_2Cl_2$, thus obtained from bornylene is, when in the dry state, a light brown powder. It is extremely hygroscopic, and decomposes on exposure to moist air, forming a dark green liquid with a sweet odour.

Separation and Identification of Camphenylanaldehyde.—The oily liquid obtained from the additive product was well mixed with a saturated solution of sodium hydrogen sulphite, with the result that after some time a crystalline "bisulphite compound" separated in

very small, colourless plates. Ether was added in order to extract the substance which had not reacted with the bisulphite, and the ethereal solution was separated and treated with fresh quantities of the reagent until no more of the bisulphite compound was formed. The crystals were collected, and washed with alcohol and with ether, and the aqueous filtrate was extracted with ether, this ethereal solution being added to the first. The bisulphite compound was mixed with aqueous sodium carbonate, and heated with steam, and the aldehyde which solidified in the receiver was collected, quickly dried by pressure in porous paper, and distilled in an atmosphere of dry carbon dioxide. In this way the aldehyde was obtained in colourless crystals, with a strong odour. It melted at $71-72^{\circ}$, boiled at $192-193^{\circ}$ under atmospheric pressure, and was quickly oxidised on exposure to the air. Its semicarbazone was prepared, and purified by crystallisation from methyl alcohol, from which it separated in lustrous, pearly leaflets, with the melting point $191-192^{\circ}$. (Found, C=63.1; H=9.1; N=20.3. Calc., (C=63.1; H=9.1; N=20.1 per cent.)

As the properties of this aldehyde from bornylene appeared to be identical with those of Brett's camphenilanaldehyde, we prepared a quantity of the latter from camphene for purposes of comparison, and converted some of it into its semicarbazone. (Found, N=20.2.)

This semicarbazone melted at the same temperature as that prepared from the aldehyde obtained from bornylene, and the melting point remained unaltered when the two compounds were mixed. In short, bornylene, when oxidised with chromyl chloride, yields the same aldehyde as camphene does when similarly treated.

We observed also that the semicarbazones prepared from camphenilau- and isocamphenilau-aldehydes, as also a mixture of the two, have the same melting point. To clear up this point we decomposed some of the semicarbazone prepared from camphenilau-aldehyde by warming it with the calculated quantity of dilute sulphuric acid, and found that the liberated aldehyde was wholly oxidised to isocamphenilanic acid on exposure to the air. Hence it appears that the product of the action of semicarbazide hydrochloride on camphenilanaldehyde is the semicarbazone of isocamphenilanaldehyde—a result which is not surprising, because the two aldehydes are almost certainly stereoisomerides.

Camphenilanic and isoCamphenilanic Acids.—The aldehyde obtained from bornylene was exposed to the air for some time, and, after oxidation appeared to be complete, the acid formed was separated from any unchanged aldehyde by means of aqueous sodium carbonate. Acidification of the alkaline solution produced an oily precipitate, which soon solidified, and was then collected,

washed with water, and dried. A melting-point determination showed that, whilst the bulk of the product was camphenilanic acid, a small proportion of an acid of higher melting point was also present. By fractional crystallisation from somewhat diluted acetic acid the camphenilanic acid was obtained in crystals melting at 65° ; the other acid separated from light petroleum or from dilute alcohol in colourless prisms, which melted at 118° , and in all other respects was exactly similar to isocamphenilanic acid. Analysis established its identity. (Found, $C=71.6$; $H=9.3$. Calc., $C=71.4$; $H=9.5$ per cent.)

Having accumulated a quantity of camphenilanic acid, we endeavoured to convert it into its isomeride by crystallisation from different solvents, and found that when repeatedly crystallised from water, alcohol, or light petroleum, camphenilanic acid is gradually transformed into isocamphenilanic acid. For example, a specimen of the former acid which melted at 65° , after one crystallisation from water melted at 70° , and after a second at 86° . The process is tedious and unsatisfactory owing to the tendency of the two acids to form mixtures of constant melting point, and the consequent difficulty in separating them. *iso*Camphenilanic acid is not formed when camphenilanic acid is crystallised from glacial acetic acid, or heated at a temperature above its melting point for several days, or exposed to ultra-violet light. Bredt showed that the *iso*-acid is produced when camphenilanic acid is boiled with concentrated nitric acid, but according to our experience some of the latter remains unaltered, even when the heating is prolonged for a fortnight. A mixture of the two acids was also obtained when camphenilaldehyde was oxidised with an alkaline solution of potassium permanganate. A comparatively simple method of obtaining isocamphenilanic acid is to convert camphenilaldehyde into the semicarbazone, to decompose this compound with dilute acids, and to allow the isocamphenilaldehyde thus produced to undergo oxidation in the air.

Preparation of Bromoisocamphenilanic Acid and of the Unsaturated Acid $C_9H_{13}CO_2H$.—The chloride of isocamphenilanic acid, $C_9H_{13}COCl$, was prepared by adding the acid in small portions to a mixture of the calculated quantity of phosphorus pentachloride with light petroleum, heating under a reflux condenser until the reaction was completed, and finally distilling fractionally under diminished pressure. The chloride is a colourless, oily liquid, with a not unpleasant odour, which boils at $118^{\circ}/25$ mm., and rapidly decomposes in moist air, with formation of isocamphenilanic acid. By heating in a sealed tube for several hours at about 60° with a slight excess of bromine it was converted into the chloride of bromo-

isocamphenilanic acid, $C_9H_{11}Br \cdot COCl$, which is also a heavy, viscous liquid, and is decomposed by water, giving *bromoisocamphenilanic acid*, $C_9H_{11}Br \cdot CO_2H$. The chloride was poured into water, and the mixture well stirred until the oily chloride was completely converted into the crystalline acid, which was collected, washed with water, and purified by recrystallisation, first from dilute methyl alcohol, and finally from light petroleum. The acid forms small, colourless prisms, which melt at $204-205^\circ$. It is readily soluble in alcohol, ether, or light petroleum, but almost insoluble in water:

0.2022 gave 0.1550 AgBr. $Br = 32.6$.

$C_{10}H_{13}O_2Br$ requires $Br = 32.3$ per cent.

In the first preparation of bromoisocamphenilanyl chloride the mixture was heated in a sealed tube at 100° for about twenty-four hours. On treatment of the product with water, a mixture of bromoisocamphenilanic acid with a considerable proportion of a neutral compound, $C_{10}H_{15}OBr$, was obtained. This substance crystallises from methyl alcohol in minute, colourless needles, which melt at 182° . It is sparingly soluble in methyl alcohol, readily so in ether or light petroleum, and insoluble in water and in aqueous solutions of sodium carbonate or sodium hydroxide:

0.2076 gave 0.1687 AgBr. $Br = 34.6$.

$C_{10}H_{15}OBr$ requires $Br = 34.6$ per cent.

With the object of preparing the corresponding hydroxy-derivative, bromoisocamphenilanic acid was warmed for about three hours on the water-bath with aqueous sodium carbonate. From the solution, on cooling, a rather sparingly soluble sodium salt crystallised out. The salt was dissolved in water and decomposed by addition of dilute sulphuric acid, and the precipitated acid was purified by crystallisation from dilute methyl alcohol. Examination of this substance proved it to be, not the expected hydroxy-acid, but an unsaturated acid of the formula $C_9H_{13} \cdot CO_2H$. It crystallises in fine, lustrous plates, melts at 147° , is readily soluble in alcohol or ether, but insoluble in water, and volatilises in a current of steam. It immediately reduces an alkaline solution of potassium permanganate in the cold:

0.1855 gave 0.4878 CO_2 and 0.1480 H_2O . $C = 71.7$; $H = 8.8$.

$C_{10}H_{14}O_2$ requires $C = 72.2$; $H = 8.4$ per cent.

The sodium salt, $C_9H_{13} \cdot CO_2Na$, separates from water, in which it is not very readily soluble, in beautiful, silky plates.

Separation of the Chloro-ketone, $C_{10}H_{15}OCl$.—The ethereal solution of the oxidation product, from which the aldehyde had been removed by treatment with sodium hydrogen sulphite, was washed successively with aqueous sodium carbonate and with water, and

dried. The ether was removed by distillation, the residue heated in a current of steam, and the yellow solid, which condensed in the receiver, collected and pressed on a porous plate to remove traces of oily matter. Purification of this substance by crystallisation was difficult, owing to its great solubility in all the usual organic solvents, and the method finally adopted was repeated fractional precipitation with water from a solution in glacial acetic acid. Once partly purified in this way the substance can be crystallised from dilute alcohol. When pure it forms minute, colourless crystals, which melt sharply at 165° , and have a faint, pleasant odour. It is extremely volatile in steam, but decomposes on distillation, even under diminished pressure. Its solubility in organic solvents is very great, but it is insoluble in water. It has the character of a saturated ketone, readily forming a semicarbazone, but resisting oxidation:

0.2218 gave 0.5230 CO_2 and 0.1610 H_2O . $\text{C}=61.3$; $\text{H}=8.1$.

0.1636 „ 0.1256 AgCl . $\text{Cl}=19.0$.

$\text{C}_{10}\text{H}_{15}\text{OCl}$ requires $\text{C}=61.3$; $\text{H}=8.1$; $\text{Cl}=19.0$ per cent.

The semicarbazone of the chloro-ketone,

which was prepared in the usual way, crystallises from dilute alcohol in small, colourless prisms. It is fairly readily soluble in alcohol, and melts at $234-235^{\circ}$, beginning to decompose a little below this temperature:

0.1850 gave 28.6 c.c. N_2 (moist) at 14° and 758 mm. $\text{N}=18.2$.

$\text{C}_{11}\text{H}_{18}\text{ON}_3\text{Cl}$ requires $\text{N}=17.3$ per cent.

The chloro-ketone was found to be slowly oxidised by potassium permanganate in alkaline solution. After heating on the water-bath for two days, the excess of permanganate was reduced with sulphurous acid, the precipitated manganese dioxide removed by filtration, and the filtrate concentrated to small bulk. On addition of dilute sulphuric acid a crystalline acid was obtained, and was collected and recrystallised from hot water. The purified acid melted at 187° , and in other respects resembled camphoric acid. Its identity was established by heating it at a temperature above its melting point in a current of carbon dioxide, distilling the product, and recrystallising the distillate from alcohol. The crystals melted sharply at 221° , the melting point of camphoric anhydride.

The removal of chlorine from the ketone was difficult, and attempts to effect this by heating it with silver oxide in alcoholic solution and by treatment with sodium and alcohol proved fruitless. The end was attained by heating 5 grams of the ketone with a concentrated alcoholic solution of 2 grams of potassium hydroxide in a sealed tube for seven hours at $150-160^{\circ}$. The alcoholic

solution was mixed with water and agitated several times with ether, and the ethereal extract was washed with water, dried, and distilled to remove the ether. The residue was heated in a current of steam, and a crystalline solid separated from the distillate, which in all respects was indistinguishable from camphor. The solid was converted into a semicarbazone, which after crystallisation from methyl alcohol melted at 236° , the melting point of camphorsemicarbazone, and from which, by treatment with dilute sulphuric acid, a specimen of camphor, melting at 174° , was regenerated.

From these results it is evident that the chloro-ketone is a *chloro-camphor*, different from any hitherto described.

The Action of Nitrous Acid on Bornylene.

Preparation of the Nitrosite.—Glacial acetic acid was added very slowly, in small quantities at a time, to a concentrated aqueous solution of 100 grams of sodium nitrite, on which rested a concentrated solution of 100 grams of bornylene in light petroleum. The mixture was gently warmed on the water-bath under a reflux condenser, with occasional agitation, for about an hour, and then left for twenty-four hours at the ordinary temperature. During this time crystals of the nitrosite slowly separated at the surface of the aqueous layer, the light petroleum acquiring, first a blue, then an intense green, and finally, at the end of the reaction, a yellow coloration. The petroleum solution was removed, and repeatedly treated in the same manner with fresh quantities of sodium nitrite and acetic acid until the odour of bornylene had disappeared. This method gave better results than prolonged treatment of bornylene with nitrous acid in one operation. The crystals of the nitrosite were separated from the aqueous solution by filtration through glass wool, thoroughly washed with water, alcohol, and ether successively, and purified by crystallisation from acetone. From this solvent the nitrosite separates in beautiful, silky needles, which, when quickly heated, melt sharply at 163° , forming a bluish-green liquid, which decomposes with violent gas evolution. It is readily soluble in acetone, glacial acetic acid, benzene, or chloroform, but very sparingly so in alcohol or ether, and is insoluble in water or aqueous solutions of alkali hydroxides or hydrochloric acid. The solutions have a characteristic blue colour. The nitrosite is not decomposed by alkali hydroxides or concentrated hydrochloric acid, even when heated:

0.2044 gave 0.4176 CO_2 and 0.1470 H_2O . C=55.7; H=8.0.

0.2055 " 24 c.c. N_2 (moist) at 13.2° and 740 mm. N=13.4.

$\text{C}_{10}\text{H}_{16}\text{O}_3\text{N}_2$ requires C=56.6; H=7.5; N=13.2 per cent.

Determinations of the molecular weight by the ebullioscopic method in acetone solution gave the following results:

Substance (gram).	Solvent (grams).	E.	M. W.
0.2196	17.47	0.05°	432
0.4291	17.47	0.118°	358
0.6495	17.47	0.185°	346

$C_{10}H_{14}O_3N_2$ requires M. W. = 212.

These results indicate that the substance is bimolecular, the fall in the molecular weight in the later determinations being possibly due to a slight decomposition of the complex molecule on continued heating of the solution. The bimolecular form may be represented thus:

The nitrosite, on oxidation with a warm dilute alkaline solution of potassium permanganate, yields an acid, which melts at 187° , and in all other respects is identical with camphoric acid.

Separation of the iso-Nitrosite.—The light petroleum, from which the nitrosite had separated, was repeatedly agitated with concentrated aqueous potassium hydroxide until nothing more passed into solution, and the red alkaline liquid was diluted with water and acidified with hydrochloric acid, care being taken to keep the mixture cool. The liquid was repeatedly agitated with ether, the ethereal extract washed with water and dried, and, after removal of the ether by distillation, the *isonitrosite* was obtained as a viscid, oily liquid, with a green colour and a pleasant odour. It is an extremely unstable substance, decomposing with violent evolution of gas when heated, even under greatly diminished pressure. It dissolves in aqueous solutions of alkali hydroxides, and the alkali derivatives are extremely readily soluble in all solvents. A small quantity of the *potassium* salt, probably $C_{10}H_{15}N_2O_3K$, was obtained as an orange-coloured powder by the action of potassium ethoxide on a solution of the *isonitrosite* in dry benzene. Attempts to prepare products of hydrolysis and of reduction of the *isonitrosite* were unsuccessful, as in each case the substance was apparently completely decomposed; yet its close resemblance to the corresponding *isonitrosite* prepared from camphene lends probability to the conclusion that this compound is bornylene *isonitrosite*.

Separation of Camphorquinone.—After extraction of the *isonitrosite* by aqueous potassium hydroxide, the petroleum solution was well washed with water, dried, and, after removal of the light petroleum by distillation, the residual yellow oil was fractionated

under diminished pressure. The most volatile fraction consisted of some bornylene which had escaped attack, and the second fraction, which was small in quantity, had a strong odour of camphor; the last fraction, which had a deep yellow colour, deposited some crystals on keeping. After removal of these crystals, the yellow, oily liquid which remained was placed in the ice-chest, when it gradually solidified, and after purification by crystallisation from light petroleum was obtained in delicate needles, of a deep yellow colour and with a strong odour, which melted sharply at $197-198^{\circ}$. It is readily soluble in organic solvents, and sparingly so in hot water; it volatilises very easily in a current of steam, and sublimes readily at a low temperature. In all these respects it is identical with camphorquinone. The aqueous solution, from which the crystals of nitrosite had been separated by filtration, had a deep yellow colour, and also yielded some camphorquinone.

The crystalline solid, which separated from the distillate of crude camphorquinone, melted at $70-80^{\circ}$, and was evidently a mixture of the latter with some other substance. By repeated crystallisation of this mixture from methyl alcohol this compound was obtained in colourless prisms, which melted at $84-85^{\circ}$. It is sparingly soluble in water, and readily so in organic solvents. Analysis gave results which indicated that the substance might be bornylene nitrite, but we were unable, from lack of material, to confirm this. On treatment with alkali it yields a substance which resembles camphor:

0.1934 gave 0.4866 CO_2 and 0.1774 H_2O . $\text{C}=66.9$; $\text{H}=9.9$.

0.1472 „ 9.95 c.c. N_2 (moist) at 24° and 777 mm. $\text{N}=7.7$.

$\text{C}_{10}\text{H}_{15}\text{O}_2\text{N}$ requires $\text{C}=66.2$; $\text{H}=8.3$; $\text{N}=7.7$ per cent.

The Action of Nitric Acid on Bornylene.

Separation of Dinitrocamphane.—Forty grams of bornylene were warmed on the water-bath under a reflux condenser with about 500 c.c. of 30 per cent. nitric acid. Vigorous action took place, nitrous fumes being evolved in quantity, whilst owing to the heat of the reaction some of the unattacked bornylene volatilised into the tube of the condenser. After about an hour, when the first action had ceased, the flask and its contents were allowed to cool, and a further quantity of 270 c.c. of nitric acid (D 1.4) was added very gradually in small portions at a time. Care must be taken at this stage, for if too much of the strong acid was added at once oxidation took place with almost explosive violence. During this part of the process the bornylene which had volatilised was attacked by the nitric acid and the nitrous fumes, and washed back

into the flask. After all visible action had ceased, the solution was boiled in order to expel nitrous fumes, and left for twelve hours at the ordinary temperature, when a mass of crystals was deposited. The crystals were separated from the strongly acid liquid by filtration through glass wool, well washed with water, and dried in porous paper. Inspection revealed the presence of two substances in the product, some of the crystals being yellow and others colourless. The colourless crystals were found to be soluble in aqueous sodium carbonate, and therefore the mixture was warmed with excess of this reagent and the alkaline solution repeatedly shaken with ether, in which the yellow substance dissolved. The ethereal solution was washed with water, dried, and, after removal of the ether by distillation, a yellow, oily substance was obtained, which became crystalline on keeping. After purification by crystallisation from methyl alcohol, this substance, 1:2-dinitrocamphane, had the form of long, slender, pale yellow needles, which melted at 137° without any signs of decomposition. It is readily soluble in ether or chloroform, moderately so in methyl or ethyl alcohol, and insoluble in water or acids. It dissolves to a small extent in hot solutions of the alkali hydroxides, imparting a deep yellow colour to the liquid. It volatilises slowly in a current of steam. Towards bromine or potassium permanganate the compound is inactive, being evidently saturated. The yield was about 5 per cent. of the bornylene taken. Analysis showed that it had the composition of a dinitrocamphane:

0.2033 gave 0.3916 CO_2 and 0.1320 H_2O . $\text{C}=52.6$; $\text{H}=7.2$.

0.2363 .. 26.4 c.c. N_2 (moist) at 16° and 737 mm. $\text{N}=12.4$.

$\text{C}_{10}\text{H}_{16}\text{O}_4\text{N}_2$ requires $\text{C}=52.6$; $\text{H}=7.0$; $\text{N}=12.3$ per cent.

When warmed with a dilute alkaline solution of potassium permanganate, the yellow crystals of the dinitrocamphane were gradually oxidised, and passed into solution. After the oxidation was completed, the precipitated manganese dioxide was removed by filtration, the filtrate acidified, and the acid which separated collected and crystallised from boiling water. It then melted at 187° , and was proved to be camphoric acid by conversion into camphoric anhydride, melting at 221° .

The ready oxidation of the substance to camphoric acid, and the results of analysis, prove that it has the bornylene or camphane structure, and is in all probability a dinitrocamphane, but attempts to prepare the corresponding diamino-derivative were unsuccessful. When sodium and alcohol or tin and hydrochloric acid were used as the reducing agent, complete disintegration of the molecule took place, gaseous fatty amines being evolved, and no definite product was obtained. Reduction with ammonium sulphide, on the other

hand, yielded a well-characterised compound. The dinitrocamphane was dissolved in alcohol, the necessary quantity of a concentrated solution of ammonia added, and hydrogen sulphide passed into the solution for some time. During this operation the liquid, previously almost colourless, acquired a dark red colour. The solution was then boiled for half an hour, filtered to remove precipitated sulphur, and left to cool, when crystals of a deep yellow colour separated. After recrystallisation from alcohol, the new compound was obtained in minute, hard prisms of a canary-yellow colour, which melt at $196-198^{\circ}$. It is only sparingly soluble in alcohol, and insoluble in water, but dissolves readily in ether. The quantity at our disposal only permitted of a nitrogen estimation. The result suggested that the new compound may be a mononitrocamphane, but it remains to be proved whether or not this is the case:

0.2026 gave 13.5 c.c. N_2 (moist) at 19° and 763 mm. $N = 7.7$.

$C_{10}H_{17}O_2N$ requires $N = 7.6$ per cent.

Separation of Camphoric Acid.—As already stated, colourless crystals of an acid separated along with the dinitrocamphane from the acid solution in which the bornylene had been oxidised, and were removed by treatment of the mixture with aqueous sodium carbonate. A further quantity was obtained from the acid mother liquor, which was subjected to steam distillation in order to remove a little dinitrocamphane which remained in solution, rendered alkaline by addition of excess of sodium carbonate, and agitated with ether, which dissolved a little of a substance which separated when the acid was neutralised. The mixed alkaline solutions were concentrated, and on acidification yielded a large quantity of an acid. After recrystallisation from water the acid melted at 187° , and its identity with camphoric acid was proved by analysis. (Found, $C = 60.2$; $H = 8.1$. Calc., $C = 60.0$; $H = 8.0$ per cent.)

The ethereal solution of the substance extracted from the alkaline liquid was washed and dried, and after removal of the ether a viscous, oily substance remained. This was distilled under diminished pressure in an atmosphere of dry carbon dioxide; considerable decomposition took place, but a portion which distilled at $180-185^{\circ}/25$ mm. solidified on cooling to a yellow mass. After repeated crystallisation from light petroleum the compound was obtained in the form of minute, colourless needles, which melted at about 174° . It is very readily soluble in alcohol, ether, or acetone, somewhat sparingly so in light petroleum, and insoluble in water, alkalis, or dilute mineral acids. The yield of this compound is extremely small, and from several different preparations only enough for one analysis was obtained, according to which the compound contains $C = 71$, $H = 10$, and $N = 6.7$ per cent.

We take this opportunity of thanking Mr. D. S. Dawson, B.Sc., and Mr. William Caw for valuable assistance, and the Carnegie Trust for a grant in aid of the expense of this work.

CCXIV.—*The Constitution of Camphene.*

By GEORGE GERALD HENDERSON and ISIDOR MORRIS HEILBRON.

THERE is still room for difference of opinion regarding the constitution of camphene, but this at least is certain, that the formula originally assigned to this terpene by Bredt is in reality that of the closely related bornylene (I), as is shown by the formation of the latter from borneol (II) through bornyl methyl xanthate, and by the ease with which it is converted into camphoric acid by oxidation. There can also be little doubt that the nuclei of camphene and bornylene, although to a large extent similar in structure, differ from one another more widely than, for example, in the position of a double linking, because, among other reasons, it has been observed that, on reduction by the contact method of Sabatier and Senderens, bornylene readily yields camphane, whilst camphene is converted into a dihydro-derivative which is quite different from camphane (Henderson and Pollock, *Trans.*, 1910, 97, 1620). It is generally agreed that bornylene is the normal product from borneol, and therefore that the formation of camphene from this alcohol is attended by a certain structural rearrangement.

From camphene, by the action of chromyl chloride, Bredt and Jagelki (*Annalen*, 1900, 310, 112) obtained an additive compound which on treatment with water gave only one product, camphenilanaldehyde (V). From the corresponding acid an α -hydroxy-derivative, camphenylic acid (VI), was prepared, and from the latter, by oxidation, the ketone camphenilone (VII), which so closely resembles camphor both in physical and in physiological properties. By means of an entirely different oxidising agent, hydrogen peroxide, Henderson and Sutherland (this vol., p. 1539) recently obtained from camphene a mixture of oxidation products, the chief of which were *isocamphenilanaldehyde* (which is almost certainly a stereoisomeride of camphenilanaldehyde), camphenilone, and an acid, $C_{10}H_{16}O_2$, isomeric with *isocamphenilanoic acid*, into which it is transformed when heated with acetic anhydride. Camphene has also been converted into camphenilanaldehyde or camphenilone respec-

tively in other direct and simple ways; thus, when camphene nitrite (VIII) is hydrolysed, it yields the aldehyde, through rearrangement of the unsaturated alcohol (IX), which is the direct product of hydrolysis, while camphenilone is produced when the nitrite is treated with a dilute solution of potassium permanganate (Jagelki, *Ber.*, 1899, **32**, 1498). Further, in the course of an elaborate investigation of the products obtained by oxidising camphene with a dilute aqueous solution of potassium permanganate, Moycho and Zienkowski (*Annalen*, 1905, **340**, 17) prepared camphene glycol (IV) in considerable quantity, and showed that this compound must contain two hydroxyl groups, although it only yields a mono-benzoate, and that all its reactions point to the formula,

They found that camphenilanaldehyde was formed from the glycol under such conditions that no structural rearrangement would take place, and therefore that the linking of the carbon atoms in the two compounds is the same. Camphenylic acid and camphenilone were identified among the other products of the oxidation of the camphene, and were also prepared from the pure glycol by treatment with permanganate. Moycho and Zienkowski consider that their results prove conclusively the presence of the group >C:CH_2 in the molecule of camphene, and this view is supported by the observation of Balbiano and Paolini (*Ber.*, 1903, **36**, 3375) that camphene yields an additive compound when treated with aqueous mercuric acetate, whereas, according to these observers, the presence of a $\cdot\text{CH:CH}\cdot$ group would lead to the formation of an oxidation product.

The formation of camphenilanaldehyde from camphene by such different methods as those quoted, indicates that the central nucleus and the mode of attachment of the side groups in each of the two substances are identical. Definite proof of this has been given by Semmler (*Ber.*, 1909, **42**, 246, 962), who converted the aldehyde into an *enol*-acetate, reduced the latter to camphenilyl alcohol, prepared the corresponding chloride, and from this, by treatment with sodium and alcohol, regenerated camphene. It is also known that camphenilone has the same nucleus as camphene, for not only is it produced when the hydrocarbon is oxidised with potassium permanganate, or with hydrogen peroxide, or with moist ozone, but, in addition, the direct synthesis of camphene from camphenilone, through methylcamphenilol, has been effected by Moycho and Zienkowski (*Ber.*, 1905, **38**, 1061).

The formation and relationships of the derivatives mentioned above can be explained if the constitution of camphene be repre-

sented by the formula
$$\begin{array}{c} \text{CH}_2\text{·CH—CMe}_2 \\ | \quad | \\ \text{CH}_2 \quad | \\ | \quad | \\ \text{CH}_2\text{·CH—C·CH}_2 \end{array}$$
. This formula was suggested

by Wagner as the result of his study of the alcohols borneol and isoborneol, which, as corresponding with bornylene and camphene respectively, were believed to have quite different structures. But although borneol is a secondary, and isoborneol apparently a tertiary alcohol, it seems difficult to reconcile the view that their nuclei are entirely different with the facts that isoborneol on oxidation yields camphor, a ketone with the same nucleus as borneol, that under suitable conditions camphene can be obtained from borneol, and that isoborneol is converted into the sodium derivative of borneol when heated with sodium in xylene solution. If camphene had the constitution expressed in Wagner's formula, or in the

$$\begin{array}{c} \text{CH}_2\text{·CH—CMe}_2 \\ | \quad | \\ \text{CH}_2\text{·CH—CH} \end{array}$$
 formula
$$\begin{array}{c} \text{CH}_2 \quad \text{CH} \\ | \quad | \\ \text{CH}_2\text{·CH—CH} \end{array}$$
, which has been tentatively proposed by

Aschan in a recent paper (*Annalen*, 1910, 375, 336), its formation from borneol would involve a greater rearrangement of the molecule than seems probable from the facts already quoted, and, moreover, observations recently made in this laboratory (Henderson and Heibron, this vol., p. 1887) indicate that the molecular structure of camphene is closely related to that of bornylene. It has been found that, on treatment with chromyl chloride, bornylene gives an additive product, from which, by the action of water, excellent yields of two substances are obtained. One of these, a chloro-ketone of the formula $\text{C}_{10}\text{H}_{15}\text{OCl}$, appears to be a chlorocamphor, while the other is a derivative of camphene, being, in fact, camphenilaldehyde. If the formula of the aldehyde is that given below, the formation of this camphene derivative from bornylene can be easily understood, for it is only necessary to assume that when the additive compound reacts with water a substance of the type of an oxide is formed, which by a slight rearrangement passes into the aldehyde:

Such a rearrangement of the bornylene molecule is insignificant compared with that which would be involved if camphene were constituted as represented in the formulae of Wagner or of Aschan.

These results lead to the conclusion that as regards the greater part of their respective molecules, namely, the residue,

camphene and bornylene are identical. Support is given to this conclusion by the fact that camphene resembles bornyl chloride, which also contains this residue, in yielding camphor on oxidation with chromate mixture, and also, to a less extent, by the observation of Marsh and Gardner (Trans., 1891, 59, 648; 1896, 69, 74) that camphene is oxidised by moderately dilute nitric acid to camphoic (carboxyapocamphoric) acid, which on heating loses carbon dioxide and forms apocamphoric acid, which has been synthesised by Komppa (Ber., 1901, 34, 2472):

The relationship of all the derivatives of camphene, which have been mentioned above, to the present hydrocarbon and to each other can be stated very simply, as is shown in the scheme on p. 1905, on the assumption that camphene has the formula (III), which was originally proposed by Semmler, and which we consider to be the best expression of the known facts.

It must be noted that when camphene from isoborneol is oxidised with an alkaline solution of potassium permanganate, the chief product is the isomeride of camphoric acid, known as camphenecamphoric acid, and that some of this acid is also produced when nitric acid is used as the oxidising agent. It is known that camphenecamphoric acid is not an oxidation product of camphene glycol or of camphylic acid, but it has not yet been demonstrated that its constitution is different from that of camphoric acid. If it prove to be the case that these acids are differently constituted, and if at the same time it is assumed that camphenecamphoric acid has the same nucleus as camphene, the formation of this acid cannot be understood if either the formula given above (III) or Wagner's formula for camphene be adopted. The same difficulty arises in connexion with the acid, $\text{C}_{10}\text{H}_{16}\text{O}_2$, obtained by Henderson and Sutherland on oxidising camphene with hydrogen peroxide. There is no evidence, however, that the nuclei of camphene and of camphenecamphoric acid are identical. On the other hand, it is not at all improbable that camphene may undergo molecular rearrangement to some extent under the influence of such reagents as an alkaline

solution of potassium permanganate or hot nitric acid, and this appears to us a probable explanation.

The constitution of *isoborneol* is still uncertain, but it appears to be definitely proved that methylcamphenilol (X), the alcohol which is obtained from camphenilone by means of magnesium methyl iodide, is different from *isoborneol*. For the latter we suggest the formula below (XI), for if this is its constitution it is not difficult to understand the conversion of *isoborneol* into camphene, bornylene, borneol, or camphor respectively; at any rate, the rearrangement which would accompany such changes would be

much less profound than that which would be involved if camphene had the constitution represented by any of the other proposed formulæ.

CHEMISTRY DEPARTMENT,
THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

CCXV.—*The Action of Chlorine on Alkalis and of Carbon Dioxide on Bleaching Powder.*

By ROBERT LLEWELLYN TAYLOR.

In a former paper (*Trans.*, 1910, **97**, 2541) I stated my conclusions that the action of chlorine on alkalis, like that of bromine and of iodine, is a reversible one, and that the action of carbon dioxide on bleaching powder and similar substances is like that of other acids, the carbonic acid decomposing both the hypochlorite and the chloride.

These conclusions are controverted by S. H. Higgins (this vol., p. 858), and it appears to be necessary to reply to some of his criticisms.

I had pointed out that if the action of chlorine on alkalis is a reversible one, the action would be reversed either (a) by the removal of free alkali, or (b) by the addition of chlorides to the solution. I showed by actually sweeping it out from the solution that free chlorine is developed in a solution of bleaching powder (a) by the removal of free lime, or (b) by the addition of chlorides; in the latter case, however, to only a slight extent unless some of the free lime is removed first. I further pointed out that the development of free chlorine naturally stimulates the bleaching action of the solution, and described experiments showing that the bleaching action of a solution of bleaching powder or of sodium hypochlorite is much more rapid after the removal of free alkali, or on the addition of common salt or calcium chloride, provided there is not too much free alkali present.

Higgins says (1) that it is not so much the removal of the free lime from the solution as the further action of the carbon dioxide of the air on the solution after the free lime has been removed that increases the bleaching efficiency; (2) that the action of common salt and of calcium chloride in increasing the bleaching efficiency is due "to the increased attraction of the carbon dioxide of the air by the salt solution"; (3) that other neutral salts of sodium have an effect similar to that of the chloride in stimulating the bleaching action when used in equivalent amounts.

With regard to (1) and (2) it is sufficient to point out that, in the great majority of the author's experiments, after the removal of free alkali or the addition of salt or calcium chloride to the solution, air had no access to the solution; or, when air was used, for example, for sweeping out the chlorine and hypochlorous acid in the solution, the carbon dioxide was removed from it first. Also, in the case of further experiments presently to be described, all of them were performed in closed vessels, to which air had no access. With regard to Higgins' statement (3) that "other neutral salts of sodium have an effect similar to that of the chloride in stimulating the bleaching action," it was considered desirable that further experiments should be made.

Sodium hypochlorite solution was prepared in three different ways: (1) by passing chlorine into a cold solution of sodium hydroxide, (2) by precipitating an aqueous solution of bleaching powder with a normal solution of sodium carbonate, so that the filtered liquid gave no precipitate with either of the solutions, and (3) by exposing a solution of bleaching powder to air in a shallow dish for a few hours, in order to remove some of the free lime, and then precipitating as in (2).

* In preparing the hypochlorite by method (1), if the chlorine is passed in too long the solution smells of free chlorine, and bleaches very rapidly, and it is desirable to add more of the alkali. This was usually done until the odour of free chlorine had disappeared, and then the solution was diluted with water until it was of such a strength as to take a reasonable time for each experiment in bleaching.

The rate of bleaching was simply the time required, in comparative experiments, to more or less completely discharge the colour of similar small pieces of Turkey-red calico, previously wetted, and then immersed in the solutions.

The various solutions of hypochlorite were tried (a) alone, and (b) mixed with varying equivalent amounts of sodium chloride, sodium sulphate, and sodium nitrate. In some experiments the salts were weighed out and added in the solid state to the solutions, but more frequently measured quantities of standard solutions were used, containing respectively 117 grams of common salt, 322 grams of crystallised sodium sulphate, and 168 grams of sodium nitrate per litre.* In all such experiments the bleaching solution with which comparison was being made was diluted with water in volume equal to the amounts of the standard solutions used.

The results of a great number of experiments may be summarised as follows:

* These solutions are 2N.

I.—If the solution of the hypochlorite contains a considerable excess of free alkali, its bleaching action is extremely slow. In some experiments, when the excess of free alkali was considerable, very little bleaching occurred, even after several days. In such solutions the rate of bleaching is almost unaffected by the addition of any of the salts above mentioned. When any appreciable effect does occur, there is very little difference in the effects of the different salts used. If anything, the sodium chloride has a rather greater effect than either the sulphate or the nitrate.

II.—With solutions of hypochlorite prepared by method (1) (see above), in which only just sufficient alkali was present to prevent the odour of free chlorine in the solution, many different experiments showed that sodium chloride accelerates the bleaching action very considerably, while sodium sulphate and sodium nitrate have little or no action. In some experiments, indeed, the sodium sulphate appeared to have a distinctly retarding effect on the bleaching. The following are two experiments out of many that were tried:

A. Five c.c. of the solution of sodium hypochlorite were used in each case. This was mixed with 5 c.c. of (a) water, (b) 2*N*-solution of sodium chloride, (c) 2*N*-solution of sodium sulphate, (d) 2*N*-solution of sodium nitrate. In (b) the Turkey-red calico was completely bleached in twenty-two minutes, whilst (a), (c), and (d) all took thirty-five minutes.

B. Same as above, but with a different solution of hypochlorite. In (a) the calico was bleached in thirty minutes, in (b) twenty minutes, in (c) forty minutes, and in (d) thirty minutes.

III.—Sodium hypochlorite prepared by method (2) (see above), seeing that solutions of bleaching powder are always strongly alkaline, naturally will also contain a considerable amount of free alkali. The solution therefore bleaches very slowly; but if it has been very carefully prepared, so that there is no excess of sodium carbonate, it practically behaves like the solution prepared by method I; its bleaching action is distinctly accelerated by the addition of sodium chloride, while sodium sulphate and nitrate have little or no effect. If, however, in preparing the solution, any considerable excess of sodium carbonate is used, this has almost the same effect as free alkali. The bleaching action is greatly retarded, and none of the sodium salts has any considerable effect in accelerating it.

IV.—The solution of sodium hypochlorite prepared by method (3) behaves in almost exactly the same way as that prepared by method (1); its bleaching action is greatly accelerated by sodium

chloride, and hardly at all by equivalent amounts of sodium sulphate and nitrate.

As already pointed out (p. 1907), all the above experiments were performed in closed vessels, so that air (other than the small amount which was already in the vessels) had no access; therefore the acceleration of the bleaching action could not have been due to carbon dioxide, as suggested by Higgins.

These additional experiments amply confirm my view as to the reversibility of the action of chlorine on alkalis.

The Action of Carbon Dioxide on Bleaching Powder.

Higgins (*loc. cit.*) also objects to my suggestion that the action of carbonic acid on bleaching powder is the same as that of other acids, the carbonic acid decomposing both the hypochlorite and the chloride. This view would be represented by the following equations:

Instead of this, Higgins suggests that the action may be represented thus:

On comparing these it is obvious that there is really very little difference between them. Higgins' equation (2) is simply a combination of my (2) and (3).

Higgins' equation (2) represents what is no doubt a complex action, and dividing it into two, as I suggest, simplifies it very considerably. As Higgins points out, the reaction is the reverse of Williamson's reaction for the effect of chlorine on water containing calcium carbonate in suspension:

This also is a complex action, and doubtless takes place in two steps, the first being the action of chlorine on water (a reversible action), and the second the decomposition of calcium carbonate by hydrochloric acid:

I remember quite well that Williamson, in the 'sixties and 'seventies of last century, taught, in his lectures, that chlorine acts on water in the way represented above. He did not say in so many

words that the action was a reversible one, but he probably had such a thing in his mind. He stated in his "Chemistry for Students," of which the last edition was published in 1873, that a solution of chlorine in water always contains both hypochlorous acid and hydrochloric acid, and that the presence of the latter was proved by the fact that silver chloride was precipitated from it when silver nitrate was added. There is hardly any doubt that Williamson would have offered the same explanation of the action of chlorine on water and calcium carbonate as the one suggested above.

MUNICIPAL SCHOOL OF TECHNOLOGY,
MANCHESTER.

CCXVI.—*Experiments on the Walden Inversion.*
Part VII. Action of Phosphorus Pentachloride
and of Thionyl Chloride on Optically Active
Hydroxy-acids and Esters.

By ALEX. MCKENZIE and FRED BARROW.

THE comparison of the behaviour of phosphorus pentachloride and of thionyl chloride towards the optically active α -hydroxy- α -phenyl-propionic acids, which has been recently described by McKenzie and Clough (*Trans.*, 1910, **97**, 2564), presents a novel aspect of the Walden inversion, inasmuch as, from the *l*-hydroxy-acid, for example, it is possible to obtain either a *d*- or *l*-chloro-acid, thus:

This is obviously an instance where either phosphorus pentachloride or thionyl chloride behaves abnormally, and it is interesting to note that the displacement of the hydroxy-group by the chlorine atom proceeds in a manner parallel with the above when the active ethyl esters are used, thus:

EXPERIMENTS ON THE WALDEN INVERSION. PART VII. 1911

In the present paper an account is given of the action of phosphorus pentachloride and of thionyl chloride on a number of hydroxy-acids and esters. It is now established that a Walden inversion can be brought about in certain cases with esters of hydroxy-acids, and that the presence of a carboxyl group is not, therefore, a necessary condition for the occurrence of a Walden inversion.

The action of phosphorus pentachloride on *l*-mandelic acid is accompanied by much racemisation (McKenzie and Clough, *Trans.*, 1908, **93**, 811), and the phenylchloroacetic acid formed possesses a dextrorotation which falls considerably below the maximum value. A change of sign of rotation also occurs, as Walden has shown (*Ber.*, 1895, **28**, 1287), when esters of *l*-mandelic acid are acted on by phosphorus pentachloride. The following changes have, accordingly, been already noted:

We now find that the action of thionyl chloride is different from that of phosphorus pentachloride, inasmuch as the following changes have been effected:

Now, since it has been shown (*Trans.*, 1908, **93**, 811) that *l*-phenylchloroacetic acid can be converted into *d*-mandelic acid by the action of water and silver carbonate, the interconversion of the active mandelic acids can be brought about according to the cycle:

which may be contrasted with the changes described previously, namely:

The racemisation which accompanies the displacement of the

hydroxy-group by the chlorine atom is much less pronounced when thionyl chloride is used in place of phosphorus pentachloride. In the case of the acid this is probably due to some extent to the fact that the action of thionyl chloride can be conducted at comparatively low temperatures. The phenylchloroacetic acid obtained by the interaction of thionyl chloride and *l*-mandelic acid had $[\alpha]_D -101.3^\circ$ in benzene solution, whereas the pure acid, free from the *r*-isomeride, has $[\alpha]_D -191^\circ$ in the same solvent. Again the dextrorotatory ethyl phenylchloroacetate, prepared by Walden (*loc. cit.*) by the action of phosphorus pentachloride on a solution of ethyl *l*-mandelate in chloroform, had $[\alpha]_D +25.19^\circ$, whilst the product obtained by the authors from thionyl chloride and ethyl *l*-mandelate possesses a much higher activity, namely, $[\alpha]_D -64^\circ$. A Walden inversion occurs, of course, in the case of the ester, either with phosphorus pentachloride or with thionyl chloride, but, although the racemisation is pronounced in the former case, this aspect can hardly be emphasised in favour of the view that phosphorus pentachloride acts abnormally.

The action of thionyl chloride on *r*-mandelic acid has been studied by Hans Meyer (*Monatsh.*, 1901, 22, 415), who states: "Mandelsäure wird glatt unter Bildung von Benzaldehyd gespalten," and the formation of benzaldehyde is assumed to occur, owing to the disruption of the sulphito-chloride, $C_6H_5 \cdot CH(OSOCl) \cdot COCl$, with evolution of carbon monoxide and regeneration of thionyl chloride. We were unable to confirm this observation. Phenylchloroacetic acid is produced, although in small yield, by the action of water on the oil resulting from the treatment of *r*-mandelic acid with thionyl chloride, whilst the main product is benzylidene chloride. There was no evidence of the presence of benzaldehyde, and the action probably occurs according to the equations:

It is, however, conceivable that benzaldehyde is actually formed as an intermediate product, more especially since Hoering and Baum (*Ber.*, 1908, 41, 1918) mention that benzylidene chloride can be formed in almost quantitative yield by the interaction of thionyl chloride and benzaldehyde.

As is well known, the action of phosphorus pentachloride on *l*-malic acid (or its esters) is accompanied by a change of sign of rotation (Walden). The authors have examined the behaviour of

thionyl chloride, and find that it is similar to that of pentachloride, thus:

and

The sulphito-ester, obtained from thionyl chloride and ethyl *d*-tartrate, was found to possess a much higher levorotation than that quoted by Schiller (*Ber.*, 1909, 42, 2017). Attempts to bring about the interconversion of the optically active tartaric acids by the aid of this compound were unsuccessful.

McKenzie and Wren (*Trans.*, 1910, 97, 1355) have already described the interconversion of the optically active α -hydroxy- β -phenylpropionic acids which has been effected according to the cycle:

The oil obtained by the action of phosphorus pentachloride on the *d*-hydroxy-acid was dextrorotatory, but since it gave the *L*-hydroxy-acid on decomposition with calcium carbonate and water, it is probable that *d*- α -chloro- β -phenylpropionyl chloride corresponds in configuration with *L*- α -chloro- β -phenylpropionic acid. It was shown that the displacement of bromine in the active α -bromo- β -phenylpropionic acids gave hydroxy-acids of the same sign of activity as the bromo-acid used, no matter under what conditions the displacement was conducted; this action may be taken as normal. Further, it was pointed out that the action of phosphorus pentachloride is doubtless abnormal, the assumption being made that the behaviour of the active α -chloro- β -phenylpropionic acids towards calcium carbonate and water is similar to that of the α -bromo- β -phenylpropionic acids.

We have carried out a considerable number of experiments on the behaviour of the active ethyl esters of α -hydroxy- β -phenylpropionic acid towards phosphorus pentachloride and thionyl chloride respectively, and also on the action of thionyl chloride on the free acids. These changes are unfortunately complicated by the occurrence of side-reactions (compare Scheibler and Wheeler, *Ber.*, 1911, 44, 2689), and our results have on this account little value. It is well known from the work of Anschütz and others that the action of phosphorus pentachloride on hydroxy-compounds

is frequently attended with the formation of phosphorus derivatives, whilst Bistrzycki and Landtwing (*Ber.*, 1908, **41**, 686), in continuation of the exhaustive researches of the former on carbon monoxide scission, have shown how readily the latter phenomenon occurs when certain acid chlorides are heated. It appears, however, that phosphorus pentachloride and thionyl chloride behave differently towards the active esters, inasmuch as the direction of rotation is unchanged with the former, and changed with the latter. The action of phosphorus pentachloride may accordingly be used to interconvert the acids as follows:

Inasmuch as we find that the levorotatory acid chloride resulting from the interaction of phosphorus pentachloride and the *l*-hydroxy-acid gives a levorotatory ester when acted on by ethyl alcohol, it is possible that the acids can be interconverted according to the following changes:

The contrast with thionyl chloride is indicated by the following scheme:

Since the bulk of the research on the Walden inversion has been confined to α -hydroxy-acids and their derivatives, the investigation of β -hydroxy-acids, where the carboxyl group is not directly attached to the asymmetric carbon atom, is of particular importance. At first it appeared that a Walden inversion could not be effected with this type, for example:

(E. Fischer and Scheibler, *Ber.*, 1909, **42**, 1219.)

(McKenzie and Humphries, *Trans.*, 1910, **97**, 121.)

(E. Fischer, Scheibler, and Groh, *Ber.*, 1910, **43**, 2020.)

It has, however, been recently shown by E. Fischer and Scheibler (*Sitzungsber. K. Akad. Wiss. Berlin*, 1911, **26**, 566; *Annalen*, 1911, **383**, 337) that the following changes can be carried out:

It is therefore obvious that a Walden inversion must have occurred during one of these stages, and the phenomenon is accordingly not confined to α -substituted acids.

In this connexion we have studied the optically active β -hydroxy- β -phenylpropionic acids. The action of hydrochloric acid and of phosphorus pentachloride on the *d*-hydroxy-acid gives a levorotatory chloro-acid, and when this is boiled with water the parent hydroxy-acid is regenerated (compare McKenzie and Humphries, *loc. cit.*), thus:

The behaviour of thionyl chloride is, however, different, and the interconversion of the hydroxy-acids was realised in accordance with the following scheme:

These changes are accompanied with a considerable amount of racemisation. It was noteworthy that the action of thionyl chloride gave a much more active acid chloride than in the case of phosphorus pentachloride; with thionyl chloride the crude product resulting from the *d*-hydroxy-acid had $\alpha_D^{25} + 25.38^\circ$ in a 3 mm. tube, whilst with pentachloride α_D was only -1.25° . The former product was necessarily contaminated with cinnamoyl chloride owing to the elimination of hydrogen chloride during the preparation; when, however, it was decomposed by water, the cinnamic and the hydroxy-acid were easily separated from one another. We consider it probable that the Walden inversion is caused by the thionyl chloride, and not by the water.

The above-mentioned cycle represents the first instance recorded of the interconversion of β -hydroxy-acids by the Walden inversion.

EXPERIMENTAL.

Action of Thionyl Chloride on r-Mandelic Acid.

Fifty grams of *r*-mandelic acid were heated with 100 grams of thionyl chloride for seven hours until the evolution of hydrogen chloride ceased. After removal of the excess of thionyl chloride, 30 grams of a pale yellow oil, boiling at 90–120°/13 mm., were collected, and then the product in the distilling flask began to decompose. Since the oil had not solidified when left overnight in contact with a large excess of water, it was separated from the latter by means of ether, and the acid present in the ethereal solution was removed by aqueous sodium carbonate. The phenylchloroacetic acid obtained from the sodium salt by acidification with mineral acid and extraction with ether amounted to 7.5 grams. The ethereal solution from which the phenylchloroacetic acid had been removed was evaporated, and the residual oil fractionated under diminished pressure, when it was found to consist mainly of benzylidene chloride. The latter compound was isolated without difficulty, and identified by its odour, boiling point, and analysis.

Action of Thionyl Chloride on l-Mandelic Acid. Conversion of l- into d-Mandelic Acid.

Ten grams of *l*-mandelic acid (1 mol.) and 24 grams of thionyl chloride (3 mols.) were heated at 50° for one hour, then boiled gently during two hours, and finally allowed to remain at the ordinary temperature for seven days. After removal of the thionyl chloride, the residual yellow oil was distilled under diminished pressure, when 4.5 grams, boiling at 97–102°/13 mm., were collected. This oil showed no tendency to solidify when left in contact with water overnight, whereas the product obtained by the interaction of phosphorus pentachloride and *l*-mandelic acid (Trans., 1908, 93, 811) readily solidifies under these conditions. The phenylchloroacetic acid which was isolated as indicated in the preceding experiment amounted to 2.1 grams. It melted at 45–52° to a turbid liquid, which became clear at 65°, and was a mixture of the *r*- and *l*-acids, with the following rotation in benzene solution:

$$l=2, c=3.656, \alpha_D^{25} = -7.41^\circ, [\alpha]_D^{25} = -101.3^\circ.$$

On crystallising this acid from a mixture of benzene and light petroleum, the crystals which separated contained a larger proportion of the racemic acid than did the original acid (compare Trans., 1909, 95, 785), the following value for the specific rotation having been determined in benzene solution:

$$l=2, c=1.702, \alpha_D^{25} = -1.49^\circ, [\alpha]_D^{25} = -43.8^\circ.$$

The mother liquor from this product was allowed to evaporate spontaneously at the ordinary temperature. The resulting phenylchloroacetic acid (1.05 grams) had, of course, a higher optical activity than that of the original acid. In benzene solution:

$$l = 2, c = 2.394, \alpha_D^{25} = -7.00^\circ, [\alpha]_D^{25} = -146.2^\circ.$$

0.1265, dissolved in ethyl alcohol, required 23.5 c.c. *N*/31.5-baryta for neutralisation, the calculated amount being 23.4 c.c.

The pure *l*-acid obtained by the resolution of the *r*-acid with morphine (*loc. cit.*) has $[\alpha]_D^{25} = -191^\circ$ in benzene solution.

When the chlorine in the above levorotatory acid was displaced by the hydroxy-group by the aid of silver carbonate and water, a dextrorotatory mandelic acid was obtained. The chloro-acid (0.65 gram) with $[\alpha]_D = -146.2^\circ$ was shaken with 40 c.c. of water at the ordinary temperature for half a minute, and then treated with silver carbonate, which had been freshly precipitated from 2 grams of nitrate. After one and a-half hours at the ordinary temperature with occasional shaking, the mixture was heated on the water-bath for one and a-half hours. Dilute hydrochloric acid was added, and the silver chloride removed. The filtrate (60 c.c.) was dextrorotatory, 25 c.c. of it in a 4-dm. tube giving $\alpha_D = +1.39^\circ$. The mandelic acid extracted from this solution in the usual manner gave the following value in ethyl-alcoholic solution:

$$l = 2, c = 1.73, \alpha_D^{25} = +1.83^\circ, [\alpha]_D^{25} = +52.9^\circ.$$

Action of Thionyl Chloride on l-Mandelic Esters.

Methyl *l*-mandelate (4.3 grams) and thionyl chloride (12 grams) were mixed, and allowed to remain at the ordinary temperature for twenty-four hours. Since the action was incomplete, the solution was heated at 50–60° for one hour, and finally on the water-bath for two hours until the evolution of hydrogen chloride ceased. The ester was then distilled under diminished pressure, when 3.8 grams were obtained.

Methyl *l*-phenylchloroacetate, $C_6H_5 \cdot CHCl \cdot CO_2Me$, is a colourless oil, boiling at 123–126°/11 mm.:

0.251 gave 0.1956 AgCl. $Cl = 19.3$.

$C_9H_9O_2Cl$ requires $Cl = 19.2$ per cent.

The specific rotation was determined:

$$l = 1, D_4^{25} 1.213, \alpha_D^{25} = -105.15^\circ, [\alpha]_D^{25} = -86.7^\circ.$$

The hydrolysis of this ester was conducted as follows. One gram was added to 10 c.c. of aqueous hydrochloric acid saturated at 0°, and the mixture kept at the ordinary temperature for six days, with occasional shaking. When the viscid oil was nucleated with *l*-phenylchloroacetic acid, crystals began to form slowly after a time.

Water was added, and the mixture of acid and unattacked ester extracted with ether. The acid was removed from the ethereal solution by aqueous sodium carbonate, and was then isolated in the usual manner. The resulting phenylchloroacetic acid (0.42 gram) was levorotatory in benzene solution:

$$l=2, c=2.09, \alpha_D -3.27^\circ, [\alpha]_D -78.2^\circ.$$

0.1078, in ethyl-alcoholic solution, required 19.8 c.c. $N/31.5$ -baryta for neutralisation. Calc., 19.9 c.c.

Ethyl *l*-mandelate (7 grams) and thionyl chloride (20 grams) were mixed, and kept at the ordinary temperature for four days, by which time the evolution of hydrogen chloride had ceased. Ethyl *l*-phenylchloroacetate is a colourless oil, and boils at 132–133°/15 mm.

0.3366 gave 0.2406 AgCl. Cl=17.7.

$C_{10}H_{11}O_2Cl$ requires Cl=17.9 per cent.

The specific rotation was determined:

$$l=0.5, D_4^{25} 1.162, \alpha_D^{25} -37.18^\circ, [\alpha]_D^{25} -64.0^\circ.$$

The phenylchloroacetic acid obtained by conducting the hydrolysis in the manner already described in the case of the methyl ester was levorotatory in benzene solution:

$$l=2, c=3.26, \alpha_D -4.38^\circ, [\alpha]_D -67.2^\circ.$$

The displacement of chlorine in methyl *l*-phenylchloroacetate by alkoxy-groups was examined. A solution of 1 gram of the chloro-ester in 10 c.c. of methyl alcohol was boiled for one and a-half hours with a solution of 0.4 gram of sodium in 5 c.c. of methyl alcohol. The sodium chloride was drained off, and the filtrate, when polarimetrically examined in a 2-dm. tube, was found to be inactive. The acid isolated from the sodium salt was identified by its melting point and analysis as *r*-phenylmethoxyacetic acid.

The behaviour of sodium ethoxide towards the chloro-ester was similar.

This type of racemisation has a parallel in the observations of Purdie and Williamson (Trans., 1896, 69, 820) dealing with the action of sodium ethoxide on ethyl *d*- α -chloropropionate and ethyl *l*- α -bromopropionate respectively. It was suggested by these authors that in actions of this type, halogen acid is eliminated with the subsequent addition of alcohol, a view which has support from the behaviour of esters of unsaturated acids towards alcohols in the presence of traces of sodium ethoxide.

Action of Thionyl Chloride on l-Malic Acid.

Eight grams of powdered *l*-malic acid and 28 grams of thionyl chlorides were allowed to remain at the ordinary temperature, when

slow evolution of hydrogen chloride took place. After nine days the solid present was removed, and found by analysis and termination of rotation to consist of unaltered malic acid.

The displacement, however, of the alcoholic hydroxy-group in malic acid takes place readily under the following conditions. Six grams of the acid and 22 grams of thionyl chloride were heated in the water-bath for one hour. The action was vigorous, and the acid gradually dissolved. The excess of thionyl chloride was removed under diminished pressure, and the residual viscid oil was dissolved in 50 c.c. of water. The chlorosuccinic acid was separated from the malic acid present by extraction with ether. The yield of crude chloro-acid was 2 grams, and, after one crystallisation from benzene containing a little acetone, it melted at $174-176^{\circ}$. The specific rotation was determined in aqueous solution:

$$l = 2, c = 2.706, \alpha_D^{25} + 1.09^{\circ}, [\alpha]_D^{25} + 20.1^{\circ}.$$

Wilden and Marshall (Trans., 1895, 67, 494) give $[\alpha]_D^{25} - 19.67^{\circ}$ for *l*-chlorosuccinic acid, obtained by the action of nitrosyl chloride on *l*-asparagine. According to Walden (Zeitsch. physikal. Chem., 1906, 17, 253), *d*-chlorosuccinic acid, obtained by the action of phosphorus pentachloride on *l*-malic acid, melts at 174° , and has $[\alpha]_D^{25} + 20.27^{\circ}$.

It is therefore possible to obtain readily by the above method pure *d*-chloro-acid by the action of thionyl chloride on *l*-malic acid. Partial racemisation does, however, occur if the initial heating with thionyl chloride is prolonged. For example, when 7 grams of *l*-malic acid were heated with 24 grams of thionyl chloride for one and a-half hours, the crude chlorosuccinic acid amounted to 1.5 grams, and even after two crystallisations from benzene containing a little acetone, its melting point was low, namely, 159° , and its specific rotation in aqueous solution was only $+1.1^{\circ}$.

Action of Thionyl Chloride on Ethyl l-Malate.

Ethyl *l*-malate (7.6 grams, 1 mol.) was added to thionyl chloride (7.6 grams, 1 mol.), and, after four days at the ordinary temperature, the liquid was distilled under diminished pressure. The optical activity of the main fraction was determined, and the value obtained did not alter when the product was redistilled. Yield, 6.5 grams.

Ethyl d-chlorosuccinate, $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{CHCl}\cdot\text{CO}_2\text{Et}$, is a colourless liquid, which boils at $124^{\circ}/18$ mm.:

$n_D^{20} 1.3713$ gave 0.1858 AgCl. $\text{Cl} = 16.9$.

$\text{C}_8\text{H}_{14}\text{O}_4\text{Cl}$ requires $\text{Cl} = 17.0$ per cent.

It has $D_4^{25} 1.152$ and $\alpha_D^{25} + 37.73^{\circ}$ ($l = 1$); whence $[\alpha]_D^{25} + 32.7^{\circ}$.

VOL. XCIX.

The latter value is higher than that quoted by Walden (*Ber.*, 1895, **28**, 1290), who prepared the ester from *d*-chlorosuccinic acid by the hydrogen chloride method, and obtained a product with $[\alpha]_D + 27.5^\circ$. Walden's ester was thus partly racemised, but it is also doubtful if the compound, as obtained by us, possesses the maximum activity, especially since we find that partial racemisation does actually occur when the temperature is raised during the interaction of thionyl chloride (in slight excess) and ethyl *L*-malate. For example, 10 grams of the malate and 10 grams of thionyl chloride were allowed to remain for fifteen hours at the ordinary temperature, after which time a slight evolution of hydrogen chloride was still perceptible. The action was completed by boiling on the water-bath for three-quarters of an hour. The resulting ester had $\alpha_D^{18} + 31.04^\circ$ in a 1-dm. tube. Further, the ester with $[\alpha]_D^{18} + 32.7^\circ$ gave a partly racemised chlorosuccinic acid when it was hydrolysed with fuming hydrochloric acid, but, of course, this effect may have been brought about during the hydrolysis; the chloro-acid obtained melted indefinitely at $162-166^\circ$, and had $[\alpha]_D + 18.7^\circ$ in aqueous solution.

Action of Thionyl Chloride on Ethyl d-Tartrate.

Carius (*Annalen*, 1859, **111**, 94) has shown that esters of sulphurous acid are formed by the interaction of thionyl chloride and alcohols, whilst Moers (*Unang. Diss.*, Berlin, 1907) obtained the compound $(OEt)_2CH \cdot CH \begin{smallmatrix} \text{CH}_2 \cdot O \\ \diagdown \quad \diagup \\ O \quad SO \end{smallmatrix}$ by the action of thionyl chloride on glycerol acetal. Schiller (*Ber.*, 1909, **42**, 2017) accordingly studied the behaviour of tartaric esters towards thionyl chloride, and showed that the action proceeds thus:

Since this sulphito-ester, as described by Schiller, has a rotation opposite in sign to the tartrate used, we were led to prepare it with the object of regenerating tartaric acid from it in order to find out whether an interconversion of the active tartaric acids could be effected through a Walden inversion. Such an interconversion does not, however, occur.

The method employed differed in detail from that described by Schiller, and it gave a satisfactory yield of a product, which, on polarimetric examination, gave a value very much higher than Schiller's. Evolution of hydrogen chloride began at once at the ordinary temperature when 12 grams of thionyl chloride were added to 15 grams of ethyl *d*-tartrate. After two weeks at the ordinary

EXPERIMENTS ON THE WALDEN INVERSION. PART VII. 1921

temperature, the thionyl chloride was removed, and the residue distilled under diminished pressure. A pale yellow oil was obtained boiling at 160°/12 mm., whereas Schiller gives 167°/11.5 mm. (Found, S=12.6. Calc., S=12.7 per cent.)

The following values were obtained:

$$l=1, D_4^{25} 1.329, \alpha_D^{25} -244.3^\circ, [\alpha]_D^{25} -183.8^\circ;$$

$$l=0.5, D_4^{25} 1.342, \alpha_D^{25} -124.4^\circ, [\alpha]_D^{25} -185.4^\circ.$$

Schiller's values are as follows:

$$D^{25} 1.3257, [\alpha]_D^{25-28} -56.71^\circ.$$

We have also examined the compound in ethyl-alcoholic solution, with the result:

$$l=2, c=4.703, \alpha_D -17.78^\circ, [\alpha]_D -189.0^\circ.$$

The ester was then decomposed by heating with aqueous sodium hydroxide, when sulphurous acid was readily eliminated. In this operation a change of sign of rotation occurred, and *d*-tartaric acid was obtained from the product by conversion into lead salt and decomposition of the latter with hydrogen sulphide.

Action of Phosphorus Pentachloride on *d*- and *l*-*Hydroxy-β*-phenylpropionates.

d-*α*-Hydroxy-*β*-phenylpropionic acid, prepared as previously described (Trans., 1910, 97, 1355) by the resolution of the *r*-acid by morphine, was converted into its ethyl ester by the hydrogen chloride method.

Ethyl *d*-*α*-hydroxy-*β*-phenylpropionate, $C_6H_5 \cdot CH_2 \cdot CH(OH) \cdot CO_2Et$,

when freshly distilled, is a colourless oil, and boils at 152—154°/20 mm. It has $D_4^{17} 1.105$ and $\alpha_D^{17} +8.40^\circ$; whence $\alpha_D^{17} +7.6^\circ$.

On keeping overnight, the ester in the neck of the distilling flask used had solidified, and, after some days, a nucleus of this solid was added to the main lot of oil, when solidification of the latter occurred at once. Several preparations both of this ester and of its *l*-isomeride were carried out subsequently, but on no occasion did these esters fail to solidify soon after distillation, and when left exposed to the atmosphere of the laboratory, which had in the meantime doubtless become infected with the esters (compare Büllmann's work on the isomerism of the cinnamic acids).*

The solid *d*-ester melts at 46—47°:

0.2375 gave 0.5923 CO₂ and 0.1574 H₂O. C=68.0; H=7.4.

C₁₁H₁₄O₃ requires C=68.0; H=7.3 per cent.

* The corresponding *dl*-ester, prepared from ethyl *β*-phenyl-*α*-diazopropionate by Curtius and Müller (Ber., 1904, 37, 1268), is described as an oil.

The ester separates from light petroleum (b. p. 60–80°) in fine, long, felted needles. It is readily soluble in cold ethyl alcohol, benzene, or acetone, and, when its specific rotation was determined in these solvents, it was found to be levorotatory in ethyl-alcoholic solution:

$$l = 2, c = 6.074, \alpha_D^{19.5} = -0.58^\circ, [\alpha]_D^{19.5} = -4.8^\circ.$$

In benzene solution:

$$l = 2, c = 3.982, \alpha_D^{17.5} = +1.79^\circ, [\alpha]_D^{17.5} = +22.5^\circ.$$

In acetone solution:

$$l = 2, c = 4.272, \alpha_D^{17.5} = +1.16^\circ, [\alpha]_D^{17.5} = +13.6^\circ.$$

The enantiomorphously related ester was also prepared from the *l*-acid.

Ethyl 1- α -hydroxy- β -phenylpropionate boils at 159–160°/26 mm., and solidified on cooling. It has m. p. 46–47°, and the value for its rotation in benzene solution was in agreement with that of the *d*-ester:

$$l = 2, c = 4.03, \alpha_D^{19.5} = -1.82^\circ, [\alpha]_D^{19.5} = -22.6^\circ.$$

The *l*-hydroxy-ester (6 grams) was heated with phosphorus pentachloride (6.7 grams) for about two hours at 100°, but, judging from the amount of pentachloride which had separated out overnight, it was obvious that the action was incomplete under these conditions. After one hour at 130°, the product was then distilled under diminished pressure, and the fraction boiling between 152° and 170°/18 mm. was collected. It was *levorotatory*, giving $\alpha_D = 2.2^\circ$ in a 1-dm. tube. Attempts to prepare a uniform product from it by further fractionation were unsuccessful. The various fractions, amounting to 5 grams, were then hydrolysed by boiling with calcium carbonate and aqueous alcohol, and a *dextrorotatory* aqueous solution of calcium salt was obtained, the observed value in a 2-dm. tube being $\alpha_D = 0.63^\circ$.

The *d*-hydroxy-ester, when treated in chloroform solution with phosphorus pentachloride, gave a similar result.

The *l*-hydroxy-acid (4.7 grams) was acted on by phosphorus pentachloride (11.7 grams), as described by McKenzie and Wren (*loc. cit.*) for the *d*-acid. After distillation under diminished pressure, the product was levorotatory, its solution in an equal volume of ether giving $\alpha_D = -8.5^\circ$ in a 1-dm. tube. On treatment with ethyl alcohol, an oil was obtained; the main portion boiled at 162–171°/23 mm. The amount of material was too small to admit of further purification, but it was found that the liquid gave $[\alpha]_D = -12.1^\circ$ in ethyl-alcoholic solution.

Action of Thionyl Chloride on Ethyl 1- α -Hydroxy- β -phenylpropionate.

Ethyl 1- α -hydroxy- β -phenylpropionate (6 grams) and thionyl chloride (12 grams) were allowed to remain at the ordinary temperature for one and a-half hours, then heated within half an hour to 50°, and maintained at this temperature for one hour, and finally heated for two and a-half hours on the water-bath. On fractionation, 3.5 grams, b. p. 129—138°/8 mm., were obtained, and this was dextrorotatory, giving $\alpha_D + 19.18^\circ$ in a 50 mm. tube. On decomposition with calcium carbonate and aqueous alcohol, it gave an aqueous solution of calcium salt, which was laevorotatory.

Several experiments were also carried out on the action of thionyl chloride on the *r*- and *l*-hydroxy-acids with no positive result, owing to the decomposition which occurred during the distillation of the acid chloride.

Action of Hydrochloric Acid on d- and l- β -Hydroxy- β -phenylpropionic Acids.

The optically active acids were prepared from the *r*-acid by the method previously described (Trans., 1910, 97, 121).

Eight grams of *d*- β -hydroxy- β -phenylpropionic acid were added to 120 c.c. of fuming hydrochloric acid (saturated at 0°), cooled to -10°. On shaking, the bulk of the hydroxy-acid dissolved, and, after ten minutes, the chloro-acid began to crystallise out. The mixture remained in the freezing mixture for two hours, and, after fifteen hours at the ordinary temperature, the voluminous precipitate was drained off; yield about 8 grams, $[\alpha]_D$ in ethyl-alcoholic solution -12°. The acid, when crystallised from benzene, separated in lustrous leaflets (6.2 grams) with $[\alpha]_D - 7.1^\circ$ in ethyl alcohol. This acid contained 18.85 per cent. Cl, whereas

requires 19.2 per cent. After one further crystallisation, the optical activity dropped to $[\alpha]_D - 4.6^\circ$ in ethyl alcohol. (Found, Cl=19.0 per cent.) A change of sign of rotation took place when the chlorine in the latter acid was displaced by the hydroxy-group by boiling with water. A little cinnamic acid was formed in this operation. The resulting hydroxy-acid was slightly but distinctly dextrorotatory; a solution of 3 grams, made up to 20 c.c. of ethyl alcohol, gave $\alpha_D + 0.29^\circ$ in a 4-dm. tube, and the dextrorotation still was evident when the product was crystallised from benzene.

The change

was also confirmed by the action of water on the chloro-acid, obtained from the mother liquors, from which the acids with $[\alpha]_D -7.1^\circ$ and -4.6° had been removed. Two grams of this acid with $[\alpha]_D -21.7^\circ$ were boiled with water in an open flask for one and a-quarter hours. Some styrene was produced, and also a little cinnamic acid, which was removed. The hydroxy-acid was extracted with ether in a continuous extraction apparatus. It amounted to 1.1 grams, and was dextrorotatory, 0.8658 , dissolved in ethyl alcohol and made up to 10 c.c., giving $\alpha_D +0.21^\circ$ in a 2-dcm. tube. The dextrorotation persisted in the product obtained by crystallisation from benzene, the $[\alpha]_D$ being only $+0.9^\circ$ in ethyl alcohol. (Found, C=64.9; H=6.3. Calc., C=65.0; H=6.1 per cent.)

The optical activity of the crude chloro-acid varies considerably in value according to the conditions under which the action of hydrochloric acid is conducted. In the preceding experiment, the specific rotation of the crude acid was -12° , but in one experiment with the *l*-hydroxy-acid, when the product was removed after four hours at about -15° in contact with fuming hydrochloric acid, the crude chloro-acid had $[\alpha]_D +21.8^\circ$. On the other hand, in an experiment with the *l*-hydroxy-acid where the action was conducted at the ordinary temperature, the $[\alpha]_D$ of the product was only $+6.5^\circ$.

Action of Phosphorus Pentachloride on d-β-Hydroxy-β-phenylpropionic Acid.

Phosphorus pentachloride (21 grams) was gradually added to *d*-β-hydroxy-β-phenylpropionic acid (8 grams), the operation being conducted by cooling the mixture to -15° from time to time in order to avoid, so far as possible, any racemisation which might occur by the temperature being too high. After five days at the ordinary temperature, a small amount of pentachloride remained unattacked, and the mixture was therefore heated for ten minutes until all dissolved. After removal of the phosphoryl chloride, the residue containing the chloro-chloride was *laevorotatory*, giving $\alpha_D^{25} -1.25^\circ$ in a 50 mm. tube. This oil was decomposed by moist ether, and the solid product containing the chloro-acid was also *laevorotatory* in ethylalcoholic solution:

$$l=4, c=8.5184, \alpha_D -0.44^\circ, [\alpha]_D -1.3^\circ.$$

Reaction of Thionyl Chloride on d- and l-β-Hydroxy-β-phenylpropionic Acids. Interconversion of the Acids.

Preliminary experiments indicated that a sulphito-chloride is produced by the action of thionyl chloride on the β-hydroxy-phenylpropionic acids, and that the change

requires a fairly high temperature for its completion. The resulting β-chloro-β-phenylpropionyl chloride also contained a large amount of cinnamoyl chloride due to the elimination of hydrogen chloride.

A mixture of *d*-β-hydroxy-β-phenylpropionic acid (8 grams) and thionyl chloride (20 grams) remained at the ordinary temperature for fifteen hours, and was then boiled for twenty minutes. After removal of the thionyl chloride, the residual oil was distilled under diminished pressure, when a large amount of gas was evolved. On distillation, a colourless, strongly refractive liquid (5 grams) was obtained, boiling at 137–137.5°/12 mm. It had $n_D^{20} + 25.38^\circ$ in a 50 mm. tube, and a halogen determination showed that it contained no less than 48 per cent. of cinnamoyl chloride. It was hydrolysed by moist ether, and 3.8 grams of lustrous, colourless leaflets were obtained, which were examined in ethyl-alcoholic solution:

$$l = 2, c = 3.836, \alpha_D^{18} + 2.54^\circ, [\alpha]_D^{18} + 33.1^\circ.$$

This product was separated into two fractions by crystallisation from benzene. The crystals which separated consisted of β-chloro-β-phenylpropionic acid and cinnamic acid, the latter being present to the extent of 39 per cent.; in ethyl-alcoholic solution, the value $[\alpha]_D + 21.0^\circ$ for $c = 4.436$ was obtained. On evaporation of the mother liquor, the product gave $[\alpha]_D + 44.7^\circ$ for $c = 5.498$.

The action of water on these mixtures of cinnamic acid, *r*- and *d*-β-chloro-β-phenylpropionic acids, was next investigated. The product (1.3 grams) with $[\alpha]_D + 21.0^\circ$ was boiled with water (50 c.c.) for several hours; the odour of styrene was perceptible, and, on cooling, cinnamic acid (0.62 gram) separated. The latter was removed, and the hydroxy-acid extracted with ether in a continuous apparatus. After crystallisation of the product from benzene, 0.42 gram of hydroxy-acid was obtained (Found, C = 64.9; H = 6.1. Calc., C = 65.0; H = 6.1 per cent.); it melted at 95–102°, and was a mixture of *r*- and *l*-β-hydroxy-β-phenylpropionic acids. The optical activity was slight, but distinct. In ethyl-alcoholic solution:

$$l = 0.5, c = 13.8, \alpha_D - 0.24^\circ, [\alpha]_D - 3.5^\circ.$$

The homogeneous *l*-acid, according to McKenzie and Humphries (*loc. cit.*), has $[\alpha]_D -18.9^\circ$.

This result was confirmed by the action of water on the product with $[\alpha]_D +44.7^\circ$. One and a-half grams of this, when decomposed by water, gave 0.55 gram of cinnamic acid and 0.55 gram of crude hydroxy-acid, which, after crystallisation from benzene, amounted to 0.44 gram. (Found, C=65.0; H=6.15. Calc., C=65.0; H=6.1 per cent.) In ethyl-alcoholic solution, the latter acid was laevorotatory:

$$l = 0.5, c = 15.33, \alpha_D -0.44^\circ, [\alpha]_D -5.7^\circ.$$

The residue remaining in the flask after distillation of the chloro-chloride in the preceding experiment solidified on cooling, and was purified by crystallisation from ethyl alcohol, from which it separated in very pale yellow needles, melting at 134° . Yield, 1.1 grams. The compound proved to be optically inactive, and insoluble in sodium hydroxide. It had the properties of cinnamic anhydride, which, according to Liebermann, melts at 133° . (Found, C=77.5; H=5.3. Calc., C=77.7; H=5.1 per cent.) Its molecular weight in benzene solution gave the value 266 (calc., 278). Its phenyl-hydrazide separated from a mixture of ethyl alcohol and water in yellow needles, m. p. $186-187^\circ$, whereas Wedekind (*Ber.*, 1901, 34, 2075) gives 187° .

The conversion of the *l*-hydroxy-acid into its *d*-isomeride was also carried out. The oil resulting from the action of thionyl chloride (28 grams) on *l*- β -hydroxy- β -phenylpropionic acid (10 grams) was distilled twice, and, as in the preceding experiment, a large quantity of gas was evolved during the first distillation. The product (6 grams) had $\alpha_D^{21} -13.75^\circ$ in a 50 mm. tube, and boiled at $145-147^\circ/23$ mm. The mixture of chloro-acid and cinnamic acid obtained from it amounted to 5 grams, and had $[\alpha]_D -14.3^\circ$ in ethyl-alcoholic solution. The hydroxy-acid, obtained from this by the action of water, was separated from cinnamic acid, and then gave $[\alpha]_D +3.4^\circ$ in ethyl-alcoholic solution.

The authors are indebted to the Government Grant Committee of the Royal Society for a grant in aid of this research.

CCXVII.—*The Relation between Residual Affinity and Chemical Constitution. Part II. Certain Compounds of Nitrogen.*

By HANS THACHER CLARKE (1851 Exhibition Scholar).

In a previous communication (Trans., 1910, 97, 416) an account was given of a study of the reactivity of the halogen atom in certain organic halogen compounds when allowed to react with alcoholic pyridine. In the present work an attempt has been made to examine the effects of chemical constitution in a series of simple aliphatic tertiary amines containing two nitrogen atoms by a study of their reactivity towards alcoholic benzyl chloride, under standard conditions, as well as by an examination of the refractive powers of the comparable members of this series. The results of the reaction-velocity measurements are more difficult to interpret than in the case of the halogen compounds; only those substances which are of similar constitution have therefore been directly compared, in order to avoid, so far as possible, the introduction of the indeterminable influence due to steric considerations, as well as those due to structure demonstrated by N. Menshutkin (*Ber.*, 1897, 30, 2775, etc.).

In the course of an examination of the properties of diethoxy-

Dr. Smiles and the present author (Trans., 1909, 95, 992) were led to the conclusion that the sulphur and oxygen atoms situated in the 1:4-position in the saturated cyclic system exercised a mutual influence on each other, as shown by subnormal reactivity and exalted refractive power. In order to ascertain whether this phenomenon is constant throughout the series of six-membered cyclic compounds containing unsaturated atoms in the 1:4-positions, an extensive examination of such compounds has been undertaken. In the present paper the question of the piperazines is discussed.

The dialkylpiperazines may be prepared by the interaction of two molecules of ethylene bromide with two molecules of a primary amine, in the presence of some agent which will eliminate halogen hydride:

For purposes of comparison, the corresponding open-chain methyl derivatives of ethylenediamine were selected:

A comparison of the refractive powers of the two classes of compound is thus readily effected with a minimum possible error, merely by subtracting the atomic refractions of two hydrogen atoms from the dimethyl derivative.

In carrying out the reactivity measurements, equal volumes of an *N*/2-solution of benzyl chloride and an *N*/4-solution of the tertiary diamine (or an *N*/2-solution of the tertiary monoamine) in absolute alcohol were mixed and maintained at 56°, aliquot portions being withdrawn from time to time and titrated by Volhard's method with *N*/25-solutions of silver nitrate and potassium thiocyanate. Owing to the complicated nature of the reaction, velocity-constants were in general not obtainable; the results are therefore expressed graphically by plotting the percentage of quaternary ammonium salt formed against the time. For purposes of comparison, it may perhaps be convenient to quote the times necessary to bring about 10 per cent. of the complete reaction, assuming total combination to be in all cases possible.

The first series shows the relative reactivities of a simple tertiary amine, a tertiary diamine, and a disubstituted piperazine, these being selected so as to be as nearly as possible comparable:

		Time for 10 per cent. reaction.
Ethylpiperidine	$C_5H_{10}NEt$	40 mins.
Ethylenedipiperidine ...	$C_5H_{10}N \cdot CH_2 \cdot CH_2 \cdot NC_5H_{10} \dots$	2 hrs., 45 mins.
Diethylpiperazine	$EtN \begin{array}{c} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \quad \text{CH}_2 \end{array} NEt$	8 mins.

From this it is evident that ethylenedipiperidine, which may be regarded as a normal tertiary diamine, is far less reactive than diethylpiperazine, in which the unsaturated nitrogen atoms are situated in the 1:4-position in the ring. Ethylenedipiperidine is assumed to be normal, since the refractive power, 61.05 [as observed both by Brühl (*Zeitsch. physikal. Chem.*, 1895, **16**, 316) and the present author], agrees closely with the value calculated from the refractive power of methylpiperidine—31.58—as determined by Brühl (*loc. cit.*), and evaluated by the Lorentz-Lorenz formula:

	M_a (obs.).	M_a (calc.).	Δ .
Ethylenedipiperidine			
$C_5H_{10}N \cdot C_2H_4 \cdot NC_5H_{10} \dots$		$2C_5H_{10}NMe \dots$ 63.16	
		Less $2H$	2.18
	61.05	60.98	+ 0.07

The values of the atomic refractions are taken from Eisenlohr's paper (*Zeitsch. physikal. Chem.*, 1910, 75, 585).

Further examples of piperazine derivatives were compared with the corresponding open-chain compounds:

FIG. 1.

		Time for 10 per cent. reaction.
isoAmyl piperidine	$C_5H_{10}N \cdot C_5H_{11}$	1 hr., 40 mins.
Dimethyldiisamylethylenediamine	$C_6H_{11} \cdot NMe \cdot C_3H_7 \cdot NMe \cdot C_5H_{11}$...	48 mins.
Diisamylpiperazine	$C_5H_{11}N \begin{array}{c} \diagup C_3H_7 \\ \diagdown C_2H_5 \end{array} NC_5H_{11}$	37 mins.
		Time for 10 per cent. reaction.
Benzylpiperidine	$C_5H_{10}N \cdot CH_2Ph$	5 hrs., 10 mins.
Dibenzyl dimethylethylenediamine	$CH_2Ph \cdot NMe \cdot C_2H_4 \cdot NMe \cdot CH_2Ph$	17 hrs., 10 mins.
Dibenzylpiperazine	$CH_2Ph \cdot N \begin{array}{c} \diagup C_2H_5 \\ \diagdown C_2H_5 \end{array} N \cdot CH_2Ph$	12 hrs., 40 mins.

In both these cases the piperazine derivative is observed to be more reactive than a corresponding dimethyl derivative of ethylenediamine.

Refractive powers of these pairs of compounds were measured, and it was found that in each case the piperazine derivative

FIG. 2.

FIG. 3.

AFFINITY AND CHEMICAL CONSTITUTION. PART II. 1931

exhibited a small but distinct exaltation, which is of the same order of magnitude as that observed for diethoxythioxan (+0.40).

	M _a (obs.).	M _a (calc.).	Δ.
Dimethyldiisocamylethylenediamine.....	74.12	—	—
Diisocamylpiperazine	72.46	71.64	+0.52
Dibenzylmethylethylenediamine	85.52	—	—
Dibenzylpiperazine	83.83	83.34	+0.49
	(mean of three observations)		

Benzylpiperidine was also examined, and the value 55.65 observed for the molecular refractive power.

The calculation of the refractive power of the piperazines from that of the open-chain compound is effected in the ordinary manner.

	M _a .
Value for dimethyldiisocamylethylenediamine.....	74.12
Less value for two hydrogen atoms	2.18
Calculated value for diisocamylpiperazine	71.94
Observed " " "	72.46
Difference	+0.52

It may be noted that the value observed for benzylpiperidine (55.65) is normal, there being only a slight difference from the value calculated from those of methylpiperidine and toluene:

	M _a .
Methylpiperidine	31.58
Toluene	30.79
	60.37
Less CH ₂ +2H	6.78
Benzylpiperidine (calc.).....	55.59
" (obs.)	55.65
Difference	+0.06

The refractive powers of the corresponding phenyl open-chain and piperazine derivatives were determined, and the observed values compared with that of dimethylaniline (Brühl, *Zeitsch. physikal. Chem.*, 1895, **16**, 220):

	M _a (obs.).	M _a (calc.)	Δ.
Dimethylaniline, NMe ₂ Ph.....	40.38	—	—
Diphenyldimethylethylenediamine, NMePh·CH ₂ ·CH ₂ ·NMePh.....	78.65 (mean of two observations)	78.58	+0.07
Diphenylpiperazine, PhN<math>\begin{matrix} \text{CH}_2\text{CH}_2 \\ \text{CH}_2\text{CH}_2 \end{matrix}>\text{NPh}...	77.52 (mean of two observations)	76.47	+1.05

apparently the bicyclic quaternary ammonium chloride; only a very small quantity of an oil being obtained, which boiled above 300° under atmospheric pressure, and was insufficient for further purification. The quaternary chloride was not isolated.

From the above results it may be assumed that the two nitrogen atoms in methylenedipiperidine affect each other by virtue of their situation on the same carbon atom, in a manner similar to that of the halogen compounds described in a previous communication. Ethylenedipiperidine, in which the nitrogen atoms are situated

FIG. 4.

relatively in the 1:4-positions in the chain, may be regarded as normal. In trimethylenedipiperidine the nitrogen atoms are in the critical 1:5-position, and may be assumed to come into close proximity during their possible oscillations. This compound exhibits a reactivity above that of ethylenedipiperidine, so that it may without doubt justly be inferred that the spacial proximity induces the increased reactivity. The abnormality may be regarded as of the same type as that evinced by the piperazines, while the high reactivity of methylenedipiperidine may be attributed to a different cause.

The refractive powers of the derivatives of piperidine were measured, the following values being obtained:

	M _n .
Methylenedipiperidine	56.30
Ethylenedipiperidine	61.05
Trimethylenedipiperidine	65.62

Taking ethylenedipiperidine as the standard, and deducting or adding the refraction of the methylene group (4.60), methylenedipiperidine appears to be slightly depressed (-0.15), whilst trimethylenedipiperidine is almost exactly normal (-0.03). Refractive power therefore tends to throw no further light on the exalted reactivity of trimethylenedipiperidine. The author intends to enter more fully into the phenomena of space conjugation in a study of compounds of sulphur.

EXPERIMENTAL.

Methylenedipiperidine.—Prepared by Kraut's method (*Annalen*, 1890, **258**, 109) from piperidine and the condensation product of formaldehyde and sodium hydrogen sulphite. B. p. 235°. D_4^{25} 0.9168, n_D^{25} 1.47903; whence $M_n = 56.30$.

Ethylenedipiperidine.—From ethylene bromide and piperidine. B. p. 263°. D_4^{25} 0.9236, n_D^{25} 1.48720; whence $M_n = 61.05$.

Trimethylenedipiperidine.—From trimethylene bromide and piperidine. B. p. 278° [Toll (*Ber.*, 1895, **28**, 2214) gives b. p. 274–275°]. D_4^{25} 0.9175, n_D^{25} 1.48520; whence $M_n = 65.62$.

s-Dimethyldiisomylethylenediamine.—Four molecular proportions of methylisoamylamine [prepared by Störmer and Lepel's method (*Ber.*, 1896, **29**, 2118) from isovaleraldehyde and methylamine, with subsequent reduction of the product] were treated in alcoholic solution under reflux with one molecular proportion of ethylene bromide in the presence of sodium acetate for four hours on the water-bath. After expelling the bulk of the alcohol and some unchanged methylisoamylamine by distillation on the water-bath, the product was treated with aqueous alkali, extracted with ether, and the ethereal extract fractionally distilled under diminished pressure. The pure product was obtained in good yield as a colourless oil, boiling at 130–131°/18 mm., insoluble in water, miscible with organic liquids, which rapidly absorbs carbon dioxide from the atmosphere, with formation of a solid product:

0.0826 gave 0.2222 CO₂ and 0.1050 H₂O. C=73.37; H=14.19.

C₁₄H₂₈N₂ requires C=73.68; H=14.03 per cent.

D_4^{25} 0.8083, n_D^{25} 1.43855; whence $M_n = 74.12$.

Diisomylpiperazine.—Equimolecular proportions of isoamylamine and ethylene bromide in alcoholic solution were warmed on the

water-bath under reflux for eight hours, with occasional addition of alcoholic potassium hydroxide in quantities just sufficient to remove ionisable bromine as a precipitate of potassium bromide. On completion of the reaction the mixture was filtered, the filtrate rendered faintly acid with hydrochloric acid, and the alcohol evaporated. The residue was dissolved in water, extracted with a small quantity of ether, then rendered strongly alkaline, and again extracted with ether. The ethereal solution, after being dried, was freed from ether, and the residue fractionally distilled under diminished pressure. The pure *diisocamylpiperazine* was obtained in poor yield as a colourless oil, boiling at $136\text{--}137^\circ/18\text{ mm.}$, insoluble in water, miscible with organic liquids, and strongly basic:

0.1048 gave 0.2840 CO_2 and 0.1273 H_2O . $\text{C}=73.91$; $\text{H}=13.49$.

$\text{C}_{14}\text{H}_{26}\text{N}_2$ requires $\text{C}=74.34$; $\text{H}=13.28$ per cent.

D_4^{20} 0.83603, n_D^{20} 1.44860; whence $M_n=72.46$.

Benzylpiperidine.—From benzyl chloride and piperidine. B. p. 245° . D_4^{18} 0.9625, n_D^{18} 1.52420; whence $M_n=55.65$.

s-Dibenzyltrimethylethylenediamine.—Four molecular proportions of benzylmethanamine were warmed for five hours on the water-bath under reflux with one molecular proportion of ethylene bromide in alcohol in presence of sodium acetate. The mixture was then filtered, the alcohol expelled on the water-bath, and the residue treated with concentrated aqueous sodium hydroxide and extracted with ether. The extract, after being dried, was freed from ether, and the residue distilled under diminished pressure. The fraction boiling above $195^\circ/10\text{ mm.}$ was collected separately, and redistilled, when the pure product was obtained as a pale yellow oil, boiling at $198^\circ/10\text{ mm.}$, insoluble in water, and miscible with organic liquids:

0.0981 gave 0.2902 CO_2 and 0.0804 H_2O . $\text{C}=80.67$; $\text{H}=9.16$.

$\text{C}_{18}\text{H}_{24}\text{N}_2$ requires $\text{C}=80.59$; $\text{H}=8.95$ per cent.

D_4^{18} 0.9717, n_D^{18} 1.53244; whence $M_n=85.52$.

Dibenzylpiperazine.—Two samples were prepared; one from benzyl chloride and piperazine, and one from ethylene bromide and benzylamine in presence of alcoholic potassium hydroxide. In both cases the product was distilled under diminished pressure, and then recrystallised from alcohol. It melts at 92° .

I.—In Alcohol.

Solvent: D_4^{18} 0.79982; n_D^{18} 1.36133; wt. 3.3497.

 $M_a = 77.63$.

Conclusions.

- (1) The nitrogen atoms in *N*-substituted piperazines exert a mutual influence, occasioning optical exaltation.
- (2) Tervalent nitrogen atoms in the "critical" positions in normal

chain compounds exert a similar mutual influence, but no optical anomaly has been detected in such substances.

(3) The reactivity towards organic halogen compounds of nitrogen atoms exerting such mutual influence is thereby increased.

The author desires to thank Dr. Smiles for valued advice and encouragement, and to express his gratitude to the Research Fund Committee of the Society for a grant in aid of the work.

CCXVIII.—*The Temperature-coefficient of the Electrical Conductivity of Hydrogen Chloride in Alcoholic Solution.*

By JAMES RIDDICK PARTINGTON.

IN a recent communication (Lapworth and Partington, this vol., p. 1417), the existing data for the conductivity of alcoholic hydrogen chloride were discussed, and it was remarked that the values of different observers were not in agreement. The conductivities at 25° were re-determined, and found to lie close to the values of Goldschmidt and Udby (*Zeitsch. Elektrochem.*, 1909, 15, 5), except at high dilutions, when they were consistently lower than the latter.

The value of λ_{∞} at 25° was fixed at 66.5.

The number 43.10, recorded by Baly, Burke, and Marsden (*Trans.*, 1909, 95, 1100) as the result of experiments at 15° (of which no details are given), together with the temperature-coefficient of Völlmer (*Ann. Physik*, 1894, [iii], 52, 328), leads to a value of λ_{∞} at 25° which is certainly considerably lower than any other recorded value. It was therefore thought desirable to determine the conductivities at 0° and 18° (these temperatures being more conveniently maintained than 15°) with the purpose of finding whether, possibly, there might be some abnormality in the temperature-coefficient, and also of obtaining data on the electrical relations of hydrogen chloride which will be required in further investigations now in progress in this laboratory.

The apparatus consisted of cells of three different sizes, with platinised platinum electrodes, and closed with carefully ground glass stoppers. The constants were determined at 25° by means

of $N/10$ -potassium chloride solution, the specific conductivity of which was taken as $k=0.01288$ mho.

Resistance measurements were made by means of a Nalder pattern Wheatstone bridge, with a small induction coil and telephone.

Alcoholic hydrogen chloride solutions were prepared and kept in the manner described in a previous communication (Trans., 1910, 99, 1420).

The cells were cleaned with nitric acid and distilled water, and then carefully dried in an air-oven before each measurement. They were filled as rapidly as possible from a pipette, quickly stoppered, and the stopper covered with Faraday cement. The filling and closing of the cell must not occupy more than half a minute, otherwise the entrance of atmospheric moisture vitiates the results. The leads were joined through stout rubber tubing to glass tubes with mercury connexions, which were sealed into the sides of the cell, so that the whole could be sunk in a thermostat (compare Partington, this vol., p. 470), or immersed in clean, pounded ice, as required. The solutions could be kept for several days in carefully closed flasks in full daylight without altering in conductivity, but if allowed to remain for a day in the cell (that is, in contact with platinum), their conductivities decreased, and the solutions gave the Schiff reaction for aldehydes (compare Cohen, *Zeitsch. physikal. Chem.*, 1898, 25, 1; Lapworth and Partington, this vol., pp. 1422, 1426). Measurements with solutions of very different concentrations, and extending over several hours, showed that steady values of the conductivity were reached after half an hour at 0° , and fifteen minutes at 18° ; with very dilute solutions the conductivities changed appreciably after about twelve hours. The cells were frequently shaken during the measurements.

In the tables below are given (I) the concentrations in gram-molecules per litre, (II) the observed resistances in ohms, (III) the cell constants, (IV) the molecular conductivities, (V) the values of the latter from the smoothed curves. The values of λ_∞ were obtained by the graphical method described in the previous communication. The values at the highest dilution were corrected for the conductivity of the specimen of alcohol used; for all other concentrations this correction was inappreciable.

λ_{∞} at 18° = 60.00 (extrapolated).

(All values marked with asterisks were rejected in calculating the mean values.)

These results, along with those at 25° recorded in the previous paper, are represented graphically in Fig. 1, where λ is plotted against the cube root of the concentration. The values of

Goldschmidt and Udby (G) at 25°, and of Baly, Burke, and Marsden (B) at 15°, are added for comparison. The latter values are evidently much too small, and their position with respect to the curves makes it probable that they contain a large constant

error—possibly some arithmetical inaccuracy in connexion with the cell-constant. As these observers give no details, it is not possible to hazard any more definite explanation of the discrepancy.

The Temperature-coefficient of λ_{∞} .

If we assume that the molecular conductivity is a linear function of temperature:

$$\lambda = \lambda_0(1 + \alpha\theta),$$

where θ = temperature Centigrade, α = temperature-coefficient, we find, from the three values:

$$(a) \lambda_{\infty} = 46.5 \text{ when } \theta = 0$$

$$(b) \lambda_{\infty} = 60.0 \quad \text{,,} \quad \theta = 18$$

$$(c) \lambda_{\infty} = 66.5 \quad \text{,,} \quad \theta = 25,$$

the following values of α_{∞} :

$$(a) \text{ and } (b) \alpha_{\infty} = 0.0185$$

$$(a) \text{ ,, } (c) \alpha_{\infty} = 0.0172$$

$$\therefore \text{Mean } \alpha_{\infty} = 0.0178.$$

Summary.

The conductivities of alcoholic solutions of hydrogen chloride have been determined at 0° and 18° . The results of these experiments, together with those of previous experiments at 25° , have led to the following values for the limiting molecular conductivities and the temperature-coefficient α of the latter:

$$\lambda_{\infty} \text{ at } 0^{\circ} = 46.50$$

$$\lambda_{\infty} \text{ ,, } 18^{\circ} = 60.00$$

$$\lambda_{\infty} \text{ ,, } 25^{\circ} = 66.50$$

$$\alpha_{\infty} (\text{mean}) = 0.0178.$$

In conclusion, the author desires to thank Dr. A. Lapworth for the interest he has taken in the progress of the research.

UNIVERSITY OF MANCHESTER.

CCXIX.—*The Absorption Spectra of the Nitration Products of Dimethyl-p-toluidine.*

By GILBERT T. MORGAN and ARTHUR CLAYTON.

IN continuance of their earlier investigations on the nitration of dimethyl-*p*-toluidine (Trans., 1905, 87, 947; 1910, 97, 2645), the authors have endeavoured to complete the series of nitro-derivatives of this tertiary base with the object of studying the effect of successive nitration on the colours and absorption spectra of these products.

Six of the nine theoretically possible nitro-derivatives of dimethyl-*p*-toluidine are known at present, together with several secondary nitration products (nitrosoamines and nitroamines), and an account

of the work is now put forward, inasmuch as the absorption spectra of polynitrated aromatic amines and their derivatives have not hitherto received much attention.

2:3:6-Trinitrodimethyl-*p*-toluidine (Formula VII).

A solution of one part of 2:6-dinitrodimethyl-*p*-toluidine in nine parts of concentrated sulphuric acid was diluted with fifteen parts of water, and the pasty mass thus produced treated with two to three parts of nitric acid (D 1.4), the mixture being heated at 95° for about ten minutes. The product, which was crystallised repeatedly from alcohol, separated in scarlet, flattened needles or plates, and melted at 137°:

0.1116 gave 0.1652 CO₂ and 0.0399 H₂O. C=40.37; H=3.97.

0.1005 „ 18.4 c.c. N₂ at 22° and 760 mm. N=20.75.

C₉H₁₀O₆N₄ requires C=40.00; H=3.70; N=20.74 per cent.

The constitution of 2:3:6-trinitrodimethyl-*p*-toluidine is sufficiently indicated by the preparation of the base from 2:6-dinitrodimethyl-*p*-toluidine (Trans, 1910, 97, 2645), as only one trinitro-derivative is theoretically possible.

2:3:6-Trinitro-*p*-tolylmethylnitrosoamine,

The action of highly concentrated nitric and sulphuric acids at high temperatures on the foregoing trinitro-base led to decomposition; milder treatment furnished the nitrosoamine with elimination of a methyl group from the tertiary amine radicle.

The pasty mass obtained by adding ten parts of water to the solution of one part of the trinitro-compound in nine parts of concentrated sulphuric acid was warmed for a short time at 80° with three parts of nitric acid (D 1.4), until the colour changed from red to yellow. The product was precipitated by ice-water, and crystallised from glacial acetic acid:

0.1403 gave 0.1751 CO₂ and 0.0366 H₂O. C=34.03; H=2.89.

0.0822 „ 17.3 c.c. N₂ at 19° and 766 mm. N=24.33.

C₈H₇O₇N₅ requires C=33.68; H=2.46; N=24.56 per cent.

2:3:6-Trinitro-*p*-tolylmethylnitrosoamine crystallises in yellow needles, melting at 162–163°, and giving the Liebermann reaction; it can also be prepared by heating the trinitro-base directly with a mixture of nitric acid (D 1.4) and 60 per cent. sulphuric acid.

2:5-Dinitro-p-tolylmethylnitrosoamine (Formula VIII).

A mixture of 2:5-dinitrodimethyl-*p*-toluidine (one part), 60 per cent. sulphuric acid (forty parts), and nitric acid (five parts, D 1.4) was heated for one hour at 100°, and the product crystallised from alcohol:

0.1672 gave 0.2460 CO₂ and 0.0596 H₂O. C=40.13; H=3.94.

0.1233 „ 25.0 c.c. N₂ at 18° and 760 mm. N=23.42.

C₈H₈O₅N₄ requires C=40.00; H=3.33; N=23.33 per cent.

2:5-Dinitro-*p*-tolylmethylnitrosoamine crystallises in pale yellow needles, melting at 126–127°; it is identical with one of the two nitrosoamines obtained by Pinnow from methyl-*p*-toluidine (*Ber.*, 1897, 30, 840).

Action of Nitric Acid on 3:5-Dinitrodimethyl-p-toluidine.—This dinitro-base, when treated with mixtures of concentrated nitric and sulphuric acids at temperatures below 80°, remained unchanged; at higher temperatures a methyl group was eliminated, often with extreme violence owing to the formation of explosive methyl nitrate. The only definite products were 3:5-dinitro-*p*-tolylmethylnitrosoamine (m. p. 128°; Formula IX; compare Romburgh, *Ber.*, 1896, 29, 1016) and the corresponding nitroamine. There was no indication of further nitration in the ring without elimination of a methyl group.

3:5-Dinitro-*p*-tolylmethylnitroamine (m. p. 138°; Formula X) was also prepared by the action of concentrated nitric acid (D 1.5) on the foregoing nitrosoamine (compare Gattermann, *Ber.*, 1885, 18, 1482; Romburgh, *loc. cit.*; and Reverdin, *J. pr. Chem.*, 1911, [ii], 83, 167).

Absorption Spectra.

The absorption spectra of the nitrated dimethyl-*p*-toluidines and nitrated *p*-tolylmethylnitrosoamines were examined in absolute alcoholic solutions. The source of light was an iron arc, and a quartz spectrograph of high dispersive power was employed.

2-Nitrodimethyl-*p*-toluidine (m. p. 37°; Formula I; compare *Trans.*, 1905, 87, 947) was compared with its isomeride, 3-nitrodimethyl-*p*-toluidine (m. p. 25°; Formula II; Pinnow, *Ber.*, 1895, 28, 3039), which was readily prepared in a solid form from its re-crystallised sulphate. The absorption of the latter base has already been described by Baly, Tuck, and Marsden (*Trans.*, 1910, 97, 581):

1944 MORGAN AND CLAYTON: THE ABSORPTION SPECTRA OF THE

The absorption curves of these two isomerides have the same general form, thus indicating similarity in constitution. The chief

FIG. 1.

Upper curves:

difference is that the absorption band of the ortho-nitroamine is nearer the red end (head of curve $1/\lambda$ 2290), and more persistent than the band ($1/\lambda$ 2560) of the meta-nitroamine:

2:5-Dinitrodimethyl-*p*-toluidine (Morgan and Clayton, *loc. cit.*), which contains its two nitro-groups unsymmetrically arranged with respect to the aminic radicle, shows an absorption band ($1/\lambda$ 2160) narrower than, but still comparable with, the bands exhibited by the two foregoing mononitro-bases. The remainder of the absorption curve (Fig. 1) departs from the form characteristic of aromatic mononitroamines in showing a very rapid change of absorption at certain dilutions, a step-out making its appearance at $1/\lambda$ 2820— $1/\lambda$ 3800.

2:6-Dinitrodimethyl-*p*-toluidine (Morgan and Clayton, *loc. cit.*) gives a curve differing very considerably from those of the foregoing nitrated amines, and also from those of all other aromatic nitroamines which have been previously studied (compare Baly, Tuck, and Marsden, *loc. cit.*). The absorption band (head $1/\lambda$ 2550) is broadened and flattened almost to extinction, the remainder of the curve being comparable with that of 2-nitrodimethyl-*p*-toluidine.

The 2:6-dinitro-base differs from the 2:5-dinitro-isomeride in containing its two nitro-groups symmetrically disposed with regard to the basic group, a fact which suggests that symmetry of the molecule may play an important part in diminishing the selective absorption exercised by the compound. This hypothesis is supported by the behaviour of 3:5-dinitrodimethyl-*p*-toluidine (m. p. 99—100°; Pinnow, *Ber.*, 1898, **31**, 2518). This base also contains its two nitro-groups in symmetrical positions with respect to the basic nitrogen, but in this instance they are both in ortho-, whereas in the former they are both in meta-positions. Since substituents in ortho-positions almost invariably affect each other more than when present in meta-positions, it is not surprising to find that the diminution of selective absorption attains its maximum in the case of 3:5-dinitrodimethyl-*p*-toluidine. The absorption band (Fig. 1) has disappeared, and is replaced by a step-out.

As it was not found possible to prepare 2:3-dinitrodimethyl-*p*-toluidine, the remaining isomeride of the above-mentioned bases, the corresponding 2:3-dinitromethyl-*p*-toluidine (Formula VI) was prepared and examined (Pinnow, *Ber.*, 1897, **30**, 833).

This comparison is quite justifiable, because Baly, Tuck, and Marsden (*loc. cit.*) have shown that in this group of nitro-compounds the mono- and di-methyl derivatives exhibit practically the same

absorption spectra, the only difference being that methylation shifts the absorption a little to the red:

The substitution of a nitro-group in 2:6-dinitrodimethyl-*p*-toluidine to form 2:3:6-trinitrodimethyl-*p*-toluidine (VII) introduces into the molecule an element of dissymmetry which is manifested in the absorption curve (Fig. 2) by the reappearance of the band ($1/\lambda$ 2280), which, however, is comparatively shallow.

In 2:3-dinitromethyl-*p*-toluidine (VI), where the substituents are arranged consecutively, the maximum amount of dissymmetry is produced, and the absorption curve indicates a band ($1/\lambda$ 2280) which is the most persistent of any exhibited by this series of nitrated amines.

An examination of the absorption spectra of 2:5-dinitro- and 3:5-dinitro-*p*-tolylmethylnitrosoamines shows, however, that this effect of dissymmetry is exhibited only when the basic aminic group is present in the molecule. This basicity is considerably diminished by the replacement of one methyl group by a nitroso- or nitro-radicle:

The absorption curves of 2:5-dinitro-*p*-tolylmethylnitrosoamine (VIII) and 3:5-dinitro-*p*-tolylmethylnitrosoamine (IX) indicate a very similar general absorption (Fig. 2), although the former compound contains its nitro-groups unsymmetrically arranged with regard to the aminic nitrogen, whilst the nitro-groups of the latter isomeride are disposed symmetrically in this respect.

3:5-Dinitro-*p*-tolylmethylnitroamine (X) when first discovered was regarded as a trinitromethyl-*p*-toluidine (Gattermann, *loc. cit.*), but its absorption curve is quite comparable with those of the foregoing nitrosoamines, thus furnishing spectroscopic evidence in support of Romburgh's observation that one of the three nitro-groups is attached to nitrogen (*Rec. trav. chim.*, 1882, **3**, 404).

The Colour of Aromatic Nitroamines.

The introduction of an amino-group into the benzene nucleus involves a complete change in the absorption spectrum of this

FIG. 2.
Upper curves :
Full curve — 3 : 5-Dinitro-monomethyl-p-toluidine.

hydrocarbon. The seven small bands of benzene disappear, and the new spectrum exhibits one broad, well-defined band in the ultra-violet (Baly and Collie, Trans., 1905, 87, 1343). The conversion

of colourless aniline into the yellow nitroanilines is not accompanied by any such marked alteration in the general character of the absorption, the change consisting mainly in a shift of the absorption band into the visible region of the spectrum, and in a persistence of the absorption at greater dilutions.

The question of relationship between the colour and constitution of henzenoid nitroamines is accordingly a special case of the general problem of the connexion between the selective absorption of aromatic bases and their chemical configuration.

It is customary to regard the nitro-group as the chromophor in nitroamines, but this effect is not specific, for other complexes play a similar part. In the aminocoumarins and their alkyl derivatives the unsaturated lactonic ring is the chromophor (Trans., 1904, 85, 1230; 1910, 87, 1350), and β -anthramine and di-*o*-aminostilbene exhibit colour in the absence of any substituent (*Annalen*, 1882, 212, 57; *Ber.*, 1895, 28, 1411).

The hypothesis that the colour of nitroanilines is due to a quinoid rearrangement of the molecule involving migration of hydrogen to the nitro-group, has been refuted by Baly, Tuck, and Marsden (*loc. cit.*), who showed that 3-nitro-*p*-toluidine and its methyl and dimethyl derivatives give absorption curves which are almost superposable, excepting that methylation shifts the band towards the red. Similar relationships were observed with the nitroanilines and their dialkyl derivatives.

With one nitro-group in the ring, variation in the orientation does not greatly modify the spectrum, but in general the band of the ortho- and para-derivatives is more persistent than that of the meta-isomeride.

As shown in the present communication, the effect produced by a second nitro-group depends largely on its position in relation to the aminic radicle and to the nitro-group already present. The question arises whether the exceptional form of the absorption curves of 2:6- and 3:5-dinitrodimethyl-*p*-toluidine is due to some alteration in the configuration of the aromatic nucleus consequent on the symmetrical grouping of the two nitro-groups about the basic radicle.

Kaufmann has suggested (*Ber.*, 1902, 35, 3668) that nitro- and amino-derivatives of benzene contain respectively the aromatic nucleus in centric and para-quinonoid conditions, the latter corresponding with Dewar's benzene formula. In accordance with this view, one might expect that increase in the number of nitro-groups would result in a change from the spectrum of the nitroanilines to that exhibited by nitrobenzene. But the absorption curve of

2:3:6-trinitrodimethyl-*p*-toluidine is nearer to the characteristic nitroamino-form than that of 2:6-dinitrodimethyl-*p*-toluidine.

Moreover, Hantzsch has compared the spectrum of 3:5-dinitroaniline with that of 5-nitro-1:3-phenylenediamine, a base having an equally symmetric molecule, but a preponderance of amino-groups. The two curves are very similar, the bands occurring nearly in the same region of the spectrum, but, on the other hand, these absorption spectra are entirely different from that of 1:3:5-trinitrobenzene, which has no absorption band (*Ber.*, 1910, **43**, 1669).

It seems reasonable to infer that, in so far as mono-, di-, and tri-nitroamines are concerned, any change in the aromatic nucleus which may result from successive nitration is not such as can be indicated by differences in structural formulae (compare Hartley, *Trans.*, 1885, **47**, 693). This conclusion has also been reached by Hantzsch (*loc. cit.*), who regards the nitroanilines and their alkyl derivatives as having the conventional formula, but with the nitro-groups linked by subsidiary valencies to the hydrogen or alkyl radicles of the amino-group.

The fact that the character of the absorption is altered completely by the saturation of the aminic group suggests, however, that the predominant factor is the residual affinity of basic nitrogen. The shift of the absorption into the visible region of the spectrum may be regarded as due to a chemical change of the nature of internal salt formation, since it is independent of the relative positions of the amino- and nitro-groups involved. When the residual affinity of the basic nitrogen is directed wholly towards one nitro-group or towards two contiguous nitro-groups, then the molecule becomes unevenly strained, and a well-defined absorption band is manifested. If, however, this residual affinity is divided between two similarly situated nitro-groups, then the atomic stresses may be supposed to be more evenly distributed in the molecule, with the result that less selective absorption takes place.

The authors desire to express their thanks to Dr. W. B. Tuck for his kind assistance in preparing the photographs and absorption curves, and to the Research Grant Committee of the Royal Society for a grant which has partly defrayed the expenses of this investigation.

CCXX.—*Decomposition of Hydrazides and Hydrazones by Heat.*

By FREDERICK DANIEL CHATTAWAY, CHARLES LINEAEUS CUMMING,
and BERNARD HOWELL WILSDON.

IN continuation of an investigation of the behaviour of hydrazines at a high temperature, the reactions which take place when various hydrazides and hydrazones are heated have been studied.

When a phthalylhydrazide is heated, vigorous action accompanied by the evolution of heat sets in at a definite temperature, nitrogen and ammonia are liberated, and a phthalanil is produced, thus:

When a hydrazone is heated, two main reactions take place, resulting in the formation of an unsaturated hydrocarbon, nitrogen, and a saturated hydrocarbon, thus:

and in the formation of an alkylideneaniline, nitrogen, and ammonia, thus:

The two reactions proceed simultaneously, a somewhat larger amount of the hydrazone as a rule undergoing the latter decomposition.

EXPERIMENTAL.

Decomposition of Phthalylphenylhydrazide by Heat.

Phthalylphenylhydrazide when crystallised from alcohol, which is the most convenient solvent to employ, is usually obtained as a mixture of two polymorphic modifications; the crystals of one are bright yellow, those of the other almost colourless. The yellow form is the one stable at temperatures near its melting point (180°), the colourless variety being transformed into the yellow form without melting before this temperature is reached.

One hundred grams of phthalylphenylhydrazide were melted, and heated slowly in an oil-bath. When the fused mass reached a temperature of about 346°, a vigorous reaction set in, accompanied by the evolution of heat and liberation of nitrogen and ammonia. This temperature was maintained until all action had ceased, when the viscous liquid remaining was distilled. The bulk of it passed over as an orange-yellow liquid, which solidified on cooling to a resin-like solid, a small quantity of coked residue being

left in the distilling flask. The solid distillate was recrystallised from alcohol and glacial acetic acid, and separated in fine, very pale yellow-coloured needles, melting at 208°.

From the mother liquors a small quantity of phthalimide was isolated.

The pale yellow, crystalline product, which formed practically the whole of the distillate, proved to be almost pure phthalanil, the colour being due to a very minute quantity of some yellow-coloured compound, probably a little of the original hydrazide which had escaped decomposition; this could be removed by boiling an alcoholic solution for a long time with animal charcoal, and repeated recrystallisation. A quantity carefully purified in this way melted sharply at 210°, and was identical in every respect with phthalanil made from phthalic anhydride and aniline, which also, when pure, melts at 210°. (Found, C=75.22; H=4.07; N=6.34; M.W.*=222.7. Calc., C=75.31; H=4.06; N=6.28 per cent. M.W.=223.)

The amounts of nitrogen and ammonia liberated were estimated by carrying out the decomposition of known quantities of the hydrazide in a current of carbon dioxide and hydrogen respectively; but owing to the time required to complete the decomposition, exact quantitative yields could not be obtained. The results, however, show conclusively that phthalylphenylhydrazide when heated decomposes thus:

Decomposition of Phthalyl-p-bromophenylhydrazide by Heat.

A similar reaction to that described above occurs when phthalyl-*p*-bromophenylhydrazide is heated, but owing to auto-reduction which goes on simultaneously, considerable quantities of hydrogen bromide are evolved. On distilling the solid product of the decomposition and recrystallising the distillate from alcohol, *p*-bromophthalanil was obtained, crystallising in fine needles (m. p. 204°), and identical with the compound obtained from phthalic anhydride and *p*-bromoaniline.

Decomposition of the Phthalyltolylhydrazides by Heat.

Only the deep yellow-coloured modifications of phthalyl-*o*- and -*p*-tolylhydrazide have up to the present been prepared, the exact conditions necessary for the deposition of the colourless modifications from solution not having yet been realised.

Phthalyl-*p*-tolylhydrazide behaves on heating exactly as does

* By determining the elevation of the boiling point of acetone.

phthalylphenylhydrazide. Twenty grams were similarly heated when at about 360° a vigorous reaction set in; heat as before was evolved, whilst nitrogen and ammonia were liberated. The yellow residue obtained when the action had completed itself was recrystallised from alcohol, and *p*-tolylphthalimide was obtained, crystallising in fine needles (m. p. 204°), and identical in every respect with the compound prepared by the interaction of phthalic anhydride and *p*-toluidine. Phthalyl-*o*-tolylhydrazide when heated behaved similarly, nitrogen and ammonia were given off, and *o*-tolylphthalimide could be isolated from the residue, but other subsidiary reactions which have not yet been investigated appeared to take place to a much greater extent than in the case of the para-compound.

Decomposition of Benzaldehydephenylhydrazone by Heat.

Benzaldehydephenylhydrazone (m. p. 156°) was placed in a small flask attached to a series of condensers, and gradually heated in an oil-bath. It commenced to decompose at about 210°, and at a temperature a few degrees higher a vigorous action took place, ammonia, nitrogen, and a liquid smelling strongly of benzene being produced. The liquid residue in the flask was heated until gas was no longer given off. The amounts of nitrogen and ammonia produced from weighed quantities of the hydrazone were determined by carrying out the decompositions in a current of carbon dioxide or of hydrogen. The liquid distillate was fractionated, and found to consist of benzene mixed with a very little toluene. The residue after all gas evolution had ceased was fractionally distilled in a vacuum. The lower fractions on cooling solidified to a white, crystalline mass, which on recrystallising from alcohol proved to be stilbene. It crystallised in white, glistening plates, which melted at 124°, and had the peculiar characteristic odour of the hydrocarbon. To complete the identification it was converted into the dibromide, which melted at 237°.

The fractions of higher boiling point which only slowly solidified proved to be benzylideneaniline, $C_6H_5 \cdot CH : N \cdot C_6H_5$.

Benzaldehydephenylhydrazone, therefore, when heated decomposes in two different ways. In one decomposition, stilbene, nitrogen, and benzene are produced, thus:

a reaction recalling the behaviour of benzylideneazine when heated.

In the other, benzylideneaniline, nitrogen, and ammonia are formed, thus:

a reaction similar to that which the phthalylhydrazides undergo

when heated. The greater part of the benzaldehydephenylhydrazones decomposes in the latter manner.

The small amount of toluene found is, without doubt, formed by the reduction of the benzyldene group by the hydrazine group, a little diphenyl, which could not be recognised in presence of the stilbene, being possibly also produced.

Decomposition of Benzaldehydetolyhydrazones by Heat.

Benzaldehyde-*p*-tolylhydrazone melts at 120° to a red liquid, which at about 190° decomposes, with evolution of heat, nitrogen, ammonia, and a small amount of toluene being liberated. After the evolution of gas has ceased, if the residual liquid is distilled, a yellow, viscid, oily substance passes over, which on cooling deposits crystals of stilbene. The oily liquid which can be filtered from them is benzyldene-*p*-toluidine, and yields benzaldehyde and *p*-toluidine when hydrolysed by dilute sulphuric acid.

Benzaldehyde-*p*-tolylhydrazone therefore decomposes in a precisely similar manner to benzaldehydephenylhydrazone when heated. The greater part decomposes into benzyldene-*p*-toluidine, nitrogen, and ammonia, thus:

while a considerable but smaller fraction yields stilbene, nitrogen, and toluene, thus:

Benzaldehyde-*o*-tolylhydrazone decomposes similarly when heated.

OXFORD.

CCXXI.—*The Absorption Spectra of Triketohydrindene Hydrate and Certain Derivatives.*

By JOHN EDWARD PURVIS.

THE absorption spectra of a series of coloured diketopyrrolines have been described and discussed by the author (Trans., 1910, **97**, 2535), and also of some derivatives and isomerides of 1:2-diketo-Δ³-cyclopentene (this vol., p. 107).

A series of coloured substances has been described by Ruhemann (Trans., 1910, **97**, 1438; this vol., p. 1486), and obtained from triketohydrindene hydrate, $\text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\rangle\text{C}(\text{OH})_2$, which from its

chemical behaviour was found to resemble alloxan very closely. These substances have been studied spectroscopically by the author in order to see how far the colour and absorption is connected (1) with the ketonic constitution, and (2) how far the colour and absorption are modified when the oxygen of the ketonic groups is replaced by other radicle groups. From chemical considerations, Ruhemann ascribed the following constitutional formulæ to the various compounds:

A. Triketohydrindene hydrate, $\text{C}_6\text{H}_4 \begin{smallmatrix} \diagup \text{CO} \\ \diagdown \text{CO} \end{smallmatrix} \text{C}(\text{OH})_2$, colourless.

B. Diphenylhydrazone of triketohydrindene, $\begin{smallmatrix} \text{C}_6\text{H}_5 \cdot \text{C} \cdot \text{N} \cdot \text{NHPh} \\ \text{CO} - \text{C} \cdot \text{N} \cdot \text{NHPh} \end{smallmatrix}$, red.

C. The hydrate of 2:3-bis-(*p*-dimethylaminoanilo)- α -hydrindone, $\begin{smallmatrix} \text{C}_6\text{H}_4 \cdot \text{C} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{NMe}_2 \\ \text{CO} - \text{C} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{NMe}_2 \end{smallmatrix}$, H_2O , very dark purple.

D. Ketohydrindenophenazine, $\begin{smallmatrix} \text{C}_6\text{H}_4 \cdot \text{C} \cdot \text{N} \\ \text{CO} - \text{C} \cdot \text{N} \end{smallmatrix} > \text{C}_6\text{H}_4$, canary-yellow.

E. 2-*o*-Carboxybenzoylindonoglyoxaline,

carmine-red.

F. 1:3-Diketohydrindamine, $\text{C}_6\text{H}_4 \begin{smallmatrix} \diagup \text{CO} \\ \diagdown \text{CO} \end{smallmatrix} \text{CH} \cdot \text{NH}_2$, yellow; this substance was not obtained very pure, as it rapidly decomposed.

G. 1:3-Diketo-2-benzylidenehydrindamine,

dull orange.

H. 1:3-Diketo-2-anisylidenehydrindamine,

vermillion-orange.

I. 1:3-Diketo-2-*p*-dimethylaminobenzylidenehydrindamine,

maroon or very dark red.

K. Diketohydrindylidenediketohydrindamine,

deep red.

L. The ammonium salt of K,

deep red.

TRIKETOHYDRINDENE HYDRATE AND CERTAIN DERIVATIVES. 1955

The substances *A*, *B*, *C*, *D*, and *E* were stable in absolute alcohol, although they differed greatly in their relative solubilities. The substances *G*, *H*, *I*, *K*, and *L* were very unstable in alcohol, but they were more stable in glacial acetic acid, and they were investigated when dissolved in that acid. The substance *F* decomposes so rapidly that no observations could be taken. Solutions of the various substances in milligram-molecules by weight were dissolved either in cold absolute alcohol or in glacial acetic acid, and their absorption spectra were examined photographically in the usual way, using Wratten and Wainwright's pan-chromatic plates. For example, *M*/100-solution means that one milligram-molecule by weight of the substance was dissolved in 100 c.c. of cold absolute alcohol or of glacial acetic acid, and this was further diluted so that 1000 c.c. contained one milligram-molecule by weight or *M*/1000-strength; and this again was diluted, so that it became *M*/10,000-strength. The absorption curves of the various solutions have been drawn. It will be seen that the colourless compound *A* has a well-marked band in *M*/100-solution (Fig. 1), the position of which is near the more refrangible end of the visible spectrum. The head of this band is at about 2800 (oscillation frequencies). *M*/1000-Solutions were also examined, but no other band was observed. The positions, the general absorption of which began through the following thicknesses of *M*/1000-solutions, were:

	λ .	$1/\lambda$.
3 mm. thickness	2480	4031
10 " "	2655	3765
30 " "	2775	3603
60 " "	2995	3358

The substance *B*, the red diphenylhydrazone of triketohydrindene, was examined in *M*/10,000-solution, and showed two bands, the curves of which have been drawn (Fig. 1, II). The heads of these two bands are at 2800 and 1980. The more refrangible band, 2800, corresponds with the band found in triketohydrindene.

The substance *C*, a very dark purple, almost black, compound, which gives a very dark purple solution, was also investigated in a *M*/10,000-solution. When examined through a thickness of 24 mm. the solution was so dark that little or no light passed through. It will be seen from the curve (Fig. 1, III) that the two bands of the *B* compound have been fused into one large, not very persistent band, the head of which is at about 1900.

The general effect, therefore, of the substitution of the oxygen of two of the ketonic groups of the colourless compound *A* by complex aromatic nitrogen compounds is to damp the vibrations so that there is absorption of light within the visible regions of the

spectrum, and a characteristic colour is produced. The substances *D* and *E* were also examined, but in neither case was a band observed. The positions when general absorption began through

FIG. 1.

Oscillation frequencies.

- I. Alcoholic solution of triketohydrindene hydrate (A).

the following thicknesses of *M*/10,000-alcoholic solutions of the substance *D* were:

	λ .	$1/\lambda$.
9 mm. thickness	3080	3244
30 " "	3300	3028
61 " "	3510	2848
90 " "	3930	2543
135 " "	4200	2380

The positions when general absorption began through the following thicknesses of *M*/10,000-alcoholic solution of the substance *E* were:

	λ .	$1/\lambda$.
9 mm. thickness	2780	3595
30 " "	3580	2791
51 " "	3780	2644
90 " "	3830	2576
134 " "	4125	2433
146 " "	4150	2409

Stronger solutions of *D* and *E* were not obtained, as the substances were not easily soluble.

The explanation of these phenomena appears to be that the

FIG. 2.

Oscillation frequencies.

establishment of another ring in each of these compounds has destroyed the selective absorption exhibited by the compounds *A*, *B*, and *C*, and that the colour is produced by an extension of the general absorption within the regions of the visible parts of the spectrum.

The coloured compounds *G*, *H*, and *I* were examined in $M/1000$ -solutions of glacial acetic acid, and the absorption curve of the band of each substance has been drawn (Fig. 2). It is evident from a study of these curves that the bands are all of the same type. The differences correspond with differences in the

shades of colour of the different compounds. For example, the substance *G* is a dull orange colour; the substance *H* a vermilion-orange; and the substance *I* is a maroon or a very dark red. The position of the bands, as well as their extension, illustrates these differences in shades of colour. The head of the band *G* is at about 2300; that of *H* is at about 2300, but is much wider than *G*; and that of *I* is about 2000. *M*/10,000-Solutions in glacial acetic acid were also examined through varying thicknesses, but no bands were observed in the ultra-violet regions.

FIG. 3.

Oscillation frequencies.

- I. Acetic acid solution of diketohydrindylidenediketohydrindamine (K).
- II. " " the ammonium salt of diketohydrindylidenediketohydrindamine (L).

The substances *K* and *L* were also examined in *M*/1000-solutions of glacial acetic acid, and the absorption curve of each has been drawn (Fig. 3). Here, again, the bands are evidently of the same type, and the differences correspond with differences in the shades of colour, which are both dark purple-brown. The curve of the ammonium compound (*L*) is not so persistent as that of the parent substance (*K*). The head of the band of *K*' is at about 1990, and that of *L* at about 2000. *M*/10,000-Solutions in acetic acid were also examined through varying thicknesses, but no bands were

TRIKETOHYDRINDENE HYDRATE AND CERTAIN DERIVATIVES. 1959

observed in the ultra-violet regions. The positions where general absorption began in $M/10,000$ -solutions were:

		λ .	$1/\lambda$.
K.	10 mm. thickness	2810	3556
	2 " "	2490	4014
L.	10 " "	2700	3702
	2 " "	2465	4054

So that the general effect of the substitution of oxygen in one of the ketonic groups of the colourless compound *A*, by complex aromatic compounds, is to damp the vibrations so that there is a selective absorption of light within the visible regions of the spectrum, and a characteristic colour is produced.

General Conclusions.

The results of the observations show that (1) the colour of the compounds is intimately connected with the presence of ketonic groups, phenomena which are analogous to those of the diketopyrrolines and the cyclopentenones (*loc. cit.*); (2) the shade of colour is modified according to the type of the substituting groups; (3) where another ring is established, as in the compounds *D* and *E*, there is no selective absorption, and the colour is produced by an extension of the general absorption within the regions of the visible spectrum.

It is important to refer to the observations of Hartley (*Trans.*, 1887, **51**, 154; 1905, **87**, 1791 *et seq.*), in which he shows that the colourless alloxan and uramil have no absorption bands, whereas the coloured murexide has two, the heads of which are at about 3300 and 1900; that is, the former, a weak band, is in the ultra-violet, and the latter, a strong and persistent one, is in the visible parts of the spectrum. These three compounds are constitutionally comparable with the compounds *A*, *F*, and *L* respectively. The comparison may be further extended in that the parent substance *A* (triketohydrindene hydrate) has no colour, although it exhibits an absorption band just beyond the visible part of the spectrum; the unstable substance *F* (1:3-diketohydrindamine) would probably show a similar band; and the coloured substance *L* (the ammonium salt of diketohydrindylidenediketohydrindamine) exhibits a band in the visible regions of the spectrum.

Apart from this comparison, it is also clear that selective absorption need not accompany the phenomenon of colour, as the author has shown in the isomerides of cyclopentene (*loc. cit.*); and the observation is confirmed by the coloured compounds *D* and *E* of this investigation, where no selective absorption was found.

Although there is no selective absorption, it is probable that the colour is the result of the transmission of rays between definite regions, the limit of which, in one direction, extends into the infra-red; and there is every possibility that such compounds would show selective absorption in these regions.

I have again to thank the Government Grant Committee of the Royal Society, by whose assistance the spectroscope was obtained; and also Dr. Rubemann for pure specimens of the substances examined.

UNIVERSITY CHEMICAL LABORATORY,
CAMBRIDGE.

CCXXII.—*The Alkaline Condensations of Nitro-hydrazo-compounds. Part I.*

By ARTHUR GEORGE GREEN and ERNEST ARTHUR BEARDER.

IN a series of researches on the constitution of the stilbene dyestuffs conducted by Green and former collaborators (Trans., 1904, 85, 1424, 1432; 1906, 89, 1602; 1907, 91, 2076; 1908, 98, 1721), it has been shown that the production of azostilbene compounds, whether by alkaline condensation of derivatives of *p*-nitrotoluene or by alkaline reduction of derivatives of 4:4'-dinitrostilbene, is preceded by the formation of unstable intermediate products, to which the constitution of nitrostilbenes was assigned.

In view of the parallelism between the $\cdot\text{N}:\text{N}\cdot$ and $\cdot\text{CH}:\text{CH}\cdot$ series which is exhibited in the following, amongst other, reactions:

it seemed not improbable that condensations might occur in the azo-series similar to those which give rise to the stilbene dyestuffs. It has long been known that by partial reduction of 4:4'-dinitroazobenzene a product is obtained which dissolves in alkali hydroxides with an intense blue colour, and it appeared possible that an analogy might exist between this product and the above-mentioned intermediate compounds of the stilbene class, which dissolve in alkalis with a crimson to blue colour. This anticipation was strengthened when we found that the former substance exhibited

its general behaviour a remarkable similarity to the latter class of compounds. Thus, in alkaline solution both are readily decolorised by air, the former yielding dinitroazobenzene, the latter dinitrostilbene. On heating their alkaline solutions, both are finally converted into stable yellow condensation products, which dissolve in concentrated sulphuric acid with a similar cherry-red colour. Further, in both cases these stable condensation products are converted by alkaline reducing agents into other products dissolving in concentrated sulphuric acid with a blue colour.

Assuming that the intermediate products of the stilbene condensation are correctly regarded as nitroso-compounds, the existence of a series of parallel condensations in the azo-class would necessitate the conclusion, either that the above reduction product of dinitroazobenzene, which is usually regarded as dinitrohydrazobenzene, is actually a nitroso-compound, or that such a nitroso-compound is formed in an early stage of its alkaline condensation. The present research has been undertaken with the object of investigating these questions, and, incidentally, of obtaining further light on the course of the stilbene reactions.

The product of the partial reduction of 4:4'-dinitroazobenzene, which dissolves with a bright blue colour in aqueous alkalis, has already been the subject of frequent investigations, which have led to very divergent views as to its constitution. It was discovered by Lermontoff in 1872 (*Ber.*, 1872, 5, 232), who regarded it as a dinitrohydrazobenzene, $N_2H_2(C_6H_4 \cdot NO_2)_2$, a conclusion which was strongly supported later by the work of Werner and Stiasny (*Ber.*, 1899, 32, 3272). On the other hand, Janovsky (*Monatsh.*, 1885, 6, 160), whose analytical results differ widely from those of other authors, ascribes to the compound the constitution of a nitrolic acid, $NO_2 \cdot C_6H_4 \cdot N_2 \cdot C_6H_4 \cdot N(OH) \cdot N(OH) \cdot C_6H_4 \cdot N_2 \cdot C_6H_4 \cdot NO_2$. Willgerodt (*J. pr. Chem.*, 1890, [ii], 42, 51) regards it as an "az-hydroxyazo" compound, $NO_2 \cdot C_6H_4 \cdot N_2 \cdot C_6H_4 \cdot NH(OH) \cdot O$; whilst Freundler and Beranger (*Compt. rend.*, 1902, 134, 1219) support the quinonoid formula: $HO_2N \cdot C_6H_4 \cdot N \cdot N \cdot C_6H_4 \cdot NO_2H$. Another possible structure hitherto unconsidered is that of a hydrated dinitrosoazobenzene, $(HO)_2N \cdot C_6H_4 \cdot N_2 \cdot C_6H_4 \cdot N(OH)_2$.

The preparation of this product at first offered some difficulties, owing to the absence of details in the published accounts, but it was finally obtained in a pure state and in good yield by reduction with colourless ammonium sulphide. When crystallised from acetone it had the characteristic crystalline form described by Janovsky, and after drying at 140° it melted (if heated quickly) at 228° , as given by Werner and Stiasny. The great variation in melting point observed by different investigators (L., 220° ; J., 218° ;

W., 248—250°; W. and S., 228°), which at first sight seems to suggest that they had varying products in hand, is more probably to be referred to the different rate of heating. The nitrogen value obtained for the compound agreed exactly with a dinitrohydrazobenzene, although it also approximated to the figure required for the hydrated dinitrosoazobenzene. On oxidising the blue alkaline solution by shaking with air or by addition of iodine, dinitroazobenzene was regenerated. Titration of the alkaline solution with a standard solution of iodine until complete disappearance of the blue colour, gave results which indicated the removal of two atoms of hydrogen. Titration of the acetic acid solution with titanium trichloride also gave figures in agreement with the dinitrohydrazobenzene formula, and this was further supported by the behaviour of the compound with acetic anhydride. When heated with this reagent for a short time only it remained unaltered, whereas if it were a hydrated form of dinitrosoazobenzene, or had the "az-hydroxyazo" formula suggested by Willgerodt, it should lose the elements of water. When boiled with a large excess of acetic anhydride for two hours it was converted into a diacetyl derivative, melting at 188—189°, which is doubtless identical with the dinitrodiacetylhydrazobenzene (m. p. 186—187°) obtained by Freundler and Beranger by nitration of diacetylhydrazobenzene. There is thus no reason to doubt the correctness of the conclusion arrived at by Werner and Stiasny, that the reduction product is actually dinitrohydrazobenzene.

The question next arises whether the blue colour of the alkaline solution is due to the formation of a salt of dinitrohydrazobenzene or whether a molecular change occurs under the influence of the alkali.

To ascertain this, a series of experiments was conducted, in which weighed quantities of the dinitrohydrazobenzene were dissolved in cold aqueous sodium hydroxide (10 to 20 per cent. NaOH), and then filtered into aqueous acid, both solution and filtration being effected in an apparatus from which air was completely excluded by means of hydrogen. If intermolecular oxidation and reduction occurred, it was to be expected that a precipitate of dinitroazobenzene would be produced. The dinitrohydrazobenzene dissolved completely, and the deep blue liquid, when not allowed to remain for more than fifteen minutes, left no appreciable precipitate on the filter. We further found that the freshly prepared blue solution gave when immediately acidified a light yellow precipitate of unaltered dinitrohydrazobenzene. It must therefore be concluded that the blue compound actually represents an alkali salt of dinitrohydrazobenzene, and if its entirely different colour and

much greater oxidisability in comparison with the free compound be considered, the assumption seems justified that the latter is a pseudo-acid, giving rise to salts of the quinonoid type,

This conclusion is also in agreement with the work of Grandmougin and Leeman (*Ber.*, 1906, **39**, 4384; 1908, **41**, 1295), who have isolated a blue dipotassium salt of hexanitrohydrazobenzene,

In the course of the above experiments it was observed that if the blue solution in aqueous sodium hydroxide (10 per cent. NaOH) is kept with exclusion of air for several hours, the colour becomes slightly more violet, whilst a small precipitation of dinitroazobenzene occurs. If the blue solution is now acidified, the precipitate has a much more orange colour than previously, is more voluminous, and is completely soluble in cold glacial acetic acid, in which dinitrohydrazobenzene scarcely dissolves at all. It also exhibits a much greater solubility in alcohol and in ether. In aqueous sodium hydroxide it dissolves readily with the same blue colour as dinitrohydrazobenzene, but, on the other hand, dissolves in sulphuric acid with a reddish-orange colour, in contrast to the pure yellow of the latter. When dry it forms a brick-red, amorphous powder, which could not be obtained crystalline. Analysis of this product gave numbers for carbon, hydrogen, and nitrogen conforming to dinitrohydrazobenzene, with which the results of titration with titanium trichloride were also in correspondence. If boiled, however, with acetic anhydride under conditions in which dinitrohydrazobenzene is quantitatively converted into the diacetyl derivative, the product in question gave rise to dinitroazobenzene (yield of about 70 per cent.). These results appeared at first sight to indicate that we had in hand a compound isomeric with the original dinitrohydrazobenzene. Such a supposition was, however, very difficult to express by any probable formula, and doubts arose as to its validity when it was found possible by repeated crystallisation from acetone to separate from the product a small quantity of pure dinitrohydrazobenzene. Subsequent experiments proved that the substance was in fact a mixture consisting of about four-fifths of unaltered dinitrohydrazobenzene with about one-fifth of a new compound. The latter was obtained pure by effecting the conversion with weaker alkali (3 per cent. NaOH), and allowing the solution to remain at the summer temperature (about 25°) for from six to sixteen hours. A violet-blue solution was thus produced, in which was suspended a considerable amount of dinitroazobenzene. After filtration from the latter the blue solution was acidified with acetic acid, which produced a very voluminous, colloidal, orange-red

precipitate. By rapid crystallisation from acetone the new compound was obtained in small, red cubes with a violet reflex. In concentrated sulphuric acid it dissolved with a pure crimson colour, which on addition of a drop of dilute nitric acid was changed to yellow (formation of dinitroazobenzene). It dissolved in alkali hydroxides to a violet-blue solution, which, like that of dinitrohydrazobenzene, is decolorised by air or iodine. A determination of the relative quantities of the new compound and of dinitroazobenzene produced from a given weight of dinitrohydrazobenzene gave results in agreement with the supposition that the reaction proceeds according to one or other of the two following equations:

The estimation of carbon, hydrogen, and nitrogen, and the results obtained by titration with titanium trichloride, establish for the compound the constitution $\text{C}_{12}\text{H}_{10}\text{O}_3\text{N}_4$; it is therefore formed in accordance with the first equation. The substance is therefore either a 4-nitro-4'-nitrosohydrazobenzene,

or a hydrated 4:4'-dinitrosoazobenzene,

As, however, the titration of the alkaline solution with standard iodine indicates the loss of two atoms of hydrogen in a similar manner to dinitrohydrazobenzene, the first of these formulæ appears the more probable.

Accepting the conclusion that the free compound is nitronitrosohydrazobenzene, it is probable that its violet-blue alkaline solutions contain quinonoid salts of the constitution

These salts should be identical with the oxime corresponding with the red alkaline salts of *p*-nitrobenzeneazophenol, to which Hewitt assigns the formula $\text{M}'\text{O} \cdot \text{ON} : \text{C}_6\text{H}_4 : \text{N} \cdot \text{N} : \text{C}_6\text{H}_4 : \text{O}$. Attempts to prepare the former by the action of hydroxylamine on the latter have not, however, been successful.

In respect to the incomplete action of cold alkali hydroxides on dinitrohydrazobenzene, it was found by direct experiment that a mixture composed of one part of nitronitrosohydrazobenzene and four parts of dinitrohydrazobenzene, when precipitated together, exhibited exactly the same properties as the product at first supposed to be an isomeric dinitrohydrazobenzene. The orange colour in sulphuric acid, its colloidal properties, and much greater solubility in solvents are therefore all due to the admixture of

nitronitrosohydrazobenzene. The different behaviour of the product with acetic anhydride appears also to be referable to the same cause, for the nitroso-compound on account of its greater reducibility may effect oxidation of dinitrohydrazobenzene to dinitroazobenzene before acetylation can occur.

As mentioned above, the final product of the action of alkali hydroxides on dinitrohydrazobenzene is very analogous to the final product of the stilbene condensation. It was obtained by heating the solution of nitronitrosohydrazobenzene in 3 per cent. sodium hydroxide to 100° until complete disappearance of the blue colour (air being rigidly excluded). The orange-coloured precipitate, after crystallisation from xylene, was obtained in sparingly soluble, orange needles, melting at 285–286°. Analysis supported the constitution:

The compound is therefore a *bisnitrobenzeneazo-azobenzene*, and owes its formation to the condensation of two molecules of nitronitrosohydrazobenzene, in accordance with the scheme:

In preparing the compound it is not necessary to employ the isolated nitronitrosohydrazobenzene, but the blue alkaline solution of dinitrohydrazobenzene may be heated at once to 100° until the blue colour disappears. The orange precipitate then obtained is a mixture of bisnitrobenzeneazo-azobenzene with dinitroazobenzene, and can be readily separated by solvents, in which the former compound is much less soluble. A quantitative determination of the yield of the two products agreed with the equation:

It was further found that the condensation of nitronitrosohydrazobenzene to bisnitrobenzeneazo-azobenzene can also be effected by merely boiling the former with neutral solvents.

The above experiments fully justify our original expectation of the existence of a parallelism between the derivatives of dinitroazobenzene and those of dinitrostilbene. If this analogy is complete it would seem to suggest that the intermediate products of the stilbene reaction are not, as hitherto believed, dinitrostilbenes, $\text{NO} \cdot \text{C}_6\text{H}_4 \cdot \text{CH} : \text{CH} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}$, but rather nitronitrosodibenzyls,

from which the final condensation products (stilbene dyestuffs) are formed in the manner indicated above for bisnitrobenzeneazo-azo-

benzene. The mobility of the two methylene hydrogen atoms may very probably be connected with the tendency to form quinonoid salts. The chief difficulty in this view lies in the fact that coloured (blue?) quinonoid salts of dinitrodibenzyl,

corresponding with the blue quinonoid salts of dinitrohydrazobenzene, have hitherto not been observed. The dinitrodibenzyl salts and those of its derivatives which have been investigated all give no colour with alkali hydroxides, except on heating. It is, however, possible that owing to the firmer attachment of hydrogen to carbon compared with that of hydrogen to nitrogen, the formation of quinonoid salts may take place with greater difficulty, or only at temperatures at which conversion into the nitronitroso-compound follows immediately. This is supported to some extent by the observation made by Green and Wahl, that dinitrodibenzyl-disulphonic acid when heated with sodium hydroxide is converted, in the first instance, into a mixture of dinitrostilbenedisulphonic acid with the crimson intermediate product. If the latter is nitronitrosodibenzyl-disulphonic acid, the reaction is exactly analogous to the above-described formation of dinitroazobenzene and nitronitrosohydrazobenzene from two molecular proportions of dinitrohydrazobenzene, and just as in this case may be preceded and conditioned by the prior formation of a quinonoid salt.

EXPERIMENTAL.

4:4'-Dinitroazobenzene.

This compound was prepared both by nitration of azobenzene and by oxidation of *p*-nitroaniline with calcium hypochlorite, identical products being obtained in both cases. The latter method, by which the pure product can readily be obtained in quantity, was that finally adopted. In conformity with Meigen and Normann (*Ber.*, 1900, 33, 2711), we found that the product of this reaction is the azo- and not the azoxy-compound. The operation is best conducted in the following manner: One hundred grams of *p*-nitroaniline are dissolved in a mixture of hydrochloric acid and hot water, filtered through glass wool, and poured into about 2½ litres of cold water, the base being thus obtained in a fine state of division. The mixture is then rendered alkaline with sodium hydroxide, and a clear solution of calcium hypochlorite added, containing about 50 per cent. more chlorine than that theoretically required. After stirring for about six hours and leaving overnight, the orange precipitate is collected, washed well with cold water, and then without drying extracted on the filter with cold acetone,

in order to remove unaltered *p*-nitroaniline and dark-coloured by-products. The residue is recrystallised from boiling xylene, from which it separates in long, orange-red leaflets, melting at 222–223°. To facilitate the subsequent reduction, it was found very advantageous to convert the product into a fine state of division by dissolving it in cold concentrated sulphuric acid, and pouring into water. In this case it is not necessary to crystallise from xylene, and the purification with acetone may be conveniently replaced by an extraction with cold dilute hydrochloric acid to remove *p*-nitroaniline, calcium carbonate, and other impurities. (Found, $N=20.87$. Calc., $N=20.59$ per cent.)

4:4'-Dinitrohydrazobenzene, $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2$.

After a number of experiments with various alkaline reducing agents, such as zinc dust and sodium hydroxide, dextrose and alkali, sodium sulphide, yellow ammonium sulphide, etc., none of which gave good results, the following method of preparation with colourless ammonium sulphide was adopted. The reagent was prepared just before use by saturating a mixture of equal parts of concentrated aqueous ammonia and water with hydrogen sulphide. Eleven grams of finely divided dinitroazobenzene are mixed in a mortar to a uniform paste with 150 c.c. of 95 per cent. alcohol, to which a few c.c. of acetone are added. The paste is transferred to a flask, heated to boiling, and 100 c.c. of the above aqueous ammonium sulphide are brought in. An immediate reaction occurs, and after about two minutes' boiling an equal volume of cold water is added. After cooling, the yellow precipitate is collected, washed with hot water, and then with alcohol, after which it is extracted with chloroform to remove any sulphur that may be present. The product is then dissolved in about 300 c.c. of boiling acetone (to which a little alcohol is added), and on cooling dinitrohydrazobenzene separates in pale yellow, transparent, rhombic prisms. The product on drying at 140° loses acetone, becoming opaque and of a deeper yellow colour. The yield was 6 or 7 grams. The product dried at 140° was found to melt at 228° if heated quickly, but on slower heating it melted at various other temperatures up to 250°. (Found, $N=20.4$. Calc., $N=20.4$ per cent.)

Reduction in acetic acid solution with standard titanium trichloride, titrating back the excess with ferric alum, gave the following result:

Hydrogen used = 5.08, 5.27, 5.17.

Hydrogen theoretically necessary for reduction of dinitrohydrazobenzene to *p*-phenylenediamine = 5.11 per cent.

In order to estimate the quantity of oxygen required to effect

decolorisation of the alkaline solution, titration with standard iodine in an atmosphere of hydrogen was employed. The end-point, indicated by the disappearance of the blue colour, is sharply defined. To secure rapid solution of the dinitrohydrazobenzene in the dilute sodium hydroxide employed and thus avoid any condensation, it was found advisable previously to dissolve the compound in acetone, reprecipitate with water, and wash thoroughly until every trace of acetone was removed. The fine precipitate was then transferred to a closed flask with 50 c.c. of water, the air displaced by hydrogen, and 50 c.c. of 6 per cent. sodium hydroxide were introduced from a tap funnel. Titration is then effected with $N/20$ -iodine immediately solution has occurred:

Oxygen consumed = 6.3 and 5.96.

Oxygen required to oxidise dinitrohydrazobenzene to dinitroazobenzene = 5.79 per cent.

Dinitrodiacetylhydrazobenzene, $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{N} \cdot \text{Ac} \cdot \text{N} \cdot \text{Ac} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2$.

One gram of dinitrohydrazobenzene was boiled for two hours with 20 c.c. of acetic anhydride, air being excluded. After evaporating off the excess of acetic anhydride, the mass was extracted with cold chloroform, and the residue crystallised from boiling glacial acetic acid. The product separated in colourless plates, which melted at $188-189^\circ$. It was insoluble in cold alkali hydroxides, but on boiling gave the deep blue colour of dinitrohydrazobenzene. (Found, $N = 15.81$. Calc., $N = 15.64$ per cent.)

4:4'-Nitronitrosohydrazobenzene, $\text{NO} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2$.

This compound constitutes the first stage of the action of alkali hydroxides on dinitrohydrazobenzene. The best conditions for obtaining it in a pure state free from unconverted dinitrohydrazobenzene and from the bisnitrobenzeneazo-azobenzene produced by further condensation were only ascertained after a long series of experiments. Although the condensation commences almost immediately, the rate of the reaction is dependent on the temperature of the solution and its concentration in alkali hydroxide; thus with sodium hydroxide solutions of from 10 to 20 per cent. the reaction is much slower than with solutions of only 3 per cent. With solutions of the former strength and at a temperature of about 15° we obtained colloidal mixtures, in which dinitrohydrazobenzene largely preponderated, but which, nevertheless, exhibited very different properties from the latter in the pure state (see introduction). It was finally ascertained that a complete conversion into

the nitronitroso-compound, without any further condensation, is effected by allowing dinitrohydrazobenzene dissolved in eighty parts of 3 per cent. sodium hydroxide to remain at 25° (laboratory summer temperature) for from six to sixteen hours. The operation is best carried out in a bottle provided with a well-fitting, greased stopper, and nearly filled in order to exclude air. The progress of the reaction can be followed by precipitating at intervals small samples of the filtered solution with acetic acid, and dissolving the precipitate in concentrated sulphuric acid. After only a minute or two the solution in sulphuric acid is pure yellow (unaltered dinitrohydrazobenzene), after ten minutes it is reddish-orange, after half an hour red, and after five hours pure crimson, whilst after sixteen hours no further change is visible. When this point is reached the violet-blue solution is filtered quickly from precipitated dinitroazobenzene, and the filtrate allowed to run directly into an excess of dilute acetic acid. The product was a highly voluminous, gelatinous, reddish-orange precipitate, readily soluble in cold glacial acetic acid, acetone, ether, etc. It was washed thoroughly with water, pressed, dried at the ordinary temperature, and dissolved in acetone. On quickly evaporating the acetone the compound crystallised in small, orange-red cubes with a violet reflex. It is necessary to work quickly in order to avoid condensation of the nitronitroso-compound to bisnitrobenzeneazo-azobenzene. *Nitronitrosohydrazobenzene* is readily soluble in solvents such as acetone, alcohol, ether, acetic acid, but sparingly so in hydrocarbons. The solution in acetone has a deep yellow colour, which was found to be about forty times as intense as a similar solution of dinitrohydrazobenzene. The substance has pronounced tinctorial properties, dyeing silk from an aqueous alcoholic solution in red shades, which are changed to blue by immersion in dilute sodium hydroxide. It has no definite melting point, but begins to decompose at about 203°. Its alkali hydroxide solution has a more violet tint of blue than that of dinitrohydrazobenzene. Like the latter it is decolorised by air or iodine. In addition to its acid properties the compound appears also to be a weak base, giving pink solutions with aqueous acids. It dissolves in concentrated sulphuric acid with a pure crimson colour, which is changed to pure yellow (dinitroazobenzene) on adding a drop of dilute nitric acid.

On account of its instability the compound was analysed in the air-dried condition, the percentage of moisture it contained being determined simultaneously by drying at 140°, and the correction introduced:

1970 GREEN AND BEARDER: THE ALKALINE CONDENSATIONS OF

0.0967 * gave 0.1990 CO₂ and 0.0348 H₂O. C=56.05; H=3.95.
 0.0964 * " 0.1992 CO₂ " 0.0367 H₂O. C=56.34; H=4.22.

 0.0991 * " 19.6 c.c. N₂ at 25° and 757.5 mm. N=22.64.
 0.1006 * " 19.9 c.c. N₂ " 26.5° " 760.3 mm. N=22.73.
 0.0943 * " 18.3 c.c. N₂ " 23° " 754 mm. N=22.73.
 Mean: C=55.83; H=4.09; N=22.7.

C₁₂H₁₀O₃N₄ requires C=55.67; H=3.91; N=21.7 per cent.

Reduction in a boiling acetic acid solution with a standard solution of titanium trichloride gave the following results:

Hydrogen consumed=5.36 and 5.06.

Hydrogen required for reduction to *p*-phenylenediamine=4.70 per cent.

Titration of the alkaline solution with standard iodine in an atmosphere of hydrogen (in the manner described above, but without previously dissolving in acetone) gave the following results:

Oxygen consumed=5.55 and 5.53.

Oxygen required to oxidise nitronitrosohydrazobenzene to nitro-nitrosoazobenzene=6.15 per cent.

Attempts to isolate nitronitrosoazobenzene from the orange-yellow precipitate formed in this reaction proved unsuccessful, the nitroso-compound apparently undergoing further condensation in the alkaline medium or during subsequent purification.

The conclusion based on the above analyses, that under the influence of alkali hydroxides two molecular proportions of dinitrohydrazobenzene give rise to one of nitronitrosohydrazobenzene and one of dinitroazobenzene, was further supported by the following quantitative experiments:

A. 3.75 Dinitrohydrazobenzene gave 1.632 nitronitrosohydrazobenzene and 1.879 dinitroazobenzene. The quantities theoretically required are 1.765 of the former and 1.861 of the latter.

B. A solution of 0.0522 dinitrohydrazobenzene in 3 per cent. sodium hydroxide was allowed to remain for five hours at 25°, air being carefully excluded by means of hydrogen. At the end of this time the solution was titrated with standard iodine (in absence of air) until the disappearance of the blue colour.

The iodine required was equivalent to 0.00132 gram of oxygen.

Percentage of oxygen consumed=2.5, that is, approximately half the quantity (5.79) which would have been required had the solution been titrated immediately.

* Dry.

This substance is readily formed by further condensation of nitronitrosohydrazobenzene, either by heating the alkaline solution or by boiling the substance itself with neutral solvents. In place of employing nitronitrosohydrazobenzene itself, the alkaline solution of dinitrohydrazobenzene may be directly heated, in which case dinitroazobenzene is formed simultaneously.

I. Finely powdered nitronitrosohydrazobenzene was placed in a well-stoppered bottle filled with about fifty parts of aqueous 3 per cent. sodium hydroxide, and heated in boiling water until the blue colour had entirely disappeared, leaving a red liquid, in which was suspended a bright orange precipitate. The time of heating required was about four hours. The orange precipitate was collected, well washed with water, and dried. The crude product was almost pure, and melted at about 285° . It contained no dinitroazobenzene.

II. About $1\frac{1}{2}$ grams of dinitrohydrazobenzene were heated as above with 70 c.c. of aqueous 3 per cent. sodium hydroxide. When the conversion was complete, the precipitate was collected, washed, and dried. It was then boiled with glacial acetic acid, which dissolved about half the whole, and on cooling deposited dinitroazobenzene in the characteristic orange plates, melting at $222.5-223^\circ$. The insoluble residue was dissolved in a large volume of boiling solvent-naphtha, from which after filtration and cooling bisnitrobenzeneazo-azobenzene crystallised in very small, brownish-orange needles, melting at $285-286^\circ$.

III. 0.1748 Gram of nitronitrosohydrazobenzene was boiled with 50 c.c. of solvent naphtha until it dissolved completely (about six hours' boiling were necessary). The solution was concentrated to about half its volume, and allowed to cool, when the condensation product crystallised out in microscopic, orange-brown needles, which melted at $284-285^\circ$. The yield was 0.1042 gram, the conversion being complete.

For analysis the substance was dried at 140° :

0.0923 gave 0.2022 CO_2 and 0.0297 H_2O . $\text{C}=59.74$; $\text{H}=3.57$.

0.0863 „ 16.6 c.c. N_2 at 30.5° and 773 mm. $\text{N}=22.2$.

0.0718 „ 14 c.c. N_2 at 23° and 767 mm. $\text{N}=22.5$.

$\text{C}_{24}\text{H}_{16}\text{O}_4\text{N}_8$ requires $\text{C}=60.0$; $\text{H}=3.33$; $\text{N}=23.3$ per cent.

This constitution is further supported by a determination of the relative quantity of condensation product and dinitroazobenzene produced from a given weight of dinitrohydrazobenzene:

0.9024 dinitrohydrazobenzene gave 0.4531 bisnitrobenzeneazobenzene and 0.4372 dinitroazobenzene. This approximation is very closely to that theoretically required.

Bisnitrobenzeneazo-azobenzene crystallises in very small, orange needles or leaflets, and is very sparingly soluble in all solvents. Its concentrated sulphuric acid solution is cherry-red, which becomes more crimson on addition of a small quantity of water, and is not decolorised by a drop of dilute nitric acid (distinction from the nitronitroso-compound). Alkaline reducing agents convert it into a compound which dissolves in concentrated sulphuric acid with a blue colour, and the investigation of which is at present proceeding.

DEPARTMENT OF TINCITORIAL CHEMISTRY,
UNIVERSITY, LEEDS.

CCXXIII.—*Trimercuridiethylammonium Nitrite*.

By PRAPULLA CHANDRA RÂY and JITENDRA NATH RAKSHIT.

It is well known that when a solution of mercuric chloride is treated with ammonia, the so-called infusible white precipitate is obtained, to which the formula $\text{NHg}^{\text{II}}\text{H}_2\text{Cl}$ has been assigned. One of us has shown that the interaction of mercuric nitrite and aqueous ammonia gives rise to dimercuriammonium nitrite, $\text{NHg}_2^{\text{II}}\text{NO}_2$ (Trans., 1902, 81, 645). This compound may be regarded as ammonium nitrite, in which the four atoms of hydrogen have been displaced by two atoms of dyad mercury. If mercuric chloride is acted on by ethylamine instead of ammonia, the alkyl substituted compound, $\text{NHg}^{\text{II}}\text{EtHCl}$, is, as might be expected, the product of reaction.

We treated a solution of mercuric nitrite with methylamine with a view to ascertain if the formation of a corresponding alkyl derivative takes place. Although we failed to obtain the expected compound, dimercuriammonium nitrite being the product, an examination of the filtrate led to the isolation of methylammonium nitrite (this vol., p. 1016). Reference has already been made to the fact that, by the interaction of ethylamine and mercuric nitrite, not only dimercuriammonium nitrite, but also the alkyl substituted compound, trimercuridiethylammonium nitrite, $\text{N}_3\text{Hg}_3^{\text{II}}\text{Et}_2(\text{NO}_2)_2$, is obtained (this vol., p. 1470). Ethylammonium nitrite, of course, remains in the filtrate.

Method of Preparation.—To a solution of mercuric-sodium nitrite is added an aqueous solution of ethylamine, taking care that the beaker is vigorously shaken after each addition. The reaction may

be taken as completed when the odour of ethylamine distinctly persists, even after a lapse of several minutes. The flocculent, heavy precipitate is washed by the aid of the pump, and dried in a steam-oven. The substance is perfectly white, whereas dimercuriammonium nitrite is pale yellow. In fact, by the physical difference in this property alone the one could be distinguished from the other. By a little practice the conditions which favour the formation of trimercuridiethylammonium nitrite to the exclusion of dimercuriammonium nitrite can be secured. The reaction evidently takes place according to the equations:

The substance dissolves readily in hydrochloric acid with the evolution of nitrous fumes.

Found: $\text{Hg} = 75.30, 75.33$; $\text{C} = 6.24, 6.02$; $\text{N} = 7.30, 7.72$.

$\text{C}_{12}\text{H}_{10}\text{O}_4\text{N}_4\text{Hg}_3\cdot\text{H}_2\text{O}$ requires $\text{Hg} = 75.37$; $\text{C} = 6.03$; $\text{N} = 7.04$ per cent.

The hydrogen was not estimated owing to the risk of vapour of mercury entering into the calcium chloride tube, and thus vitiating the results. The salt evidently contains one molecule of water of crystallisation; this is quite in accord with the fact that dimercuriammonium nitrite, which is derived from a single molecule of ammonium nitrite, contains half a molecule of water.

The filtrate was subjected to distillation, and the presence of ethyl alcohol in the distillate was proved by the iodoform test; it was no doubt derived from the decomposition of the ethylammonium nitrite.

It is of interest to note that whilst by the action of ammonia and alkylated ammonia on mercuric chloride the compounds $\text{NHg}^{II}\text{H}_2\text{Cl}$ and $\text{NHg}^{II}\text{EtHCl}$ respectively are formed, with mercuric nitrite there are always obtained products in which all the atoms of hydrogen of ammonium nitrite are displaced by mercury and alkyl radicles.*

We are engaged in studying the action of other alkylated ammonias on mercuric nitrite.

CHEMICAL LABORATORY,
PRESIDENCY COLLEGE, CALCUTTA.

* In this communication we have used the term dimercuriammonium nitrite in preference to dimercurammonium nitrite, as the former appears to be in strict conformity with scientific nomenclature.

CCXXIV.--*Studies of Ammonium Solutions. Part I.*
*An Ammonium Electrode.**

By ROLAND ERGAR SLADE.

It has been shown (Le Blanc, *Zeitsch. physikal. Chem.*, 1890, 5, 467; Coehn, *Zeitsch. anorg. Chem.*, 1900, 25, 430; Smith, *J. Amer. Chem. Soc.*, 1907, 29, 844; see also McCoy and Moore, *ibid.*, 1911, 33, 273) that ammonium, NH_4 , behaves like a metal in that it is able to form an amalgam with mercury, and that NH_4 in this amalgam is able partly to displace sodium, potassium, and barium from aqueous solutions of their salts. From analogy it seemed probable that when ammonia and hydrogen were dissolved in platinum there would be some ammonium formed, and that there would be an equilibrium:

between ammonia, atomic hydrogen, and ammonium. It is known that hydrogen dissolved in platinum exists in the atomic state (Richardson, Nocol, and Parnell, *Phil. Mag.*, 1904, [vi], 8, 1). If this equilibrium exists, a piece of platinised platinum saturated with hydrogen and ammonia would act as an ammonium electrode in a solution containing ammonium ions.

By Nernst's theory the potential, e , of this electrode would be:

$$e = -\frac{RT}{F} \ln \frac{k_1 C}{c} \quad \dots \dots \dots (1)$$

where: k is a constant.

C is the concentration of ammonium in the platinum.

c is the concentration of ammonium in the aqueous solution.

This potential will be that of the reaction:

and will vary with the partial pressures of NH_3 and H_2 , and with the concentration of the ammonium ions in the aqueous solution. We will denote concentrations in the platinum by $[\]'$, and in the aqueous solution by $[\]$, for instance, $[\text{NH}_3]'$ is the concentration of ammonia in the platinum, and $[\text{NH}_3]$ the concentration of ammonia in the aqueous solution.

If we have the equilibrium $\text{NH}_3 + \text{H} \rightleftharpoons \text{NH}_4$ in the platinum:

$$[\text{NH}_4]' = k_2 [\text{H}]' \cdot [\text{NH}_3]' \quad \dots \dots \dots (2)$$

* During the course of this investigation, Brönsted (*Zeitsch. physikal. Chem.*, 1911, 77, 129) has published a paper on the free energy of formation of double salts in which he describes the use of a hydrogen electrode in ammonium chloride solutions under a definite partial pressure of ammonia.

The concentration of ammonia, NH_3 , in the platinum will be proportional to the partial pressure of ammonia. Or:

$$[\text{NH}_3]' = k_{\text{PNH}_3} \quad . \quad . \quad . \quad (3).$$

Therefore from (2) and (3):

$$[\text{NH}_4]' = k_2 k_3 [\text{H}] \cdot p_{\text{NH}_3} \quad . \quad . \quad . \quad (4).$$

Now:

$$[\text{H}]' = k_4 \sqrt{[\text{H}_2]}'$$

and

$$[\text{H}_2]' = k_5 p_{\text{H}_2}$$

where p_{H_2} is the partial pressure of hydrogen over the platinum and solution.

Therefore:

$$[\text{H}]' = k_4 k_5^{1/2} p_{\text{H}_2}^{1/2}$$

and from (4):

$$[\text{NH}_4]' = k_2 k_3 k_4 k_5^{1/2} p_{\text{NH}_3} p_{\text{H}_2}^{1/2}$$

Therefore (1) becomes:

$$e = -\frac{RT}{F} \ln \frac{k_1 k_2 k_3 k_4 k_5^{1/2} p_{\text{NH}_3} p_{\text{H}_2}}{[\text{NH}_4]'}$$

or at 25° collecting the constants:

$$e = -0.059 \log \frac{k_{\text{PNH}_3} p_{\text{H}_2}}{[\text{NH}_4]'} \quad . \quad . \quad . \quad (5).$$

Even if this electrode reaction $\text{NH}_4 \rightarrow \text{NH}_4^+ + \ominus$ does not actually take place, the potential of the electrode will still be that of the reaction:

For if it is simply a hydrogen electrode, we have:

$$e = -0.059 \log \frac{k_6 p_{\text{H}_2}}{[\text{H}]'} \quad . \quad . \quad . \quad (6).$$

But:

$$[\text{H}'] = \frac{K_w}{[\text{OH}']}$$

and

$$[\text{OH}'] \cdot [\text{NH}_4]' = k_7 [\text{NH}_4\text{OH}] = k_8 [\text{NH}_3] = k_9 p_{\text{NH}_3}$$

therefore:

$$[\text{OH}'] = \frac{k_9 p_{\text{NH}_3}}{[\text{NH}_4]'}$$

and

$$[\text{H}'] = \frac{K_w \cdot [\text{NH}_4]'}{k_9 p} \quad . \quad . \quad . \quad (7).$$

From (6) and (7):

$$e = -0.059 \log \frac{k_6 K_w p_{\text{NH}_3} p_{\text{H}_2}}{k_9 [\text{NH}_4]'}$$

or collecting the constants:

$$e = -0.059 \log \frac{k p_{\text{NH}_3} p_{\text{H}_2}}{[\text{NH}_4^+]},$$

which is identical with (6). Therefore, whether the reaction is:

the potential measured is that of the chemical reaction:

EXPERIMENTAL.

The solution for the cell was made up by weighing out a certain amount of ammonium chloride dissolving in a solution of ammonia of known strength, and making up to 100 c.c. with this solution. The partial pressure of ammonia over such a solution would be approximately that of the partial pressure of the original ammonia solution. By passing a stream of electrolytic gas through the pure ammonia solution and then through the ammonium chloride solution for some hours, the partial pressure over the latter solution was brought to be the same as that over the former. The arrangement was as follows: A gentle stream of electrolytic gas, prepared by the electrolysis of sodium hydroxide solution, was passed through (1) a wash-bottle of the type used by Gauss (*Zeitsch. anorg. Chem.*, 1900, **25**, 236) containing about 200 c.c. of a solution of ammonia of known concentration; (2) a similar wash-bottle containing the same solution; (3) a wash-bottle (ordinary type) containing ammonium chloride solution of the concentration under investigation; (4) the electrode vessel. After sixteen hours the ammonia solution in the first two wash-bottles was renewed, and a stream of hydrogen substituted for the electrolytic gas. The ammonium electrode was connected with a normal calomel electrode, and measurements of the *E.M.F.* made at intervals for several hours. The *E.M.F.* became constant in forty to fifty minutes, and remained quite steady to 0.3 m.v. The hydrogen was prepared by the action of pure dilute sulphuric acid on pure zinc; it was passed through alkaline permanganate solution, and then over red-hot copper gauze. The electrode vessels were of borosilicate glass.* The electrodes were platinised platinum. The electrode vessel and ammonia solutions were kept in a thermostat at 25°.

The potentials were measured by the compensation method, using a calibrated metre bridge and a galvanometer as null instrument. By means of a resistance in series with the bridge, the standard cell was balanced against about 90 cm. of the wire. The standard cadmium cell, which had been tested at the National Physical

* These vessels were made by Mr. Baumbach, of Manchester.

SLADE: STUDIES OF AMMONIUM SOLUTIONS. PART I. 1977

Laboratory, was taken as 1.0183 volts at 20°. The accuracy of measurement when the resistance of the cell was low was 0.1 m.v. Three normal calomel electrodes were made up as described in Ostwald-Luther's "Physico-Chemische Messungen" (1900). Three decinormal calomel electrodes were also made up. The normal calomel electrodes were tested from time to time against the decinormal electrodes, and were always found to give 0.0534 ± 0.0002 v.

The following cells were measured:

TABLE I.

Hg	HgCl ₂ .N-KCl	N-KCl	0.06 <i>N</i> -NH ₄ Cl	H ₂ NH ₃ (0.01 <i>N</i>)	0.783 "

NH₃(2*N*) denotes that the partial pressure of ammonia over the solution was equal to that over a twice normal aqueous ammonia solution. The cells with 0.08*N*-NH₄Cl had so great a resistance that the measurements were only correct to ± 0.1 m.v.

The single potentials of the ammonium electrodes can be calculated from the above values by subtracting 0.283, which is the value of the single potential of the normal calomel electrode at 25°, taking the normal hydrogen electrode as zero. These values are given in table II under *e*.

From equation (5):

$$e = -0.059 \log \frac{K p_{\text{NH}_3} p_{\text{H}_2}^{\frac{1}{2}}}{[\text{NH}_4^+]}$$

Therefore:

$$e = e_0 - 0.059 \log \frac{p_{\text{NH}_3} p_{\text{H}_2}^{\frac{1}{2}}}{[\text{NH}_4^+]}$$

where *e*₀ is the normal potential of ammonium. It is the potential which a platinised platinum electrode would give in a solution normal in respect to ammonium ions, the partial pressures of ammonia and hydrogen over the solution being each one atmo-

1978 SLADE: STUDIES OF AMMONIUM SOLUTIONS. PART I.

sphere. In table II under e_0 are the values of this quantity calculated in each case by the equation:

$$e_0 = e + 0.059 \log \frac{p_{\text{NH}_3} p_{\text{H}_2}}{[\text{NH}_4^+]}$$

Under $f(c)$ are given the values of

$$0.059 \log \frac{p_{\text{NH}_3} p_{\text{H}_2}}{[\text{NH}_4^+]}$$

The *E.M.F.* of the liquid potentials has been neglected, as it is in all the cases considered not greater than one millivolt; the migration ratios of ammonium chloride and potassium chlorido are both very nearly 0.5.

Under $[\text{NH}_4^+]$, p_{H_2} , and p_{NH_3} are given the values of these quantities used in calculating $f(c)$ and e_0 . The values of $[\text{NH}_4^+]$ were taken as the sum of the concentrations of the ions derived from the ammonium chloride and from the ammonia, as though each were independent of the other. It would perhaps be more correct in the strong ammonium chloride solutions to assume that the ammonia was quite inappreciably dissociated, since the high concentration of ammonium ions would throw back the dissociation. If we do this, however, it causes a difference of only 0.1 m.v. in the calculated values of $f(c)$. For the degree of dissociation of ammonium chloride at 0.4 and 0.08*N*, the results of Jones and West (*Amer. Chem. J.*, 1905, **34**, 557) were taken, and the value for *N*-ammonium chlorido was obtained by extrapolating from their results. For the ionisation of ammonia, the values of Noyes, Kato, and Sosman (*J. Amer. Chem. Soc.*, 1910, **32**, 159) at 18° up to 0.5*N* were taken. The values for *N* and 2*N* were extrapolated from their values. The values of p_{NH_3} up to *N*- NH_3 were taken from Locke and Forsall

Amer. Chem. J., 1904, **31**, 268), and the value for $2N$ by extrapolating by the formula $p_{\text{NH}_3} = 13.34N + 0.18N^2$, where N is the normality of ammonia in the solution. In calculating the partial pressure of hydrogen, the vapour pressure of water and of the solutions at 25° was taken as 23 mm. The error introduced by this assumption is less than 0.1 m.v. in the case of N -ammonium chloride. These values were not corrected for changes of barometric pressure, or for the pressure in the electrode vessel being slightly greater than that of the atmosphere. Such differences make no appreciable difference in the value of $f(c)$.

Taking the mean of our values of e_0 , we have for the potential of the ammonium electrode at 25° :

$$e = -0.486 - 0.059 \log \frac{p_{\text{NH}_3} p_{\text{H}_2}^{\frac{1}{2}}}{[\text{NH}_4^+]}$$

The agreement of the values of e_0 over wide ranges of concentration is better than for any other hydrogen electrode; for instance, compare the results collected by Wilmore (*Zeitsch. physikal. Chem.*, 1900, **35**, 302). Moreover, the solutions here investigated were weakly alkaline, whilst Allmand (this vol., p. 842) found that the hydrogen electrode was particularly untrustworthy in dilute alkaline (sodium and potassium hydroxide) solutions. This steadiness of the electrode suggests the probability that the electrode reaction is chiefly $\text{NH}_4^+ \rightarrow \text{NH}_3 + \text{H}^+$, and not $\text{H}^+ \rightarrow \text{H}_2$.

Formation of Complexes.—In the above calculations the formula of the ammonium ion has been supposed to be NH_4^+ , but in the presence of excess of free ammonia it is quite feasible to suppose that NH_3 might be added on, and we should get some complexes of the type $(\text{NH}_3)_x\text{H}^+$. v. Braun (Ahegg's, "Handbuch," **3**, 74) states that it is not improbable that they exist at high concentrations. By the following method we can determine the average value of x in the solution. If there are no complexes, that is, if the only ions are NH_4^+ or NH_3H^+ , we shall find $x=1$.

In the aqueous solution there must exist the equilibrium:

and therefore:

$$K[\text{H}^+] = \frac{[(\text{NH}_3)_x\text{H}^+]}{[\text{NH}_3]^x}.$$

In two solutions of different concentrations the ratio of the hydrogen ion concentrations:

$$\frac{[\text{H}^+]_1}{[\text{H}^+]_2} = \frac{[(\text{NH}_3)_x\text{H}^+]_1 [\text{NH}_3]_2^x}{[(\text{NH}_3)_x\text{H}^+]_2 [\text{NH}_3]_1^x}.$$

Taking logarithms:

$$\log \frac{[H^+]_1}{[H^+]_2} = \log \frac{[(NH_3)_x H^+]_1}{[(NH_3)_x H^+]_2} - x \log \frac{[NH_3]_1}{[NH_3]_2} \quad (8).$$

If, however, the two solutions have the same concentration of ammonium chloride, we have:

$$[(NH_3)_x H^+]_1 = [(NH_3)_x H^+]_2,$$

and from (8):

$$\log \frac{[H^+]_1}{[H^+]_2} = -x \log \frac{p_1}{p_2},$$

where p is the partial pressure of ammonia.

Therefore:

$$x = \frac{\log \frac{[H^+]_1}{[H^+]_2}}{\log \frac{p_2}{p_1}}$$

If we measure of *E.M.F.* of a cell of the type:

we can calculate the value of $\log \frac{[H^+]_1}{[H^+]_2}$, for the cell consists of two

hydrogen electrodes each with hydrogen at the same pressure, but surrounded by solutions of different hydrogen ion concentration; thus:

$$\log \frac{[H^+]_1}{[H^+]_2} = + \frac{e}{0.059}.$$

The values of p_1 and p_2 may be determined as above; x may then be calculated.

In table III are given the values of e observed, and the values of x calculated from them. The value of e was not directly measured; each half of the cell was measured against a normal calomel electrode. The observations are given in table I.

TABLE III.

Cell.				e .	x .		
$NH_3(2N)$	H_2	$N-NH_4Cl$	H_2	$NH_3(N)$	-0.020	1.18
$NH_3(2N)$	H_2	$0.4 N-NH_4Cl$	H_2	$NH_3(N)$	-0.022	1.21
$NH_3(N)$	H_2	$N-NH_4Cl$	H_2	$NH_3(0.5N)$	-0.020	1.09
$NH_3(N)$	H_2	$0.4 N-NH_4Cl$	H_2	$NH_3(0.5N)$	-0.020	1.09
$NH_3(0.5N)$	H_2	$N-NH_4Cl$	H_2	$NH_3(0.05N)$	-0.058	0.99
$NH_3(0.5N)$	H_2	$0.4 N-NH_4Cl$	H_2	$NH_3(0.05N)$	-0.058	0.99
$NH_3(0.05N)$	H_2	$N-NH_4Cl$	H_2	$NH_3(0.01N)$	-0.042	1.03
$NH_3(0.05N)$	H_2	$0.4 N-NH_4Cl$	H_2	$NH_3(0.01N)$	-0.041	1.00
$NH_3(0.05N)$	H_2	$0.03N-NH_4Cl$	H_2	$NH_3(0.01N)$	-0.040	0.97

The values of x are almost exactly unity in the more dilute solutions, although there seems to be a slight tendency to form complexes in the more concentrated solutions. It will be noticed that in the above calculation the pressure of hydrogen has been

SLADE: STUDIES OF AMMONIUM SOLUTIONS. PART I. 1981

assumed to be the same over both electrodes in any one cell. The errors introduced by this assumption are of the order of 1 per cent. in the first and second cells, and quite negligible in the other cells.

In solutions containing no ammonium chloride, that is, in solutions of ammonia in pure water, we have $[\text{OH}'] = [(\text{NH}_3)_x\text{H}']$, since the concentration of H' is negligible compared with the concentration of ammonium ions. Therefore equation (8) becomes:

$$\log \frac{[\text{H}']_1}{[\text{H}']_2} = \log \frac{[\text{OH}']_1}{[\text{OH}']_2} - x \log \frac{p_1}{p_2}.$$

But $[\text{OH}'] = \frac{K_w}{[\text{H}']}$, where K_w is a constant.

Therefore:

$$2 \log \frac{[\text{OH}']_2}{[\text{OH}']_1} = -x \log \frac{p_1}{p_2},$$

and

$$x = 2 \frac{\log \frac{[\text{OH}']_1}{[\text{OH}']_2}}{\log \frac{p_1}{p_2}}.$$

We can calculate some values of x in pure ammonia solutions by this formula from the results of Noyes, Kato, and Sosman on the ionisation of ammonia solutions, and a knowledge of the pressure of ammonia over the solutions. The data are only available up to 0.5*N*-ammonia. The values obtained are all approximately unity.

Summary.

The potential of the ammonium electrode at 25° has been determined, and has been shown to depend upon the partial pressures of hydrogen and ammonia, and on the concentration of ammonium ions in the following way:

$$e = -0.486 - 0.059 \log \frac{p_{\text{NH}_3} p_{\text{H}_2}^{\frac{1}{2}}}{[\text{NH}_4']},$$

where $e = e_{\text{electrode}} - e_{\text{solution}}$, and the potential of the hydrogen electrode in a solution of normal hydrogen ion concentration is taken as zero.

It has been shown that complexes of the form $(\text{NH}_3)_x\text{H}'$, where x is greater than one, do not exist to any appreciable extent in dilute aqueous ammonia or ammoniacal ammonium chloride solutions, although there is some evidence of their existence at higher concentrations.

Part of the expenses of this research were borne by a grant from the Chemical Society.

The author wishes to thank Professor F. G. Donnan for his kind interest in this work, and Mr. R. Kingan for some assistance in the experimental work.

THE MUSEUMS LABORATORY OF PHYSICAL AND ELECTRO-CHEMISTRY,
UNIVERSITY OF LIVERPOOL.

CCXXV.—*Studies in the Camphane Series. Part XXX. Constitution of Pernitrosocamphor (Camphenylnitroamine).*

By MARTIN ONSLOW FORSTER, JOHN ROBERT TROTTER, and
JACOB WEINTROUBE.

PERNITROSOCAMPHOR or camphenylnitroamine, discovered by Angeli and Rimini (*Ber.*, 1895, **28**, 1077), and independently by Tiemann (*loc. cit.*, 1879), is produced in association with camphorimine nitrite by the action of nitrous acid on camphoroxime, which also yields the pernitroso-derivative under the influence of dilute nitric acid or of nitrogen peroxide (*Trans.*, 1897, **71**, 197). It has been the subject of numerous inquiries, notably by Hantzsch and Dollfus (*Ber.*, 1902, **35**, 260), Scholl (*Annalen*, 1905, **338**, 1; 1906, **345**, 363), Angelucci (*Annalen*, 1905, **341**, 172), Angeli and Castellana (*Atti R. Accad. Lincei*, 1905, [v], **14**, 669), who directed their efforts principally towards elucidating the problem of atomic arrangement in the N_2O_2 group. Without following the ramifications of this discussion, it may be stated that at present the rival formulae are:

Hantzsch; Scholl.

Angelucci.

Angeli and Castellana.

The expression originally used by Tiemann, $C_8H_{14} \begin{array}{c} \diagup CH \\ | \\ C \cdot NH \cdot NO_2 \end{array}$ in conformity with which he called the substance camphenylnitroamine, no longer meets with favour, although its tautomeric form, $C_8H_{14} \begin{array}{c} \diagup CH \\ | \\ C \cdot N \cdot NO \cdot OH \end{array}$ is the one used by Hantzsch (*loc. cit.*) in representing the potassium derivative.

In spite of the labour which has been already expended on the problem, it cannot be said that the position is a satisfactory one, and it is difficult to see how a definite conclusion is to be drawn between the nitroimine (Hantzsch and Scholl) and pernitroso-formula (Angeli and Castellana). It is not claimed that the present communication offers a final settlement, but we believe that the fresh material brought forward serves to emphasise an aspect of the question which has hitherto escaped the attention it deserves.

Very soon after the discovery of the substance it was found that the potassium derivative may be readily oxidised to camphoric acid (Mahla and Tiemann, *Ber.*, 1896, 29, 2811), a fact which confirmed Tiemann in his representation; we find that if potassium ferricyanide is used, camphorquinone is the principal product, which somewhat discounts the presence of an ethenoid linking. Both experiments, however, seem to indicate that in the potassium derivative there exists an association between the pernitroso-group and the second carbon atom (the α -position in camphor) closer than has been hitherto suspected. A more convincing indication of this is to be found in the behaviour of potassium pernitrosocamphor towards diazonium salts. We find that on mixing neutral or slightly alkaline cold aqueous solutions of these materials, there takes place a coupling process, in which the arylazo-group attaches itself to the second carbon atom, leaving the pernitroso-group intact, the products having the properties of camphorquinonearyldiazones, in which the oxygen is replaced by the pernitroso-group; by the action of hydroxylamine and of semicarbazide on these pernitrosocamphorquinonearyldiazones, oximes and semicarbazones of the respective camphorquinonearyldiazones are formed, and in this way there has been obtained, for example, the oxime of camphorquinonephenylhydrazone, previously prepared by the action of hydroxylamine on camphorquinonephenylhydrazone itself (*Trans.*, 1909, 95, 955):

Furthermore, by the action of nitrosyl chloride on potassium pernitrosocamphor, there arises the pernitroso-derivative of pernitrosocamphor, which likewise exchanges the pernitroso-nucleus for the oximino-group under the influence of hydroxylamine, leading to the β -dioxime of camphorquinone:

Thus it appears that the replacement of oxygen in camphor by the pernitroso-group confers on the α -position properties recalling

those of the CH_2 group in ethyl malonate, barbituric acid, nitroethane, and kindred substances, with, however, this difference, that pernitrosocamphor does not undergo condensation with benzaldehyde or with *p*-nitrosodimethylaniline.

Although it is not necessary to suppose that in pernitrosocamphor itself there is any direct association between the α -position and the pernitroso-group, it is difficult to believe that the potassium derivative could take part in such changes unless this connexion has been established, and we therefore suggest that the existing knowledge of these substances may be brought into harmony with the formulæ:

The above representation of pernitrosocamphor is in agreement with the direct production of the substance from camphoroxime and nitrosyl chloride (Angelucci), and is free from the objection which attaches to regarding the substance as a nitrite of camphoroxime. This latter view is discounted by the following circumstance. If pernitrosocamphor were the nitrite of camphoroxime, alcoholic alkali hydroxide should hydrolyse it to the original oxime, whereas we find that under conditions which leave camphoroxime unchanged, camphor itself is the only product. On the other hand, Angelucci's experiment may be used as an argument in support of the new formula, which might arise from the nitrite of camphoroxime by the mutual satisfaction of the partial valency existing in the two unsaturated linkings which that substance would present:

Moreover, the attachment simultaneously to nitrogen and oxygen, which characterises the carbon atom bearing the pernitroso-group, would in some measure explain the facility with which that group is removed by alkalis, amines, hydroxylamine, and semicarbazide, at the same time accounting for the production of camphoroxime, camphanazine, and the isomeric bornylamines by reducing agents, as observed by Angeli and Castellana.

Whilst it has to be admitted that the suggested formulæ for pernitrosocamphor and its potassium derivative are purely speculative, the same remark applies to those which have been put forward by other workers. They seem to us, however, to offer fewer steric

obstacles to the explanation of the facts. For instance, passage from the labile to the stable form of pernitrosocamphor would be comparatively smooth:

the explanation given by Hantzsch and by Scholl involving a more profound intramolecular disturbance. Moreover, production of the pernitrosocamphorquinonearyllhydrazones from the potassium derivative and diazonium salts would harmonise with the mechanism of coupling brought to light by Dimroth and Hartmann (*Ber.*, 1908, **41**, 4012), who showed that when benzenediazonium chloride couples with enolic tribenzoylmethane, a benzene-*O*-azo-compound is formed first, and changes into the isomeric benzene-*C*-azo-compound on fusion. The transference of the benzeneazo-nucleus from oxygen over nitrogen to carbon in enolic pernitrosocamphor is a process more readily conceivable than the alternative explanations, which involve a more circuitous route.

EXPERIMENTAL.

Pernitrosocamphorquinonephenylhydrazone,

A solution of benzenediazonium chloride prepared from 4 grams of aniline was treated at zero with a 20 per cent. solution of sodium carbonate until neutral or faintly alkaline, and then poured into a cold solution of the potassium derivative of pernitrosocamphor (10 grams) in water. The product was a sticky, yellow mass, which was washed by decantation with ice-cold water, and afterwards rubbed with a very small quantity of alcohol, the resulting crystals being drained on porous earthenware; having been treated in this way three or four times, the product was dissolved in cold acetone, from which water precipitated golden-brown crystals. After recrystallisation from warm benzene the compound melted at 104°:

0.1729 gave 28.8 c.c. N_2 at 21° and 745 mm. $\text{N} = 18.65$.

$\text{C}_{16}\text{H}_{20}\text{O}_2\text{N}_4$ requires $\text{N} = 18.66$ per cent.

It is noteworthy that on combustion the substance liberates oxygen, which is apt to escape the copper spiral, and indicate a high percentage of nitrogen; the above result, for example, is reduced from over 21 per cent. by absorption with potassium pyrogallate. The substance dissolves readily in organic media, excepting petroleum; a solution containing 0.0997 gram, made up

to 20 c.c. with chloroform, gave α_D 1°52' in a 1-dm. tube, whence $[\alpha]_D$ 374°40'. Distinctive colour reactions are given with nitric and sulphuric acids, the latter producing a colour which is intense purple by reflected, deep blue by transmitted light; dilution with water changes this to bright yellow, becoming claret-colour with potassium hydroxide. A solution in concentrated nitric acid is claret-colour by reflected, green by transmitted light, green flocks separating on dilution with water.

Action of Hydroxylamine.—A solution of the pernitroso-derivative in dry pyridine containing excess of free hydroxylamine was allowed to remain during four weeks at 40°, when precipitation with water gave yellow needles, melting at 195°, identical with the oxime of camphorquinonephenylhydrazone already described (*loc. cit.*). The same compound was formed on heating an alcoholic solution of the pernitroso-derivative with aqueous hydroxylamine acetate during two to three hours.

Semicarbazone of Camphorquinonephenylhydrazone,

The pernitroso-derivative was dissolved in alcohol, and heated with aqueous semicarbazide acetate under reflux during twenty hours; the filtered liquid gave a crystalline residue on evaporation, this being washed with water, and recrystallised from alcohol, which deposited lustrous, golden-yellow, six-sided plates, melting at 268°:

0.1176 gave 24.1 c.c. N_2 at 18° and 746 mm. $\text{N} = 23.17$.

$\text{C}_{17}\text{H}_{23}\text{ON}_5$ requires $\text{N} = 22.36$ per cent.

The semicarbazone dissolves freely in cold acetone, but less readily in hot alcohol; it is sparingly soluble in boiling benzene, and insoluble in hot petroleum. Concentrated nitric acid develops a green coloration.

Pernitrosocamphorquinone-p-nitrophenylhydrazone,

On attempting to couple the pernitroso-compound with diazotised *p*-nitroaniline, the product was very sticky, as before, but could not be crystallised. By adding the solution of potassium pernitrosocamphor (10 grams) to the neutralised solution of *p*-nitrobenzene-diazonium chloride (prepared from 5.9 grams of *p*-nitroaniline instead of vice versa, however, the derivative was precipitated in separate particles; after treatment with a small quantity of cold

methyl alcohol, the drained substance was recrystallised from benzene, being deposited in yellow prisms, melting at 96° :

0.1146 gave 18.4 c.c. N_2 at 19° and 747 mm. $N=18.15$.

$C_{16}H_{19}O_4N_5$ requires $N=20.29$ per cent.

The deficit in nitrogen was shown to be due to solvent of crystallisation, for the substance, after being heated or kept in a desiccator, melted at 178° :

0.9040 lost 0.0959 during five hours at 70° . Loss = 10.61.

0.1470 (residue) gave 26.4 c.c. N_2 at 17° and 764 mm. $N=20.86$.

$C_{16}H_{19}O_4N_6 + \frac{1}{2}C_6H_6$ requires loss = 10.16; $N=18.22$ per cent.

$C_{16}H_{19}O_4N_5$ requires $N=20.29$ per cent.

The substance is readily soluble in acetone and in hot benzene, but is insoluble in petroleum.

Oxime of Camphorquinone-p-nitrophenylhydrazone,

On heating an alcoholic solution of pernitrosocamphorquinone-p-nitrophenylhydrazone with aqueous hydroxylamine acetate during some hours, the liquid deposited on evaporation a residue which hardened when treated several times with water; recrystallisation from alcohol gave brown needles, melting at 186° :

0.2057 gave 32.3 c.c. N_2 at 18.5° and 755 mm. $N=18.02$.

$C_{16}H_{20}O_3N_4$ requires $N=17.72$ per cent.

The substance forms a cherry-red solution in concentrated sulphuric acid, whilst alcoholic ammonia develops a brilliant carmine. It dissolves readily in hot alcohol and in cold chloroform or ethyl acetate, but is more sparingly soluble in boiling benzene, and is insoluble in hot petroleum.

Semicarbazone of Camphorquinone-p-nitrophenylhydrazone,

This substance was produced on replacing hydroxylamine in the foregoing reaction by semicarbazide; it crystallised from alcohol in golden-yellow plates, melting and decomposing at 250° :

0.1154 gave 23.6 c.c. N_2 at 20° and 755 mm. $N=23.24$.

$C_{17}H_{22}O_3N_6$ requires $N=23.45$ per cent.

The semicarbazone is freely soluble in cold acetone, but dissolves less readily in chloroform, and only sparingly in boiling benzene; it is insoluble in petroleum. Concentrated sulphuric acid develops an intense, cherry-red coloration, alcoholic ammonia giving a more brownish-red.

Pernitrosocamphorquinone-p-bromophenylhydrazone,

This derivative was obtained in two modifications, which differ distinctly from one another in fusibility and specific rotatory power. The product separated in the form of a bright yellow, granular precipitate on adding aqueous potassium pernitrosocamphor to diazotised *p*-bromoaniline rendered alkaline with sodium carbonate; it altered on the filter to a hard, brown cake, which was treated with cold acetone. The undissolved portion was crystallised from benzene by adding petroleum, which precipitated golden-yellow, transparent prisms, melting at 143° with vigorous intumescence:

0.1563 gave 20.5 c.c. N_2 at 17° and 746 mm. $\text{N}=14.91$.

0.2780 „ 0.1378 AgBr. $\text{Br}=21.09$.

$\text{C}_{16}\text{H}_{19}\text{O}_2\text{N}_4\text{Br}$ requires $\text{N}=14.77$; $\text{Br}=21.11$ per cent.

A solution containing 0.2941 gram, made up to 25 c.c. with chloroform, gave $\alpha_D^{20} 7.05'$ in a 2-dcm. tube, whence $[\alpha]_D^{20} 301.0^\circ$, this value remaining unaltered during ten days. The substance develops an intense, chocolate-brown coloration with concentrated sulphuric acid, changing to weak claret colour, with faint green dichroism, on adding nitric acid.

The acetone filtrate from the foregoing substance deposited a dark brown oil on evaporation, this becoming solid when stirred with dilute hydrochloric acid; recrystallisation from benzene to which petroleum was added gave clear-cut, yellow, transparent prisms, melting at 159° :

0.1823 gave 21.4 c.c. N_2 at 19° and 737 mm. $\text{N}=14.91$.

0.3326 „ 0.1642 AgBr. $\text{Br}=21.01$.

$\text{C}_{16}\text{H}_{19}\text{O}_2\text{N}_4\text{Br}$ requires $\text{N}=14.77$; $\text{Br}=21.11$ per cent.

A solution containing 0.2335 gram, made up to 25 c.c. with chloroform, gave $\alpha_D^{20} 5.050'$ in a 2-dcm. tube when examined immediately; in the course of ten days this had fallen to $4.024'$, when the liquid was almost too dark to transmit the necessary light. The initial and final readings correspond with $[\alpha]_D^{20} 312.3^\circ$ and 235.5° respectively. In recrystallising the substance from a mixture of benzene and petroleum, it was noticed that nodules separated first, followed by silky, yellow needles; no other difference could be detected between these two forms, and on one occasion when a mixture of nodules and needles had separated, the former changed into the latter during one night in the mother liquor.

The dichroism of the bromo-derivative of higher melting point in sulphuric-nitric acid is distinct from that of the more fusible

one, the secondary colour being bright blue. The principal difference between the two substances, however, lies in the behaviour towards petroleum (b. p. 60–80°); this does not dissolve the derivative of higher melting point, whilst 1 gram of the isomeride requires less than 100 c.c. of the boiling solvent for dissolution, separating in lustrous, six-sided plates.

Oxime of Camphorquinone-p-bromophenylhydrazone,

This substance, prepared from the higher melting bromophenylhydrazone and hydroxylamine acetate in aqueous alcohol, crystallised from alcohol in rectangular, primrose prisms, melting at 180°:

0.1989 gave 21.8 c.c. N_2 at 19° and 738 mm. $\text{N}=12.25$.

$\text{C}_{16}\text{H}_{20}\text{ON}_3\text{Br}$ requires $\text{N}=12.00$ per cent.

A solution containing 0.1950 gram, made up to 20 c.c. with chloroform, gave α_D 4°13' in the 2-dcm. tube, whence $[\alpha]_D$ 215.5°. An intense, red coloration is developed by concentrated sulphuric acid, and is bleached on adding nitric acid. The oxime is very sparingly soluble in boiling petroleum, but dissolves freely in cold acetone, chloroform, methyl alcohol, ethyl acetate, or boiling benzene.

Semicarbazone of Camphorquinone-p-bromophenylhydrazone,

This was also prepared from the less fusible bromophenylhydrazone, and crystallised from alcohol in brown, six-sided plates, melting at 265°:

0.1481 gave 22.7 c.c. N_2 at 18° and 760 mm. $\text{N}=17.70$.

$\text{C}_{17}\text{H}_{22}\text{ON}_5\text{Br}$ requires $\text{N}=17.85$ per cent.

The substance is insoluble in petroleum, and dissolves only sparingly in boiling benzene; it is moderately soluble in hot methyl alcohol.

Pernitrosocamphorquinoneoxime (Pernitrosoisonitrosocamphor),

Preliminary experiments showed that there is not any action between potassium pernitrosocamphor and amyl nitrite, even in presence of sodium ethoxide, but nitrosyl chloride, although regenerating a considerable proportion of pernitrosocamphor, leads also to the isonitroso-compound.

Ten grams of the potassium derivative suspended in dry ether were subjected to the action of nitrosyl chloride gas until the liquid became yellow, when it was shaken with dilute sodium hydroxide, and left about 5 grams of pernitrosocamphor on evaporation; the alkaline solution was bright yellow, and gave a bulky, colourless, precipitate with hydrochloric acid, amounting, in various experiments, to between 1 and 3 grams. Recrystallisation from dilute alcohol gave colourless needles, petroleum depositing indefinite, fern-like crystals, resembling those of isonitrosocamphor, and melting at 147.5° :

0.1418 gave 23.5 c.c. N_2 at 17° and 750 mm. $N=18.96$.

$C_{10}H_{11}O_3N_3$ requires $N=18.66$ per cent.

A solution containing 0.1415 gram, made up to 25 c.c. with chloroform, gave $\alpha_D^{20} 1^{\circ}10'$ in the 2-dm. tube, whence $[\alpha]_D^{20} 103.1^{\circ}$. The substance is freely soluble in organic media, excepting petroleum, 250 c.c. of which (b. p. $80-100^{\circ}$) were required by 1.5 gram; it dissolves immediately in sodium hydroxide, developing a yellow coloration, and on adding freshly prepared ferrous sulphate solution to the diluted liquid there is a greenish-blue precipitate, rapidly becoming dark brown, quite distinct from the purple substance produced by isonitrosocamphor in similar circumstances. On allowing an alcoholic solution to remain at 40° with excess of hydroxylamine acetate in water, camphorquinone- β -dioxime began to crystallise within two hours.

The benzoyl derivative, $C_8H_{14}\begin{matrix} \text{C:NO}\cdot\text{CO}\cdot\text{C}_6\text{H}_5 \\ \text{C:N}_2\text{O}_2 \end{matrix}$, prepared from the sodium derivative and benzoyl chloride, dissolved with unexpected difficulty in hot alcohol, from which it crystallises in lustrous, transparent, six-sided prisms, becoming yellow and decomposing at 174° :

0.1792 gave 20.3 c.c. N_2 at 18° and 748 mm. $N=12.87$.

$C_{17}H_{19}O_4N_3$ requires $N=12.62$ per cent.

A solution containing 0.1491 gram, made up to 25 c.c. with chloroform, gave $\alpha_D^{20} 1^{\circ}31'$ in a 3-dm. tube, whence $[\alpha]_D^{20} 84.7^{\circ}$. The substance is readily soluble in chloroform, acetone, ethyl acetate, and warm benzene, sparingly so in boiling petroleum; on adding 20 per cent. sodium hydroxide to the boiling alcoholic solution there is developed the deep yellow coloration of the sodium derivative, showing that the rearrangement leading to the colourless benzoyl derivative of isonitrosocamphor does not occur on benzoylating the pernitroso-compound.

Production of Camphor from Pernitrosocamphor.

Tiemann showed that hydriodic acid removes the pernitroso-group and regenerates camphor (*Ber.*, 1895, 28, 1081), which was recognised also by Angeli and Castellana (*loc. cit.*) in the complex mixture of materials arising from the pernitroso-derivative by reduction; this includes the two isomeric bornylamines, camphoroxime, camphene, camphanazine, nitrous acid, and nitrogen. We find that whilst hydrogen sulphide is without action on pernitrosocamphor in alcoholic solution, addition of ammonia causes the liquid to turn red and evolve gas; evaporation of the alcohol leaves camphor, which is also regenerated easily and quantitatively from the pernitroso-derivative by the action of alcoholic sodium hydroxide. Three grams in 10 grams of alcohol were heated with 2 grams of sodium hydroxide in 8 grams of water during three hours under reflux, when distillation in steam gave the expected quantity of camphor; a control experiment in which camphoroxime was substituted for pernitrosocamphor showed that under the above conditions the oxime undergoes no change. Hence the production of camphor by hydrolysis cannot depend on intermediate formation of camphoroxime.

Aniline also may be used for the recovery of camphor from the pernitroso-derivative, doubtless owing to the production of phenyl-

iminocamphane, $C_8H_{14} \begin{smallmatrix} CH_2 \\ \diagup \\ C:N \cdot C_6H_5 \end{smallmatrix}$, which might be expected to undergo hydrolysis with great facility. When alcoholic solutions are heated, gas is liberated, and after a short interval the liquid gives camphor with hydrochloric acid; another experiment, in which the two materials were left in contact during many months at laboratory temperature, gave crystals of camphor without addition of acid, suggesting that phenyliminocamphane must be a highly unstable substance.

Action of Hydrazine on Pernitrosocamphor.

Angeli and Castellana have shown (*loc. cit.*) that the action of hydrazine on pernitrosocamphor leads to camphanazine, and this we find to be the case if the materials are heated together; the following experiment, however, seems to indicate that this is a secondary product, arising from decomposition of the unstable

camphorhydrazone, $C_8H_{14} \begin{smallmatrix} CH_2 \\ \diagup \\ C:N \cdot NH_2 \end{smallmatrix}$, recently isolated by Kijner

(*J. Russ. Phys. Chem. Soc.*, 1911, 43, 582). Five grams of potassium pernitrosocamphor were covered with hydrazine hydrate

(60 per cent.), and allowed to remain in a stoppered vessel. At first there was not any noticeable change, but gradually the pasty mass became inflated with gas, and in the course of several weeks the crystals disappeared, leaving a viscous oil floating on the liquid. After two months this was extracted with ether, washed with water until the latter was without action on Fehling's solution, and then recovered by evaporating the ether without heat; the viscous residue had an odour resembling that of hornylamine, and reduced ammoniacal silver oxide when heated, whilst oxidation with hot aqueous mercury acetamide led to camphor. The remainder was therefore shaken with benzoyl chloride in 10 per cent. sodium hydroxide, giving rise to camphor benzoylhydrazone (see below), indicating that camphorhydrazone had been produced by the action of hydrazine hydrate on pernitrosocamphor.

On allowing molecular proportions of pernitrosocamphor and benzoylhydrazine to remain a few days in aqueous alcohol, lustrous, silky needles separated, melting at 171° after recrystallisation from methyl alcohol:

0.2006 gave 18.2 c.c. N_2 at 22° and 768 mm. $\text{N} = 10.39$.

$\text{C}_{17}\text{H}_{22}\text{ON}_2$ requires $\text{N} = 10.37$ per cent.

A solution containing 0.3791 gram, made up to 25 c.c. with chloroform, gave $\alpha_D - 1^\circ 32'$ in a 2-dcm. tube, whence $[\alpha]_D - 50.5^\circ$. Whilst freely soluble in cold acetone and chloroform, benzene, alcohol, and ethyl acetate dissolve only moderate proportions, and it is sparingly soluble in boiling petroleum. Concentrated sulphuric acid hydrolyses the substance to camphor, hydrazine, and benzoic acid.

ROYAL COLLEGE OF SCIENCE, LONDON.
SOUTH KENSINGTON, S.W.

CCXXVI.—*The Constituents of the Seeds of Casimiroa edulis.*

By FREDERICK BELDING POWER and THOMAS CALLAN.

THE *Casimiroa edulis*, La Llave and Lejarza (Nat. Ord. *Rutaceae*), is a tree which is widely distributed throughout Mexico and Central America. It is known in Mexico by the vernacular names of "Chochitzapotl" and "Iztactzapotl," and in Guatemala as "Mato sano." Under the title of "Zapote blanco," the Pharmacopœia of Mexico recognises the fruit and the seed of the *Casimiroa*, indicating the former to be used as an anthelmintic and the latter as a vulnerary, for which purpose the kernels of the seed are roasted and powdered. The fruit, as the specific name of the plant denotes, is edible, and has an agreeable flavour, although it is stated to induce sleep, whereas it has been recorded that the kernels of the seed are deleterious or even fatal in their effects (Hernandez, *Rerum medicarum Novae Hispaniae thesaurus*, etc., Romae, 1651, Lib. III., p. 89).

The first chemical investigation of the seed of the *Casimiroa* was by José Sanchez, who, in a thesis published in Mexico in 1893, indicated the presence of a crystalline substance giving the general reactions of an alkaloid, together with two resins, an essential oil, fatty matter, gum, glucose, and starch. The alkaloidal substance was considered to be the probable source of the reputed physiological action of the seed. In 1898 a Commission was appointed in Mexico for the botanical and chemical study of the *Casimiroa*, and for the purpose of determining its therapeutic value. As a result of this inquiry, it was stated by Altamirano that the seed contains a glucoside, which, however, could be obtained only as a pale yellow, amorphous mass. This product, which he regarded as the active principle, possessed a taste which was at first sweet, but afterwards bitter and persistent. It was soluble in water and in alcohol, and its solution yielded precipitates with the usual alkaloid reagents. The results of a subsequent study by Bocquillon, in France, were incorporated in a thesis entitled, "*Étude botanique et pharmacologique des Xanthoxylées-Casimiroa*," 1901, pp. 104, and more recently the subject has been investigated by Bickern (*Arch. Pharm.*, 1903, **241**, 166). A series of pharmacological investigations relating to the *Casimiroa* has furthermore been recorded by Robin and Coyon, by Chevalier, and by Vincent in *Bull. gén. de thérapeutique*, 1909, **158**, 16, 96, 193, 241, the last-mentioned author having also given a complete historical survey of the subject.

The chemical examination of *Casimiroa* seeds by Bickern (*loc. cit.*) was apparently conducted with a very small quantity of material, the amount not being directly stated; but from the results obtained he was led to conclude that they contain a "glucos alkaloid," melting at 106° , to which he assigned the formula "casimirin," and the formula $C_{30}H_{32}O_5N_2$. This formula, however, was based on but one analysis, and its theoretical percentage figures were incorrectly recorded. Nevertheless, the substance was stated to undergo hydrolysis by heating with 30 per cent. hydrochloric acid, with the formation of an alkaloid, $C_{34}H_{54}O_5N_4$, and dextrose, in accordance with the equation:

In this case also a considerable discrepancy in the figures appears to exist, inasmuch as an analysis of the residual alkaloid indicated it to contain 73.2 per cent. of carbon, whereas the formula $C_{34}H_{54}O_5N_4$ requires C=77.3 per cent. It would, moreover, be impossible for a substance of the composition $C_{30}H_{32}O_5N_2$ to yield dextrose on hydrolysis, inasmuch as it contains but five oxygen atoms.

Another compound described by Bickern (*loc. cit.*) was obtained by mixing the powdered seed with lime, and extracting with ether, when, on evaporating the solvent, a colourless substance was precipitated. The latter, when crystallised from chloroform, separated in colourless needles, melting at 207° , and to it the name "casimirol" and the formula $C_{27}H_{44}O_2$ were assigned. As this substance yielded colour reactions similar to those of the phytosterols, it was assumed to be related to that class of compounds.

It was furthermore noted by Bickern that the above-mentioned substances, as well as various ethereal and alcoholic extracts of the seed, were tested on animals by Professor Cloëtta, of Zurich, but were found to be devoid of any hypnotic action. On the other hand, Chevalier (*loc. cit.*, p. 96) was led to conclude from the results of his experiments on animals that the therapeutic value of *Casimiroa* seed is due to the essential oil and resin they contain (compare also *Lancet*, August 21st, 1909, p. 561).

From the preceding brief review of the literature it will be observed that the statements respecting the constituents and physiological action of *Casimiroa* seeds are very divergent, and, to a large extent, inconclusive. In view of the interest pertaining to the subject it was deemed desirable to submit these seeds to a more complete examination, and the results are embodied in the present communication.

EXPERIMENTAL.

Inasmuch as the entire fruit of *Casimiroa edulis* could not conveniently be transported to this country, and the seed are considered to be the most active portion, a quantity of the latter was specially collected in Mexico for the purpose of the present investigation. The seed, which in size and shape somewhat resemble an almond, are provided with a grey, fibrous shell, enclosing a kernel, which is covered with a thin, brown membrane. The shells were found to represent about one-fifth the weight of the entire fresh seed, and they were separately examined.

I.—Examination of the Kernels.

Separation of an Enzyme.

A quantity (810 grams) of the kernels, representing 1 kilogram of the entire seed, was crushed, and macerated with water at the ordinary temperature for two days, the liquid being then expressed and filtered. To the filtered liquid, in which the presence of starch was indicated, about twice its volume of alcohol was added, when an abundant flocculent precipitate was produced. After about twenty-four hours the precipitate was collected, washed with a little alcohol, and dried, first on a porous plate, and finally in a vacuum over sulphuric acid. It could then be reduced to a light brown powder, and amounted to 9 grains, or 0.9 per cent. of the weight of entire seed employed.

The above-described product, when dissolved in water, yielded a solution which frothed strongly on agitation, and gave an abundant, white, curdy precipitate, both with hydrochloric acid and on boiling. It gave the biuret reaction, and also slowly hydrolysed amygdalin, thus proving the presence of an enzyme.

Preliminary Test for an Alkaloid.—A small portion (about 6 grams) of the dried kernels of the seed was treated with Prollius' fluid, and the resulting liquid tested in the usual manner for an alkaloid. The results obtained indicated the presence of a considerable proportion of such a substance.

For the purpose of a complete examination of the seed, the shells were first separated from the kernels, and a quantity of the latter, which, after being ground, amounted to 37.05 kilograms, was extracted by continuous percolation with hot alcohol until exhausted. In view of the asserted presence of a glucoside, or of a "glucoalkaloid," in the seed, and in order to preclude the hydro-

lysis of such a substance, all the preliminary operations were conducted as quickly as possible. After the removal of the greater portion of the alcohol, the amount of thin extract obtained was 11.45 kilograms.

Distillation of the Extract with Steam. Separation of an Essential Oil.

The entire amount of extract was subjected to distillation in a current of steam, and the distillate, which contained some only drops in suspension, extracted with ether. After the removal of the solvent, a quantity (8 grams) of an oily liquid was obtained, which, when distilled under diminished pressure, passed over between 80° and $160^{\circ}/25$ mm., but for the most part below $130^{\circ}/25$ mm. This essential oil, when freshly distilled, had a pale yellow colour, but gradually darkened on keeping, even in absence of air. It possessed an agreeable, aromatic odour, and the following constants: $d = 0.9574$ at 20° ; $n_D - 20^{\circ} 25'$ in a 25 mm. tube. It gave no coloration with ferric chloride, and did not respond to the test for furfuraldehyde.

Non-volatile Constituents of the Extract.

After the above-described operation, there remained in the distillation vessel a dark-coloured aqueous liquid (A), together with a quantity of a soft, oily resin (B). These products were separated, and the resin thoroughly washed with hot water, the washings being added to the main portion of the aqueous liquid.

Examination of the Aqueous Liquid (A).

The aqueous liquid was repeatedly extracted with large quantities of ether, and the ethereal liquid, after concentrating to a convenient bulk, was shaken successively with aqueous ammonium carbonate, sodium carbonate, and sodium hydroxide.

Isolation of a New Alkaloid, Casimirine, $C_{24}H_{20}O_8N_2$.

On shaking the ethereal extract of the aqueous liquid with a concentrated solution of ammonium carbonate, a crystalline substance slowly separated, and remained suspended in the alkaline liquid. This substance was collected, and amounted to 2.8 grams. It crystallised very readily from alcohol or ethyl acetate, separating in rosettes of colourless needles, and melted at $196-197^{\circ}$. Although very sparingly soluble in water, its aqueous solution, when acidified, gave copious precipitates with the usual alkaloidal reagents, such

solutions of iodine in potassium iodide, potassium-mercuric iodide, and picric acid:

0.1170 gave 0.2670 CO_2 and 0.0514 H_2O . $\text{C}=62.2$; $\text{H}=4.9$.

0.1322 „ 7.2 c.c. N_2 at 16° and 768 mm. $\text{N}=6.4$.

$\text{C}_{24}\text{H}_{20}\text{O}_8\text{N}_2$ requires $\text{C}=62.1$; $\text{H}=4.3$; $\text{N}=6.0$ per cent.

These results, together with a subsequent analysis of its aurichloride, indicate the above-described alkaloid to possess the formula $\text{C}_{24}\text{H}_{20}\text{O}_8\text{N}_2$, and, being a new compound, it is proposed to designate it *casimiroine*.

Casimiroine contains two methoxyl groups, as the following determination by Perkins's modification of the Zeisel method has shown:

0.2790 gave 0.2886 AgI. $\text{MeO}=13.6$.

$\text{C}_{22}\text{H}_{14}\text{O}_6\text{N}_2(\text{OMe})_2$ requires $\text{MeO}=13.4$ per cent.

Casimiroine is a very weak base, since it is precipitated from its solution in concentrated hydrochloric acid by dilution with water. The only crystalline salts that could be obtained were the picrate and the aurichloride. The picrate, which was very sparingly soluble, crystallised in small, yellow needles, melting at 165° .

Casimiroine Aurichloride, $\text{C}_{24}\text{H}_{20}\text{O}_8\text{N}_2\cdot\text{HAuCl}_4$.—This salt was prepared by adding a solution of gold chloride to a dilute solution of casimiroine in aqueous alcohol containing a little hydrochloric acid. The yellow precipitate thus produced was crystallised from alcohol, when the salt was obtained in handsome, orange-yellow needles, melting at 195 — 196° :

0.1508 gave 0.1998 CO_2 and 0.0460 H_2O . $\text{C}=36.1$; $\text{H}=3.4$.

0.1207 „ , on ignition, 0.0296 Au. $\text{Au}=24.5$.

$\text{C}_{24}\text{H}_{20}\text{O}_8\text{N}_2\cdot\text{HAuCl}_4$ requires $\text{C}=35.8$; $\text{H}=2.6$; $\text{Au}=24.5$ per cent.

A solution of the alkaloid in chloroform was found to be devoid of optical activity.

When a little casimiroine, on a porcelain tile, is moistened with a drop of concentrated nitric acid, a yellow colour is first produced, which rapidly deepens to orange-red. With concentrated sulphuric acid the alkaloid, when similarly treated, develops a pale green colour, which, on the addition of a trace of nitric acid, immediately changes to a brilliant orange hue.

Hydrolysis of Casimiroine.

Formation of a New Base, Casimiroitine, $\text{C}_{23}\text{H}_{22}\text{O}_7\text{N}_2$.

On boiling casimiroine for several hours with an alcoholic solution of potassium hydroxide, and then adding a small quantity of water, long, glistening, hair-like needles separate from the liquid

on cooling. By the careful fractional crystallisation of this product from ethyl acetate it was observed not to be homogeneous but to consist mainly of a substance which separated in stout prisms, melting at 171° , together with a small quantity of a substance which crystallised in fan-like tufts of slender needles, melting at 159° . Only the first-mentioned substance (m. p. 171°) was obtained in an amount sufficient for analysis. On recrystallising this from dilute alcohol, it was obtained, like the original product, in long, glistening, hair-like needles, which formed a felted mass, greatly resembling glass-wool:

0.2680, dried at 110° to a constant weight, lost 0.0188 H_2O , $\text{H}_2\text{O} = 7.0$.

0.1106 * gave 0.2561 CO_2 and 0.0540 H_2O . $\text{C} = 63.1$; $\text{H} = 5.4$.

0.1560 * " 8.6 c.c. N_2 at 12.5° and 774 mm. $\text{N} = 6.6$.

$\text{C}_{23}\text{H}_{22}\text{O}_7\text{N}_2$ requires $\text{C} = 63.0$; $\text{H} = 5.0$; $\text{N} = 6.4$ per cent.

$\text{C}_{23}\text{H}_{22}\text{O}_7\text{N}_2 \cdot 2\text{H}_2\text{O}$ requires $\text{H}_2\text{O} = 7.6$ per cent.

The above-described hydrolytic product is thus shown to possess the formula $\text{C}_{23}\text{H}_{22}\text{O}_7\text{N}_2$, and, being a new compound, it may be designated *casimiroine*. It appears to have been formed from casimiroine by the addition of a molecule of water and the elimination of a molecule of carbon dioxide, according to the following equation:

When casimiroine is boiled for a few minutes with concentrated hydrochloric acid, it yields an acid which is very sparingly soluble in alcohol and water, and melts above 300° . The amount of material available did not permit of the further study of this reaction.

Isolation of Benzoic Acid.

The ammonium carbonate solution, from which the suspended alkaloid, casimiroine, had been removed by filtration, as already described, was acidified, when a quantity of dark, resinous material was precipitated. As nothing crystalline could be directly isolated from this product, it was dissolved in methyl alcohol, and dry hydrogen chloride passed into the hot solution. The esterified mixture was then poured into water and extracted with ether, the ethereal liquid being subsequently shaken with a dilute solution of sodium hydroxide. The non-phenolic portion of the product possessed the odour of methyl benzoate, and on hydrolysis yielded a small amount of an acid (m. p. 120°), which was identified as benzoic acid. The phenolic portion contained a substance which

* Anhydrous substance.

gave an intense violet coloration with ferric chloride, and was evidently salicylic acid, but the amount of the latter was too small to permit of its isolation.

The original ethereal extract of the aqueous liquid, which had been shaken with a solution of ammonium carbonate, as previously described, was subsequently extracted successively with aqueous sodium carbonate and sodium hydroxide. These alkalis, however, removed only dark-coloured, resinous material, and on finally evaporating the ethereal liquid it left but a slight, oily residue.

Isolation of a New Alkaloid, Casimiroedine, $C_{17}H_{24}O_3N_2$.

The original aqueous liquid, which had been completely extracted with ether, was next shaken repeatedly with hot amyl alcohol. A portion of the amyl-alcoholic extract was concentrated under diminished pressure to a small bulk, when, on cooling, a quantity of dark-coloured, solid material separated. On treating this with a small amount of cold alcohol, most of the colouring matter was removed, leaving a slightly coloured, apparently crystalline substance. After the separation of the latter, no other crystalline substance could be isolated from the dark-coloured material, even after heating it with 5 per cent. sulphuric acid. As the above-mentioned substance was readily soluble in dilute acids, its isolation was found to be most easily effected by shaking the amyl-alcoholic extract with aqueous 2 per cent. sulphuric acid until the acid liquid ceased to give a precipitate with an aqueous solution of iodine in potassium iodide, and the larger remaining portion of the extract was therefore treated in this manner. The sulphuric acid was subsequently removed from the aqueous liquid by means of barium hydroxide, and the excess of the latter by carbon dioxide, after which the liquid was filtered and concentrated. During the process of evaporation the substance separated in the form of crystals, and the total amount so obtained was 16 grams. The substance, which was found to contain nitrogen, was recrystallised from alcohol, when it separated in wart-like aggregates of very small needles, melting at $222-223^{\circ}$:

0.1613 gave 0.3587 CO_2 and 0.0980 H_2O . $C=60.6$; $H=6.8$.

0.1466 „ 10.8 c.c. N_2 at 11° and 743 mm. $N=8.6$.

$C_{17}H_{24}O_3N_2$ requires $C=60.7$; $H=7.1$; $N=8.3$ per cent.

The above-described substance, which has thus been shown to be an alkaloid, evidently possesses the formula $C_{17}H_{24}O_3N_2$. As it is a new compound, it is proposed to designate it *casimiroedine*.

Casimiroedine is a fairly strong base, since it dissolves readily

in dilute acids, and on rendering the solution alkaline the alkaloid only slowly separates in the form of rosettes of needles. It is very sparingly soluble in chloroform, ether, benzene, ethyl acetate, or cold alcohol, but is readily soluble in hot alcohol, and amyl alcohol dissolves it freely.

A slightly acidified solution of casimiroedine, even when exceedingly dilute, gives a reddish-brown precipitate with a solution of iodine in potassium iodide, but potassium-mercuric iodide and picric acid only yield precipitates with a somewhat concentrated solution.

The alkaloid in acid solution was found to be optically active, and a determination of its rotatory power gave the following result:

0.4198, made up to 20 c.c. with 1 per cent. hydrochloric acid, gave $\alpha_D - 1^{\circ}32'$ in a 2-dm. tube, whence $[\alpha]_D - 36.5^{\circ}$.

Casimiroedine was found to contain no methoxyl group, and in its chemical behaviour is a very indifferent substance. No crystalline derivative could be prepared from it with the exception of the aurichloride.

Casimiroedine Aurichloride, $C_{17}H_{24}O_5N_2, HAuCl_4, 2H_2O$.—On the addition of a concentrated solution of gold chloride to a fairly strong solution of casimiroedine in hydrochloric acid the aurichloride is precipitated as an oil, which crystallises on stirring. This salt is dissociated in contact with water, but could be crystallised from 20 per cent. aqueous hydrochloric acid, when it separated in bright yellow, microscopic needles, which melt indefinitely at about 90° in their water of crystallisation. After drying at 70° however, the salt melts and completely decomposes at $145-148^{\circ}$:

0.0984, dried at 100° to a constant weight, lost 0.0054 H_2O
 $H_2O = 5.5$.

0.0930 (dried salt) gave, on ignition, 0.0272 Au. $Au = 29.2$.

$C_{17}H_{24}O_5N_2, HAuCl_4, 2H_2O$ requires $H_2O = 5.1$ per cent.

$C_{17}H_{24}O_5N_2, HAuCl_4$ requires $Au = 29.2$ per cent.

The original aqueous liquid, which had been completely extracted with both ether and amyl alcohol, as already described, was subsequently treated with a slight excess of solution of basic lead acetate. A voluminous, light brown precipitate was thus produced, which was collected, thoroughly washed, and decomposed with hydrogen sulphide, but it yielded nothing definite. The filtrate from the basic lead acetate precipitate was treated with hydrogen sulphide for the removal of the excess of lead, and the filtered liquid concentrated under diminished pressure. It then formed a viscid syrup, which contained a considerable quantity of sugar,

since it readily yielded *d*-phenylglucosazone, melting at 205—207°. A portion of the syrup was heated for two hours with dilute sulphuric acid in a reflux apparatus, and then distilled in a current of steam. The distillate contained traces of formic and acetic acids, and on extracting the liquid remaining in the distillation flask with ether, only a further small amount of these acids was obtained. The aqueous liquid was finally treated with barium hydroxide for the removal of the sulphuric acid, filtered, and concentrated, but no crystalline product separated, even after keeping for a considerable time. There was therefore no evidence that the original aqueous liquid contained any substance of a glucosidic nature.

Examination of the Resin (B).

The resinous material, representing that portion of the alcoholic extract of the kernels of the seed which was insoluble in water, formed a soft, oily mass, and amounted to about 375 grams. It was dissolved in alcohol, mixed with purified sawdust, and the thoroughly dried mixture extracted successively in a Soxhlet apparatus with light petroleum (b. p. 35—50°), ether, chloroform, ethyl acetate, and alcohol.

Petroleum Extract of the Resin.

This extract, after the complete removal of the solvent, was a thin, dark-coloured, oily product, amounting to 256 grams. It was digested with 1 litre of ether, when 3.2 grams of a white, apparently crystalline substance remained undissolved, and were collected. This was resolved by fractional crystallisation from alcohol into a substance which was obtained in the form of needles, melting at 196—197°, and amounting to 1.5 grams, and a substance which melted at 232—233°. The first-mentioned substance consisted of the previously described alkaloid, casimiroine, which had been isolated from the aqueous liquid, whilst the second substance was subsequently obtained in much larger amount from the ethereal extract of the resin, and will be further considered in connexion with the latter.

After the separation of the above-mentioned crystalline substances, the clear ethereal solution of the petroleum extract was shaken with aqueous ammonium carbonate, which, however, removed only traces of resinous material. On subsequently attempting to extract the ethereal liquid with sodium carbonate and sodium hydroxide, intractable emulsions were formed. The ether was therefore removed, and the residue hydrolysed by heating with a

solution of 90 grams of potassium hydroxide in one litre of alcohol. After the removal of the alcohol, water was added, and the alkaline liquid repeatedly extracted with ether.

Isolation of Sitosterol, $C_{27}H_{46}O, H_2O$.

The ethereal extract of the alkaline liquid was dried, and the solvent evaporated. A pale yellow, crystalline product was thus obtained, which was dissolved in hot alcohol, when, on cooling, a quantity (8.8 grams) of a substance separated in colourless plates. On recrystallising the substance from a mixture of ethyl acetate and dilute alcohol, it was obtained in needles, melting at $134-135^\circ$.

0.2263, on heating at 100° , lost $0.0114 H_2O$. $H_2O = 5.0$.

0.1048 * gave $0.3218 CO_2$ and $0.1153 H_2O$. $C = 83.7$; $H = 12.2$.

$C_{27}H_{46}O, H_2O$ requires $H_2O = 4.5$ per cent.

$C_{27}H_{46}O$ requires $C = 83.9$; $H = 11.9$ per cent.

The substance was thus identified as a phytosterol, and it gave the colour reactions of that class of compounds.

A determination of its optical rotatory power gave the following result:

0.3118, * made up to 20 c.c. with chloroform, gave $\alpha_D - 1.90'$ in a 2-dm. tube, whence $[\alpha]_D - 32.1^\circ$.

The phytosterol gave an acetyl derivative, which separated from acetic anhydride in small needles, melting at $126-127^\circ$. Its identity with sitosterol was therefore established.

The original alcoholic mother liquor remaining from the crystallisation of the sitosterol was evaporated, when a quantity (10 grams) of viscid, oily material was obtained. This was found to consist chiefly of oxygenated substances, but nothing definite could be isolated from it.

Isolation of Ipuranol, $C_{22}H_{38}O_2(OH)_2$.

The alkaline liquid, from which the sitosterol had been removed by extraction with ether, was acidified, and the liberated fatty acid taken up with ether. The ethereal liquid contained a quantity of a dark-coloured, crystalline substance in suspension. This was collected, heated with alcohol for the removal of colouring matter, and then recrystallised from dilute pyridine, from which it separated in microscopic needles, melting at $280-285^\circ$. The amount of substance so obtained was 2.9 grams. (Found, $C = 72.6$; $H = 10.4$. Calc., $C = 72.6$; $H = 10.5$ per cent.)

* Anhydrous substance.

The above results, together with the colour reactions yielded by this substance, established its identity as ipuranol.

When heated with acetic anhydride it gave diacetylipuranol, which separated from alcohol in shining leaflets, melting at 166° . (Found, C=69.7; H=9.5. Calc., C=69.8; H=9.5 per cent.)

On heating the ipuranol, in pyridine solution, with benzoyl chloride, a *dibenzoyl* derivative was obtained, which, after crystallisation from a mixture of ethyl acetate and alcohol, separated in needles melting at 197° .

A determination of the optical rotatory power of the ipuranol gave the following result:

0.1708, made up to 20 c.c. with pyridine, gave $\alpha_D -0^{\circ}41'$ in a 2-dcm. tube, whence $[\alpha]_D -40.0^{\circ}$.

Identification of the Fatty Acids.

The ethereal liquid from which the ipuranol had been removed, as above described, was evaporated to a low hulk, and a large quantity of light petroleum added. This precipitated some resinous material, which was separated, after which the liquid was again evaporated. A quantity (105 grams) of fatty acids was thus obtained, which, when distilled under diminished pressure, passed over between 200° and $230^{\circ}/12$ mm.

In order to effect a separation of the solid and liquid acids, a portion (25 grams) of the mixture was converted into the lead salts, and the latter digested with ether, when the greater part dissolved. Both the soluble and insoluble portions were decomposed by hydrochloric acid, and the liberated fatty acids separately examined.

The Liquid Acids.—These acids, when distilled under diminished pressure, passed over between 235° and $250^{\circ}/15$ mm. as a yellow oil. An analysis and determination of the constants gave the following results:

0.1026 gave 0.2906 CO_2 and 0.1099 H_2O . C=77.2; H=11.9.

0.2646 absorbed 0.4120 iodine. Iodine value=155.7.

0.3094 neutralised 0.0621 KOH. Neutralisation value=200.7.

$\text{C}_{18}\text{H}_{34}\text{O}_2$ requires C=76.6; H=12.1 per cent. I.V.=90.1;
N.V.=198.9.

$\text{C}_{18}\text{H}_{32}\text{O}_2$ requires C=77.1; H=11.4 per cent. I.V.=181.4;
N.V.=200.4.

$\text{C}_{18}\text{H}_{30}\text{O}_2$ requires C=77.7; H=10.8 per cent. I.V.=274.1;
N.V.=201.8.

These results would indicate that the liquid acids consist of a mixture of oleic, linolic, and linolenic acids.

The Solid Acids.—These acids, when crystallised from glacial acetic acid, separated in glistening leaflets, melting at 60–62°:

0.1030 gave 0.2875 CO₂ and 0.1194 H₂O. C=76.1; H=12.9.
 0.2292 neutralised 0.0461 KOH. Neutralisation value=201.1.
 C₁₆H₃₂O₂ requires C=75.0; H=12.5 per cent. N.V.=219.1.
 C₁₈H₃₆O₂ „ C=76.1; H=12.7 „ „ N.V.=197.5.

The solid acids would thus appear to consist of a mixture of palmitic and stearic acids, the latter predominating.

Ethereal Extract of the Resin.

This extract, after the removal of the solvent, formed a brittle mass, which could readily be reduced to a light brown powder, and amounted to 75 grams. It was heated with 2 litres of alcohol when the greater portion dissolved. The small insoluble portion (2.3 grams) was collected, and identified as ipuranol.

Isolation of a New Lactone, Casimirolid, C₂₄H₂₈O₆.

The above-mentioned hot alcoholic liquid deposited on cooling a quantity (22.1 grams) of well-developed crystals, which, when recrystallised from alcohol with the addition of a little animal charcoal, separated in colourless prisms, melting at 229–230°:

0.0960 gave 0.2448 CO₂ and 0.0594 H₂O. C=69.5; H=6.9.
 0.1326, in 21.16 benzene, gave Δt = 0.072°. M.W.=426.
 C₂₄H₂₈O₆ requires C=69.9; H=6.8 per cent. M.W.=412.

From these results it is evident that the above-described substance possesses the formula C₂₄H₂₈O₆, and that it is a new compound. Having ascertained that it is a lactone, as shown below, it is proposed to designate it *casimirolid*.

Casimirolid is readily soluble in ether, chloroform, and ethyl acetate. It is optically active, and a determination of its specific rotatory power gave the following result:

0.3856, made up to 25 c.c. with chloroform, gave α_D = -1°31' in a 2-dm. tube, whence $[\alpha]_D$ = -49.2°.

Hydrolysis of the Lactone.

Formation of a New Hydroxy-acid, Casimiroic Acid, C₂₃H₂₈O₄(OH)·CO₂H.

When casimirolid is shaken with a cold solution of potassium hydroxide in aqueous alcohol, it readily takes up a molecule of water, and is converted into an acid, which is precipitated on acidifying the alkaline liquid. This acid crystallises very readily from alcohol in rosettes of glistening needles, melting at 207°:

0.1074 gave 0.2638 CO_2 and 0.0698 H_2O . $\text{C}=67.0$; $\text{H}=7.2$.

0.2792 neutralised 0.0359 KOH . $\text{M.W. (monobasic acid)}=436$.

$\text{C}_{24}\text{H}_{30}\text{O}_7$ requires $\text{C}=67.0$; $\text{H}=7.0$ per cent. $\text{M.W.}=430$.

The above-described acid is thus shown to possess the formula $\text{C}_{24}\text{H}_{30}\text{O}_7$. Like the corresponding lactone, it is a new compound, and it is proposed to designate it *casimiroic acid*.

A determination of the optical rotatory power of the acid gave the following result:

0.1670, made up to 20 c.c. with absolute alcohol, gave $\alpha_D -1.027'$ in a 2-dcm. tube, whence $[\alpha]_D -86.8^\circ$.

Casimiroic acid, unlike the lactone, is very sparingly soluble in ether, chloroform, and ethyl acetate. Its sodium salt is very readily soluble in water and in alcohol. On the addition of a solution of copper sulphate to a neutral solution of the sodium salt, a pale blue, amorphous precipitate of copper casimiroate was produced, the analysis of which, however, indicated it to consist of a basic salt.

Silver Casimiroate, $\text{C}_{23}\text{H}_{29}\text{O}_5 \cdot \text{CO}_2\text{Ag}$.—This salt was obtained as a white, amorphous precipitate on the addition of a solution of silver nitrate to a solution of the sodium salt. It is sparingly soluble in water, and gradually darkens on exposure to light:

0.1435 of salt gave, on ignition, 0.0296 Ag . $\text{Ag}=20.6$.

$\text{C}_{24}\text{H}_{29}\text{O}_7\text{Ag}$ requires $\text{Ag}=20.1$ per cent.

Methyl Casimiroate, $\text{C}_{23}\text{H}_{29}\text{O}_5 \cdot \text{CO}_2\text{CH}_3$.—This ester was prepared by passing dry hydrogen chloride into a solution of the acid in methyl alcohol at the boiling temperature. It was very soluble in alcohol, and could only be obtained with difficulty in a crystalline state from dilute alcohol, when it melted at $108-110^\circ$:

0.1086 gave 0.2666 CO_2 and 0.0739 H_2O . $\text{C}=66.9$; $\text{H}=7.6$.

$\text{C}_{23}\text{H}_{32}\text{O}_7$ requires $\text{C}=67.5$; $\text{H}=7.2$ per cent.

Acetylcasimiroic Acid, $\text{C}_{23}\text{H}_{28}\text{O}_4(\text{O} \cdot \text{CO} \cdot \text{CH}_3) \cdot \text{CO}_2\text{H}$.—This was obtained by heating casimiroic acid with acetic anhydride, pouring the product into water, and digesting the resulting precipitate with dilute aqueous sodium carbonate, when, on acidifying the alkaline liquid, the *acetyl* derivative was precipitated. It was exceedingly soluble in the usual organic solvents, but could be obtained from dilute alcohol in colourless, microscopic needles. The acetyl derivative has no sharp melting point, but gradually decomposes at temperatures above 142° :

0.1149 gave 0.2774 CO_2 and 0.0738 H_2O . $\text{C}=65.8$; $\text{H}=7.1$.

$\text{C}_{26}\text{H}_{32}\text{O}_8$ requires $\text{C}=65.8$; $\text{H}=6.8$ per cent.

Isolation of a Yellow Phenolic Substance, C₁₆H₁₂O₆

After the separation of the lactone, casimiroid, from the alcoholic solution of the ethereal extract of the resin, as previously described, the solvent was removed, and the residue, which still contained a small amount of lactone, dissolved in ether. The ethereal liquid was then successively extracted with solutions of ammonium carbonate, sodium carbonate, and sodium hydroxide. The ammonium carbonate removed only a small amount of resinous substance, from which nothing definite could be isolated. The sodium carbonate extract also consisted chiefly of resinous material, but by digesting the latter with alcohol, in which the resin was very soluble, a small amount (0.15 gram) of a crystalline substance was isolated. This substance, when recrystallised from dilute alcohol, separated in small, yellow needles, melting at 215–218°. Its solution gave a yellow colour with alkalis and with ferric chloride. With concentrated sulphuric acid it yielded an orange-red solution, slowly changing to pale yellow, but showing no fluorescence:

0.0816 gave 0.1904 CO₂ and 0.0290 H₂O. C=63.6; H=3.9.

C₁₆H₁₂O₆ requires C=64.0; H=4.0 per cent.

The substance thus appears to possess the formula C₁₆H₁₂O₆, but the amount available did not permit of its further characterisation. Although isomeric with the flavone derivatives, kœmpferid (*Ber.*, 1881, 14, 2385) and the luteolin monomethyl ether prepared synthetically by Diller and Kostanecki (*Ber.*, 1901, 34, 1452), it is not identical with either of these compounds.

The sodium hydroxide extract of the above-mentioned ethereal liquid yielded on acidification a quantity (4.2 grams) of a crystalline substance, which, when recrystallised from alcohol, separated in glistening needles, melting at 207°. This substance was identified as the previously described casimiroic acid, which had evidently been formed by the action of the alkali on the lactone present in the ethereal liquid. After the successive extraction of the ethereal liquid with the above-mentioned alkalis, the solvent was evaporated, but only a slight, oily residue remained.

Chloroform, Ethyl Acetate, and Alcohol Extracts of the Resin.

The chloroform extract of the resin formed a hard, black mass, and amounted to 18.6 grams. The only crystalline substance obtained from it was a small quantity (0.6 gram) of the previously described alkaloid, casimiroine. The ethyl acetate and alcohol

extracts were dark-coloured products, and amounted to 3.2 and 22 grams respectively. Both of these extracts were heated with 5 per cent. sulphuric acid in aqueous alcohol, but they yielded nothing definite, although the aqueous liquid resulting from this treatment of the alcohol extract evidently contained some sugar, for it readily reduced Fehling's solution, and from the liquid, after the removal of the sulphuric acid, a little *d*-phenylglucosazone (m. p. 206°) was prepared.

II.—*Examination of the Shells.*

A small portion (10 grams) of the ground shells was subjected to a preliminary test for an alkaloid by digestion with Prollius' fluid. The reactions obtained were much less marked than in the case of the kernels, but indicated the presence of a small amount of alkaloidal substance.

Another portion (50 grams) of the ground material was successively extracted with various solvents, when the following amounts of extract, dried at 100°, were obtained:

Petroleum (b. p. 35–50°)	extracted	0.2 gram	= 0.4 per cent.
Ether	"	0.3 "	0.6 "
Chloroform	"	0.1 "	0.2 "
Ethyl acetate	"	0.1 "	0.2 "
Alcohol	"	0.8 "	1.6 "

Total..... 1.5 grams = 3.0 per cent.

For a complete examination of the shells a quantity (10.39 kilograms) of the ground material was completely extracted with hot alcohol. After the removal of the greater portion of the solvent, a thin extract, amounting to 482 grams, was obtained.

The whole of the above-mentioned extract was first distilled in a current of steam, when it yielded a very small amount (0.65 gram) of an essential oil. This oil appeared to be similar in character to that obtained from the kernels of the seed, but the amount was not sufficient for its further examination.

The aqueous liquid and resinous material remaining after the above-described treatment of the extract were examined by methods similar to those described in connexion with the kernels of the seed.

The chief constituents of the aqueous liquid were found to be amorphous colouring matter and sugar, the latter yielding *d*-phenylglucosazone, melting at 206°. No other crystalline product could be obtained from the liquid, the amount of alkaloidal substance present having proved to be too small to permit of its isolation.

The resinous material, when thoroughly washed and dried, formed a light brown, friable mass, and amounted to 95 grams, or about 0.9 per cent. of the weight of shells employed. The resin was

successively extracted with various solvents, and the resulting products separately examined. The petroleum extract, which amounted to 37 grams, contained a considerable quantity (20 grams) of stearic acid in a free state, together with a little free palmitic acid, and a small amount of these acids in the form of glycerides. The stearic acid, when crystallised from alcohol, separated in pearly leaflets, melting at $67-68^{\circ}$. (Found, $C=76.2$; $H=13.1$. Calc. $C=76.1$; $H=12.7$ per cent.) The ether, chloroform, ethyl acetate, and alcohol extracts of the resin amounted to 8.8, 30.4, 1.5, and 14.5 grams respectively, and consisted entirely of amorphous products. The chloroform and alcohol extracts were heated with 5 per cent. sulphuric acid in aqueous alcohol, but as they yielded no sugar by this treatment, they were not glucosidic in character.

Physiological Tests.

In order to ascertain whether either the hypnotic or toxic action attributed to *Casimiroa* seed (*loc. cit.*) could be confirmed, a number of tests were kindly conducted for us at the Wellcome Physiological Research Laboratories by Drs. H. H. Dale and P. P. Laidlaw, to whom our best thanks may here be expressed. All the products, with the exception of the essential oil, as noted below were administered to dogs by the mouth.

The finely-divided kernel of an entire seed, weighing about 2 grams, as also 1 gram of the dry enzyme or protein material obtained from the seed, and representing 90 grams of the kernel had no effect. One gram of the alcoholic extract, representing 3.2 grams of the kernels of the seed, produced vomiting and a temporary depression, which was apparently due to the repeated emesis, but no other effect could be observed. A similar effect was produced by the administration of 1 gram each of the petroleum and alcohol extracts of the resin, whereas the ether, chloroform and ethyl acetate extracts of the resin were inactive. The following crystalline substances which had been isolated from the seed namely, casimiroine, $C_{21}H_{30}O_8N_2$, casimiroedine, $C_{17}H_{24}O_8N_2$, and the lactone, casimiroliol, $C_{24}H_{38}O_6$, were given to dogs in amounts of 0.4 gram, and also to cats in doses of 0.1 gram respectively, but the animals remained perfectly normal. Inasmuch as the experiments of Chevalier (*loc. cit.*) led him to conclude that the therapeutic value of *Casimiroa* seed is due to the essential oil or the resin which he presumed to be produced therefrom, a special test was conducted with the essential oil. A quantity (0.25 c.c.) of this product representing about 1100 grams of the kernels of the seed when given to a cat, produced salivation and slight depression.

which may be ascribed to the nauseating taste of the substance, but there was no further effect, and particularly no trace of narcosis.

Summary.

The material employed for this investigation consisted of the fresh seeds of *Casimiroa edulis*, La Llave and Lejarza (Nat. Ord. Rutaceae), which were obtained directly from Mexico.

For the purpose of their examination, the kernels of the seed were first separated from the dry, fibrous shells. The latter, which represented about one-fifth the weight of the entire fresh seed, were separately examined, but yielded little of interest. They were found to contain a small amount of an essential oil, traces of alkaloidal substance, some sugar, and considerable stearic acid in the free state, together with resinous material.

The kernels of the seed, when subjected to a preliminary test, gave reactions indicating the presence of a considerable proportion of an alkaloid. They were also found to contain an enzyme, which was obtained in the form of a light brown powder, and slowly effected the hydrolysis of amygdalin.

An alcoholic extract of the ground kernels, when distilled in a current of steam, yielded a small amount of a pale yellow essential oil, which gradually darkened in colour. This oil had an agreeable, aromatic odour, and the following constants: $d = 0.9574$ at 20° ; $n_D^{20} = 1.5251$ in a 25 mm. tube.

From the portion of the extract which was soluble in water there were isolated: (i) a new alkaloid, *casimiroine*, $C_{24}H_{20}O_8N_2$ (m. p. $196-197^\circ$), which is a very weak base, but yields a crystalline *picrate* (m. p. 165°) and an *aurichloride* (m. p. $195-196^\circ$). On heating casimiroine with alkalis, it undergoes hydrolysis, with the elimination of carbon dioxide, yielding a new base, *casimiroitine*, $C_{22}H_{18}O_7N_2$ (m. p. 171°), together with a small amount of a basic substance melting at 159° ; (ii) a new alkaloid, *casimiroedine*, $C_{22}H_{20}O_8N_2$ (m. p. $222-223^\circ$; $[\alpha]_D$, in acid solution, -36.5°), which yields a crystalline *aurichloride*; (iii) benzoic acid, with apparently a trace of salicylic acid. The aqueous liquid contained, furthermore, a quantity of sugar, which yielded *d*-phenylglucosazone (m. p. $205-207^\circ$).

The portion of the alcoholic extract which was insoluble in water consisted of a soft, oily resin. From this material the following compounds were isolated: (i) sitosterol, $C_{27}H_{46}O$ (m. p. $134-135^\circ$; $[\alpha]_D -32.1^\circ$); (ii) ipuranol, $C_{23}H_{38}O_2(OH)_2$; (iii) a mixture of fatty acids, consisting of palmitic, stearic, oleic, linolic, and linolenic acids; (iv) a new lactone, *casimirolid*, $C_{24}H_{28}O_6$ (m. p. $229-230^\circ$; $[\alpha]_D -49.2^\circ$), which yields a new hydroxy-acid, designated as

casimiroic acid, $C_{23}H_{39}O_4(OH) \cdot CO_2H$ (m. p. 207° ; $[\alpha]_D -86.8^\circ$). The following derivatives of this acid were prepared: *silver casimiroate*, $C_{23}H_{39}O_5 \cdot CO_2Ag$; *methyl casimiroate*, $C_{23}H_{39}O_5 \cdot CO_2CH_3$ (m. p. $108-110^\circ$); and *acetylcasimiroic acid*,

(v) a yellow, phenolic *substance*, $C_{16}H_{15}O_6$ (m. p. $215-218^\circ$).

It may finally be noted that the results of the present investigation of *Casimiroa* seed have afforded no evidence of the presence of a definite glucoside or a so-called "glucoalkaloid," as has previously been affirmed, and physiological tests conducted with animals have likewise failed to confirm their reputed hypnotic or toxic properties.

CXXXVII. *Komppa's Synthesis of Camphoric Acid.*

By GUSTAVE LOUIS BLANC and JOCELYN FIELD THORPE.

The publication of Komppa's reply to our criticism respecting his synthesis of camphoric acid (this vol., p. 29) has led us to investigate the action of very dilute alkali on methyl diketocamphorate (I). Under these conditions the compound is converted into the alkali salt of the dibasic acid, which eliminates carbon dioxide when acidified, and yields the monobasic acid (II). This substance passes into the diketone (III) when it is heated at 160° :

The lower homologue of this diketone (IV) is prepared by distilling methyl diketocamphorate with dilute sulphuric acid:

The two diketones were characterised by the formation of the osazones and dioximes.

There is, then, no question that under the experimental conditions used by Komppa for the reduction of methyl diketocamphorate* the methyl group remains attached to carbon; our criticism of his synthetic formation of camphoric acid is therefore baseless.

EXPERIMENTAL.

3:4-Diketo-1:1:2-trimethylcyclopentane-5(or 2)-carboxylic Acid,

Five grams of methyl diketocamphorate were dissolved in a solution containing rather more than the theoretical amount of potassium hydroxide in ten times its weight of water, and allowed to remain at the ordinary temperature for twenty-four hours; the solution was then evaporated in a desiccator to half its volume, and acidified by hydrochloric acid. Carbon dioxide was eliminated, and the monobasic acid slowly separated; it was recrystallised from water at 50°, and obtained in small, flattened needles, melting at 146°, with immediate evolution of carbon dioxide:

0.2267 gave 0.4864 CO₂ and 0.1289 H₂O. C=58.51; H=6.37.

C₈H₁₂O₄ requires C=58.7; H=6.5 per cent.

3:4-Diketo-1:1:2-trimethylcyclopentane,

This diketone is formed when the above acid is heated in a bath of sulphuric acid at 160° until carbon dioxide ceases to be evolved. It crystallises from water containing a little alcohol in long, silky needles, which melt at 83°:

0.2098 gave 0.5260 CO₂ and 0.1620 H₂O. C=68.42; H=8.61.

C₈H₁₂O₂ requires C=68.6; H=8.6 per cent.

Like the similar compounds investigated by Dieckmann (*Ber.*, 1902, 35, 3208), this substance is largely, if not entirely, enolic in structure; thus it gives a violet coloration with ferric chloride, and readily dissolves in aqueous potassium hydroxide, yielding a potassium salt, which is sparingly soluble in excess of alkali. It reacts, however, towards phenylhydrazine and hydroxylamine as a diketone.

The *osazone*, prepared in acetic acid solution, separates from alcohol containing a little water in small, yellow prisms, which melt at 162°:

0.1507 gave 22.1 c.c. of N₂ at 14° and 747 mm. N=17.2.

C₂₀H₂₄N₄ requires N=17.5 per cent.

The *dioxime* separates after some days from a solution of the diketone and hydroxylamine hydrochloride in dilute alcohol containing the theoretical amount of potassium hydroxide. It crystallises from dilute alcohol in long, slender needles, which melt and decompose at 172° :

0.1200 gave 0.2476 CO_2 and 0.0907 H_2O . $\text{C}=56.32$; $\text{H}=8.21$
 $\text{C}_3\text{H}_{14}\text{O}_2\text{N}_2$ requires $\text{C}=56.3$; $\text{H}=8.4$ per cent.

The diketone is soluble in water, and when pure can be recrystallised from this solvent; the aqueous solution is neutral to litmus. It completely sublimes at 70° without melting.

3:4-Diketo-1:1-dimethylcyclopentane,

The preparation of this substance can be effected by boiling methyl diketoapocamphorate with dilute sulphuric acid (one of acid to three of water) for three hours, and distilling the product with steam. The diketone passes over as an oil, which boils at 197° 748 mm., and yields a distillate, which solidifies to a mass of needles on cooling. It melts at 45° , and is readily soluble in all organic solvents:

0.2279 gave 0.5541 CO_2 and 0.1591 H_2O . $\text{C}=66.52$; $\text{H}=7.83$.
 $\text{C}_7\text{H}_{10}\text{O}_2$ requires $\text{C}=66.7$; $\text{H}=7.9$ per cent.

The *osazone*, prepared in acetic acid solution, separates as an oil which resinifies on keeping. It can be obtained crystalline by rubbing with alcohol, and recrystallising from this solvent; it forms yellow needles, melting at 167° :

0.1355 gave 21.4 c.c. of N_2 at 16° and 746 mm. $\text{N}=18.32$.
 $\text{C}_{10}\text{H}_{12}\text{N}_4$ requires $\text{N}=18.3$ per cent.

The enolic structure of this diketone is apparent from the fact that it gives a deep wine-red colour with ferric chloride, and dissolves in aqueous potassium hydroxide, yielding a solution from which excess of alkali precipitates the potassium salt in glistening plates. The potassium salt is readily soluble in water, and the solution deposits the diketone when acidified. The aqueous solution of the diketone is faintly acid to litmus.

CCXXVIII.—*The Lower Limit of Inflammation of Mixtures of the Paraffin Hydrocarbons with Air.*

By MAURICE JOHN BURGESS and RICHARD VERNON WHEELER.

WHEN a source of heat, such as a lamp flame or an electric spark, is introduced into a mixture of a combustible gas and air, two things are necessary to ensure propagation of flame throughout that mixture.

Supposing that too small a proportion of combustible gas is present, only a small quantity of heat per unit volume of mixture is liberated when the layer surrounding the initial source of heat is inflamed, and the products of combustion have to impart heat to a considerable volume of "inert" gases. The number of collisions between molecules of combustible gas and of oxygen that are chemically fruitful is therefore small. Such collisions, resulting in combination, will occur only in the neighbourhood of the initial source of heat, around which an aureole or "cap" will form of a size dependent on the nature and quantity of the combustible gas present.

As the proportion of combustible gas is increased, a greater quantity of heat is evolved per unit volume of mixture, and a smaller volume of inert gases is present to absorb it; until a point is reached when the amount of heat contained in the products of combustion of any given layer is just sufficient to raise to its ignition-temperature* the layer adjacent. Flame is then propagated from layer to layer throughout the mixture without any necessity for the continued presence of the source of heat which started the inflammation, and the mixture is said to "inflare" or "explode" according to the rapidity of the propagation.

To ensure propagation of flame, therefore, it is necessary (1) that the initial source of heat should be of a volume, intensity, and duration sufficient to raise the layer of gases in its immediate vicinity to a temperature higher than, or as high as, the ignition-temperature of the mixture; and (2) that the heat contained in the products of combustion of this first layer should be sufficient to raise the adjacent layer to its ignition-temperature.

The smallest quantity of any combustible gas which, when mixed with a given quantity of air (or oxygen), will enable this self-propagation of flame to take place, is termed the *lower limit of inflammation* of the gas.

* By "ignition-temperature" we mean, accepting Nernst's definition, that temperature at which rapid self-heating of the mixture takes place.

Similarly, there is a *higher limit* of inflammation corresponding with the greatest quantity of inflammable gas, or, rather, with the smallest quantity of oxygen, that will allow self-propagation of flame. The experimental part of this paper deals only with the lower limit.

The first systematic determinations of the limits of inflammation were made in 1816 for "firedamp" by Davy, who thus describes them ("Collected Works," Vol. VI., p. 24): "When 1 part of firedamp was mixed with 1 of air, they burnt by the approach of a lighted taper, but did not explode; 2 of air and 3 of air to 1 of gas produced similar results. When 4 of air and 1 of gas were exposed to a lighted candle, the mixture being in the quantity of 6 or 7 cubical inches in a narrow-necked bottle, a flame descended through the mixture, but there was no noise; 1 part of gas inflamed with 6 parts of air in a similar bottle, produced a slight whistling sound; 1 part of gas with 9 parts of air, rather a louder sound, 1 part with 10, 11, 12, 13, and 14 parts, still inflamed, but the violence of combustion diminished. In 1 part of gas and 15 parts of air, the candle burnt without explosion with a greatly enlarged flame; and the effect of enlarging the flame, but in a gradually diminishing ratio, was produced as far as 30 parts of air to 1 of gas."

These experiments, therefore, place the lower limit of inflammation of the particular sample of "firedamp" that Davy used at between 6.3 and 6.7 per cent.

Davy's determinations were repeated in 1876 by Coquillion (*Compt. rend.*, 1876, 83, 709), who ignited the mixture in a closed vessel by means of an electric spark. His results, and his description of them, are similar to Davy's, but he places the lower limit at about 5.8 per cent.

Later determinations of the limits of inflammation of "firedamp, and of a number of pure gases and vapours, have been made by Le Chatelier, in conjunction with Mallard (*Ann. des Mines*, 1883, 54) and Boudouard (*Compt. rend.*, 1898, 126, 1344 and 1510). The figure given for firedamp (assumed to be pure methane) is 6.0 per cent. This figure has received general acceptance throughout the coal-mining world, to which it is, of course, of paramount importance.

The most recent results that have come to our notice are those published by Teclu (*J. pr. Chem.*, 1907, [ii], 75, 212). Teclu states that the lower limit of inflammation of methane, prepared from sodium acetate, lies between 3.20 and 3.67 per cent.*

* Since this was written a letter from Dr. E. P. Perman has appeared in the correspondence columns of *Nature* (September 28th, 1911) entitled "Limits of

In connexion with the work on coal-dust explosions on which we have been engaged for the Mining Association of Great Britain, it was essential that we should know with certainty what was the smallest amount of firedamp which, when present in dust-free air at ordinary temperature and pressure, would enable flame to be propagated when a source of heat was introduced. Techn's results differed so widely from those generally accepted that we found it necessary to make fresh determinations under conditions which would as far as possible eliminate sources of error such as cooling by the walls of the vessel in which the inflammable mixtures were ignited. Moreover, we had reason to believe that "firedamp" should not be regarded as consisting of pure methane, or methane diluted with a greater or lesser quantity of air, but that in many samples other hydrocarbons are present in appreciable (and by no means negligible) quantities.

In this connexion Davy says (*loc. cit.*, p. 14): "Though all the specimens of firedamp which I have examined consisted of carburetted hydrogen mixed with different small percentages of carbonic acid and common air, yet some phenomena that I observed in the combustion of a blower induced me to believe that small quantities of olefient gas may be sometimes evolved in coal mines with the carburetted hydrogen."

A full discussion of the probable composition of firedamp as it exists in coal mines appears in a paper by Gray (*Trans. Inst. Mining Eng.*, 1910, 39, 286), who points out that although methane is the only inflammable gas that has been reported as contained in firedamp in the large number of analyses that have been made in the last few years, yet since the proportion of firedamp in the atmosphere of a well-ventilated mine is usually small, it is quite likely that the relatively much smaller proportion of other inflammable gases has escaped recognition; and he places on record the analysis of a sample which contained noteworthy quantities of

Explosibility in Gaseous Mixtures." Dr. Perman states that he has obtained much wider limits than those usually given, and he gives for methane 2.5 per cent. as the lower limit of explosibility (inflammation) when mixed with air. Ignition was effected by means of an incandescent platinum wire, the experiments being carried out in a glass tube of about 10 c.c. capacity, having a stopcock at each end and a mercury gauge of small bore attached to the middle of the tube. Dr. Perman says: "when the explosion occurs the mercury moves more or less sharply, according to the force of the explosion, but a distinct movement, apart from that due merely to the expansion caused by the beating of the wire, can be seen with the proportions of gases given above." From the fact that a "distinct movement" of the mercury gauge could be observed, it does not necessarily follow that the mixture experimented with was explosive or even inflammable. The expansion caused by the heat of combustion of only a trace of inflammable gas would be sufficient to affect a sufficiently delicate gauge.

higher paraffins. If it is assumed that ethane was the only paraffin hydrocarbon present beside methane in this particular sample of firedamp, Gray's analysis shows that the combustible gas contained 55.5 per cent. of methane and 44.5 per cent. of ethane, the proportions present in the air mixture being 1.84 and 1.47 per cent. respectively.

Further, when it is remembered that the major portion of the inflammable gases that find their way into the ventilating current of coal mines issues from minute fissures in the coal,* and that the gases that can be extracted from coal at the ordinary temperature, either by exhaustion or by simply crushing, contain not only ethane but higher members of the paraffin series of hydrocarbons, it will be seen that the limits of inflammability of every sample of "firedamp" must not be regarded as identical with those of any one particular sample.

These considerations prompted us to determine the lower limit of inflammation of the higher members of the paraffin series of hydrocarbons when mixed with air, as well as that of methane. At the same time it appeared that it should be possible, by obtaining a sufficiency of data, to establish some definite relationship between the lower limit of inflammation of any gas and its known physical properties.

A "lower-limit mixture" is one such that a given volume must, under the conditions of its combustion, evolve just sufficient heat to raise an equal volume to its ignition-temperature. There are at least three factors which must obviously determine this necessary condition: (1) the calorific power of the gas; (2) the relative volume and specific heat of the diluent gases; and (3) the ignition-temperature of the mixture.

Of these three factors the first must undoubtedly exercise the preponderating influence; for, taking the paraffin series of hydrocarbons, C_nH_{2n+2} , when n is small the calorific value of the gas is much less than when n is large; so that, a priori, the higher the value of n the less volume of the gas need be present in air to form a lower-limit mixture. This means also that the higher the value of n the greater the volume of diluent gases present per unit volume of mixture. On the other hand, as is indicated by the determinations made by Dixon and Coward (*Trans.*, 1909, 95, 514), the

* Many investigations have been made regarding the nature of the gases that are contained in coal after it has been mined, when, presumably, considerable escape of gas has already occurred. Amongst the most important are those by von Meyer (*J. pr. Chem.*, 1872, [iii], 5, 144, 407, 6, 360), Thomas (*Journ. Chem. Soc.*, 1875, 23, 793), and Bedson and McConnell (*Trans. Fed. Inst. Min. Eng.*, 1892, 3, 307). More recently Porter and Owitz (*U.S. Bureau of Mines, Tech. Paper*, 2, 1911) have conducted experiments with freshly-mined coal, and give some remarkable figures for the rate of escape of gases therefrom when crushed.

ignition-temperatures of the paraffin hydrocarbons appear to fall slightly as the series is ascended.

The effect of an increase in these two last-named factors is small in comparison with the effect of the increased calorific value of the gas, and they operate in a contrary direction.

As a first approximation, therefore, it would appear probable that the lower limit of inflammation should vary inversely as the calorific value of the gas; that is to say, if L = the proportion of the combustible gas necessary to form a lower limit mixture, and C = its calorific value,

$$L = f(1/C), \text{ or, say, } L = k/C \quad (1),$$

where k is a constant, the meaning of which will be considered later. Before considering its probable meaning, it will be of interest to see to what extent equation (1) is borne out by our experimental numbers.

The value that we have obtained for the lower limit of inflammation of methane when mixed with air is 5.6.* That is to say, the lower-limit mixture contains 5.6 per cent. by volume of methane. The calorific value of methane is 189.1.† Substituting in equation (1) we obtain a value for k of 1059, and the relative values for L for other gases can then be calculated.

In the table that follows the relative values of L are calculated from equation (1) in this manner, using methane as the standard to obtain the value of k . The observed values of L were obtained for the pure gases in the manner described in the experimental part of this paper. In every case the mixtures were ignited in a closed spherical vessel when at atmospheric pressure, and saturated with moisture at the room temperature (20—25°). The values are expressed as volumes of the inflammable gas per hundred volumes of mixture. In a separate column are given the lower calorific values of the gases at constant volume expressed in large calories per gram-molecule:

Gas.	Calorific value.	L observed.	L calculated.
Methane	189.1	5.60 standard	5.60
Ethane	336.6	3.10	3.15
Propane	484.2	2.17	2.19
n-Butane	631.7	1.65	1.68
n-Pentane	779.2	1.37	1.36
iso-Pentane	779.2	1.32	1.36

* Throughout this paper, unless otherwise stated, the numbers given for the lower limits of inflammation are expressed as percentages by volume of the mixture of the combustible gas with air, and refer to mixtures at atmospheric pressure and pressure.

† The value used in the lower value (Thomson) expressed in large calories per gram-molecule.

The agreement between the observed and calculated values of L is very striking, and seems to point to a definite and dominating relationship between the calorific values of the gases named in the table—the paraffin hydrocarbons—and their lower limits of inflammation when mixed with air.

If, however, it is attempted to calculate the lower limit for gases other than the paraffin hydrocarbons in the same way, using methane as the standard to obtain the value of k , the results do not all agree with experiment; thus, hydrogen, for which Le Chatelier gives an experimental value 10.0 ("Leçons sur le Carbone," p. 266), should have a value 18.45 according to equation (1). There is, therefore, some other factor to be considered.

This becomes apparent also on attempting to calculate the theoretical quantities of gas that are necessary to obtain a lower-limit mixture, assuming the reaction on ignition to take place adiabatically.

If T = the temperature of ignition of the mixture;

t = the initial temperature;

c' = the specific heat at constant volume of air;

c'' = the specific heat at constant volume of the combustible gas;

x = the amount of combustible gas present by weight;

$100 - x$ = the amount of air present by weight;

Q = the heat evolved by one part by weight of the combustible gas;

then:

$$[(100 - x)c' + xc''](T - t) = Qx,$$

or:

$$x = \frac{100c'(T - t)}{Q - (c'' - c')(T - t)}.$$

The value of $(c'' - c')(T - t)$ can be neglected compared with that of Q , being of the order of 1 part in 1000. So that, if $t = 0$, the equation becomes:

$$x = \frac{100c'T}{Q} \dots \dots \dots (2).$$

In attempting to use this equation for the calculation of the quantities of the paraffin hydrocarbons necessary, one is faced with the difficulty that their ignition-temperatures are very ill-defined, thus, Dixon and Coward (*loc. cit.*, p. 519) give the following figures for methane, ethane, and propane burning in oxygen:

Methane	between 556 and 700°
Ethane	520 " 630
Propane	490 " 570

and reference to the experimental part of their paper shows that in the case of all three gases peculiarities were noticed for which

no satisfactory explanation was offered. Their behaviour was, however, similar in many respects, and seemed to indicate an unduly prolonged period of slow, flameless combustion before ignition took place.

All things considered, the lower values seem to be the best to choose for the purpose of calculating the lower limits; for we wish to know the least amount of heat required.

For these three gases, the only members of the paraffin series of which Dixon and Coward have determined the ignition-temperatures, we have calculated the lower-limit values from equation (2), using the gram and the large calorie as units, and taking the specific heat of air at constant volume as 0.169.

Gas.	Percentage by weight required to form a lower-limit mixture.	Percentage by volume.	
		Calculated.	Observed.
Methane	0.795	1.426	5.60
Ethane	0.783	0.754	3.10
Propane	0.753	0.495	2.17

That the calculated values should be smaller than the observed is easily explained by the fact that the reaction that takes place on ignition has been assumed to be adiabatic, whereas actually heat is bound to be communicated from the gases first inflamed, not only to the adjacent layer, but to layers at a further distance. The amount of heat transmitted in this way must be determined chiefly by the speed at which the flame is propagated; for the more rapidly each successive layer is raised to its ignition-temperature the less will be the quantity of heat dissipated throughout more distant layers or through the walls of the containing vessel. Further than this, a certain proportion of the energy liberated during the reaction appears as radiant energy, and is not imparted to the products of combustion as sensible heat.

In the case of the three paraffin hydrocarbons, methane, ethane, and propane, the observed quantities required to form lower-limit mixtures with air are about four times the calculated quantities. In the case of hydrogen, however, the calculated quantity is 5.92, whilst the observed (Le Chatelier) is 10.0; that is to say, only about one and three-quarter times as great. The factors, therefore, other than the calorific value of the gas, which determine the quantity necessary to form a lower-limit mixture, operate in a different degree in the case of the paraffin hydrocarbons from what they do in the case of hydrogen or, no doubt, other inflammable gases.

From the fact that for all the paraffin hydrocarbons experimented with these factors taken together assume a constant value [as shown by the close agreement of equation (1) with experiment], it would appear that the mechanism of combustion of the inflammable gas

plays an all-important part in determining the quantity necessary to form a lower-limit mixture. For in the case of the paraffins the chemical changes resulting in inflammation are of a similar nature, the result of the initial encounter between the molecule of hydrocarbon and oxygen being, in each case, the formation of an oxygenated molecule; thus Bone and Wheeler (Trans., 1902, 81 536; 1903, 83, 1074) have shown that unstable intermediate products are formed during the slow combustion of methane, according to the following scheme of reaction:

Similarly, in the case of ethane, Bone and Stockings (Trans., 1905, 87, 1232) have shown that formaldehyde and acetaldehyde are formed as intermediate products during slow combustion (see also Bono and Drugman, Trans., 1906, 89, 660).

In our experiments we have found that whenever the mixture contained less of the particular paraffin hydrocarbon used than was required to enable self-propagation of flame to take place, the water contained in the spherical explosion vessel gave an aldehydic reaction with Schiff's reagent; but that after a lower-limit mixture had been ignited no aldehydes could be detected. In the latter case the heat of reaction destroyed the aldehydes as soon as formed; in the former, where the flame burned only in the vicinity of the electric spark, the intermediate products of combustion had time to diffuse away to the cool parts of the containing vessel.

This mode of combustion "by stages" of the paraffins is to our mind a sufficient explanation of the difficulty that Dixon and Coward experienced in fixing a definite ignition-temperature for methane, ethane, and propane*; and it suggests a reason why, since their behaviour on oxidation is similar, the calorific value of the paraffins is the sole determining factor in calculating the relative lower limits of inflammation of mixtures of each with air.

EXPERIMENTAL.

The method of experiment that we have adopted has been that of passing an electric spark from an induction coil between ter-

* Professor Dixon informs me that during the experiments made to obtain the ignition-temperatures of methane, ethane, and propane, a powerful odour of aldehyde was always noticed just before the gases inflamed, and that in some experiments the production of aldehyde seemed to be continued over a prolonged period at temperatures which in other experiments were sufficient to inflame the gases.

ninals placed at the centre of the mixture of inflammable gas and air contained in a spherical vessel of about 2 litres capacity.

Previous workers have generally used an eudiometer tube of the diameter usually employed in the explosion analysis of gases; and have ignited the mixture either by passing an electric spark between platinum electrodes fused into the glass at one end of the tube, or by holding a lighted candle or taper to an open end of the tube, the other end being closed. In either case the lower-limit mixture has been taken to be that in which the flame just travelled from one end of the tube to the other.

We considered that the cooling effect of the walls of such tubes may have influenced to some extent the results obtained, and therefore decided to use the spherical vessel above-mentioned, in

FIG. 1.

which the cooling by the walls would be reduced to a minimum. This method of experiment would also, it was thought, approximate more nearly to the conditions under which accidental ignitions of firedamp may take place in mines. We wished, moreover, to obtain some evidence of the influence, if any, of the size and intensity of the source of heat used to cause ignition, and of small variations in the initial temperature and pressure of the mixtures, on their lower-limit values.

The apparatus used is shown diagrammatically in Fig. 1. It consisted of a stout-walled glass globe nearly 16 cm. in diameter, with a capacity of just under 2 litres. The electrodes *A A*, which could reach to the centre, were platinum knobs, 3 mm. in diameter carried by stout platinum wires (coated with glass) along a diameter of the globe, passing by means of the parallel-ground joints, *B B*, through its walls. Each electrode, by reason of this

ground-glass connexion to the globe, could move horizontally through a distance of 3 cm., thereby allowing a maximum spark-gap of 6 cm. to be used. These "parallel" joints were made from accurately-ground hypodermic syringes, and, when lubricated with a solution of indiarubber in vaselin, maintained a vacuum during several hours.

Entrance to the globe was obtained through the tubulure *C*, to which was sealed a three-way tap of the form shown in the diagram. One branch of this tap made connexion with a glass gas-holder, in which the mixture to be experimented with was stored, and the other led to a mercury syphon manometer and a vacuum pump.

In all but a few special experiments a little distilled water (about 5 c.c.) was placed in the globe to saturate the mixture with water vapour at the room temperature.

Preparation of the Gas and Air Mixtures.—The mixtures were prepared by adding measured volumes of the pure combustible gases to air, free from carbon dioxide, contained in graduated gas-holders over concentrated sulphuric acid. The apparatus employed is shown in Fig. 2. The pure combustible gas, which was stored in large test-tubes over mercury, was transferred, by means of the mercury trough and syphon, *A*, to the measuring cylinder, *B*, which was accurately graduated, and a volume taken sufficient to give the percentage required when mixed with four litres of air contained in the gas-holder, *C*. After being allowed to remain twelve hours to diffuse, a sample of the mixture was withdrawn and an explosion analysis made, a little pure electrolytic gas being added to ensure a good explosion.

The pure gases were prepared by the following methods:

Methane.—By the modification of Gladstone and Tribe's method described by Bone and Wheeler (Trans., 1902, 81, 541). The gas was freed from traces of hydrogen by passage through "oxidised" palladium sponge heated to 98°, and by subsequent liquefaction by means of liquid air. The ratio *C/A* obtained in explosion analyses was exactly 2.0, showing that the gas was quite free from hydrogen.

Ethane.—By the action of water on zinc ethyl. The gas was purified by several liquefactions with liquid air to remove traces of propane. The ratio *C/A* on explosion was 1.25 for one sample and 1.26 for another. (The ratio for pure ethane is 1.25.)

Propane and n-Butane.—By the action of nascent hydrogen (from zinc dust and dilute sulphuric acid) on the corresponding alkyl iodide. The gases were liquefied by cooling with solid carbon dioxide dissolved in ether, and fractionally distilled, the middle fraction only being collected. The sample of propane prepared

in this manner gave in an explosion analysis a ratio $C/A = 0.99$; the sample of butane gave a ratio $= 0.87$. (The ratios for pure propane and butane are 1.00 and 0.875 respectively.)

n-Pentane and isoPentane.—The pure liquids were obtained from Kahlbaum, and a "stock" mixture of the vapour and air was

FIG. 2.

procured in each case by drawing dry air through the liquid contained in a wash-bottle maintained at 25° . In this manner mixtures containing high percentages of the hydrocarbon vapours were obtained; that of *n*-pentane and air containing 78.0 per cent. of *n*-pentane, and that of isoPentane and air containing 45.6 per cent. of isoPentane. The ratio C/A on explosion in the case of the

first-named was 0.81, and in the case of the second 0.80. (The ratio for pure pentane is 0.80.)

The pentane and air mixtures for the experiments were prepared from these stock mixtures by further dilution with air.

The manner of determining the lower-limit mixtures was that of "trial and error"; for example, a mixture of methane and air containing 6.1 per cent. of methane having been tried and found to propagate inflammation on the passage of an electric spark, a second mixture was prepared containing 5.9 per cent. of methane. This also propagated flame. The percentage of methane was therefore further reduced by 0.10 in a new mixture, and so on, until no mixtures were obtained, differing in their content of methane from 0.20 per cent., one of which enabled flame to be propagated, while the other did not. The lower-limit mixture was taken to be the one containing the mean percentage of methane contained in these two mixtures.

The lower-limit mixture could be distinguished with certainty from that just containing insufficient combustible gas; for on the momentary passage of the electric spark sufficed to promote the inflammation of all the gas contained in the globe in the former case, and on further sparking no signs of combustion could be observed. Whilst in the latter case, although the flame of the burning gas might appear to travel nearly through the whole of the mixture on the first passage of the spark, and some doubt might exist as to whether it had not, in fact, travelled throughout, causing the spark to pass a second time, a "cap" appeared above it, showing that the mixture still contained combustible gas, and this cap remained whilst passage of the spark was continued, growing gradually smaller in size, until all the gas had been burnt.

As a further check, samples of the residual gases were withdrawn from the globe after experiments with mixtures near the lower limit, and complete analyses made.

All the experiments were made in a darkened room, so as to enable the appearance of the flames to be readily observed.

Results of Experiments.—Before considering the influence of the size and nature of the source of heat used to cause ignition, or the effect of variations in the initial temperature and pressure of the mixtures, we will give the details of the experiments made with the different gases when these conditions were constant.

For these experiments a spark-gap of 13 mm. was employed, the spark being obtained from a large induction coil. The initial pressure of the mixtures was between 760 and 765 mm., and the temperature between 20° and 25°. The gases were saturated with water-vapour at this temperature.

Fig. 3

To face page 10.

Three, and sometimes four, experiments were made with the mixtures verging on the lower limit, the remainder being done in duplicate. The percentages of combustible gas recorded, determined by explosion analysis, are correct within 0.05; that is to say, for example, a mixture recorded as containing 4.30 per cent. methane contained between 4.27 and 4.32 per cent.

Methane.

H ₂ present. Per cent. of mixture.	Effect of momentarily passing spark.	Effect of passing spark a second time.
4.30	Small flame or "cap" above spark, about 3 cm. high	Size of cap slightly diminished
4.50	Flame about 6 cm. high above spark	Size of cap slightly diminished
4.65	Flame about 8 cm. high spreading sideways above spark	Size of cap diminished
4.85	Large flame spreading through about a quarter of the mixture	Size of cap greatly diminished
5.00 and 5.25	Large flame spreading through about half the mixture	Size of cap greatly diminished
5.50	Distinct propagation, below the spark, of a blue flame which con- tinued for a short time after the passage of the spark ceased	Small cap above spark about 1.5 cm. high. (A sample of the residual gases in the globe was found to contain about 3 per cent. of methane)
5.70	The flame travelled slowly through- out the mixture	No cap could be seen
5.80 and 5.90	The flame travelled throughout the mixture fairly quickly	No cap could be seen
6.10	The flame travelled rapidly through- out the mixture	No cap could be seen

The lower-limit mixture contains between 5.50 and 5.70 per cent. of methane.

Our results are in good agreement with those obtained by Coquillon and by Mallard and Le Chatelier, but are quite at variance with those obtained by Teclu. The effect of the spark on mixtures containing as much as 4.50 per cent. of methane makes it impossible for us to believe, as Teclu states, that mixtures containing 3.20 or 3.67 per cent. of methane can propagate flame under normal conditions as regards the initial temperature and pressure of the mixtures, and we conclude that either his method of analysis or his method of preparing the mixtures was faulty. In Fig. 3 are given diagrams representing the appearance of the flames in the different mixtures after the first passage of the electric spark, from which it will be seen that no doubt could exist regarding the inability to propagate flame of the mixtures containing a lower percentage of methane than 5.50. These diagrams show the appearance of the flame when it had attained its maximum dimensions.

The manner of movement of the flame in the 5.50 per cent. mixture suggested that if the gases were free to expand, ignition might possibly be propagated for a short distance. To test this a different form of containing vessel was used, consisting of a vertical glass tube 3.5 cm. in diameter and 180 cm. long. The lower end of this tube expanded into a spherical chamber 10 cm. in diameter in which platinum electrodes were fixed 20 mm. apart. The upper end of the tube could be closed by a ground-glass stopper.

The gaseous mixture, containing 5.50 per cent. of methane, was passed into the previously evacuated apparatus through a tap near the spherical end. An experiment was first made with the upper end of the tube closed by the glass stopper. On passing the electric spark, the flame of the burning gases filled the spherical chamber and extended about 10 cm. upwards in the vertical tube. A second experiment was then made with a fresh supply of the same mixture. In this experiment, just before the spark was passed, the glass stopper was removed, leaving the upper end of the tube open to the outside air. The flame extended about 30 cm. up the vertical tube, and then died out.

Altogether, we are satisfied that the figure we give, 5.60, represents the smallest possible percentage of methane in a methane and air mixture that can enable self-propagation of flame to take place when the initial temperature and pressure of the mixture are atmospheric.

Ethane.

C_2H_6 present, Per cent. of mixture.	Effect of momentarily passing spark.	Effect of passing spark a second time.
2.40	A small flame above the spark, about 3 cm. high	Size of cap slightly diminished
2.70	Flame about 5 cm. high above spark	Size of cap slightly diminished
2.90 and 2.95	Large flame spreading through about one-third of the mixture	Size of cap greatly diminished
3.00	The flame travelled slowly through nearly the whole of the mixture	Small cap above the spark
3.20	The flame travelled fairly quickly throughout the mixture	No cap could be seen
3.35	The flame travelled rapidly through- out the mixture	No cap could be seen
3.50	The movement of the flame through- out the mixture could just be followed with the eye	No cap could be seen

The lower-limit mixture contains between 3.00 and 3.20 per cent of ethane.

Propane.

C_3H_8 present. Per cent. of mixture.	Effect of momentarily passing spark.	Effect of passing spark a second time.
1.00	Small flame above spark about 6 cm. high	Size of cap diminished
1.10	Flame above spark spreading through about one-quarter of the mixture	Size of cap much diminished
1.15	Flame spreading nearly through the whole mixture	Small cap above spark
2.20	The flame spread slowly through the whole mixture	No cap could be seen
2.25	The flame moved fairly quickly through the mixture	No cap could be seen

The lower-limit mixture contains between 2.15 and 2.30 per cent. of propane.

n-Butane.

C_4H_{10} present. Per cent. of mixture.	Effect of momentarily passing spark.	Effect of passing spark a second time.
1.60	The flame reached the top of the globe and spread sideways through about one-third of the mixture	Small cap above spark
1.70	The flame travelled slowly through the whole mixture; its movement could easily be followed with the eye	No cap could be seen
1.80	The flame travelled fairly quickly through the whole mixture	No cap could be seen

The lower-limit mixture contains between 1.60 and 1.70 per cent. of *n*-butane.

n-Pentane.

C_5H_{12} present. Per cent. of mixture.	Effect of momentarily passing spark.	Effect of passing spark a second time.
1.25	Flame above spark about 6 cm. high	Size of cap diminished
1.30	Flame above spark spreading through about one-third of the mixture	Size of cap much diminished
1.35	Flame above spark spreading through about half the mixture	Size of cap greatly diminished
1.40	The flame travelled slowly through-out the mixture	No cap could be seen
1.45	The whole of the gas burned fairly quickly	No cap could be seen

The lower-limit mixture contains between 1.35 and 1.40 per cent. of *n*-pentane.

isoPentane.

C_5H_{12} present. Per cent. of mixture.	Effect of momentarily passing spark.	Effect of passing spark a second time.
0.90 and 1.20	Very small cap above spark	—
1.30	Flame above spark spreading through about one-third of the mixture	Small cap above spark
1.35	The flame travelled slowly through- out the mixture	No cap could be seen
1.40 and 1.45	The flame travelled fairly quickly throughout the mixture	No cap could be seen

The lower-limit mixture contains between 1.30 and 1.35 per cent of isopentane.

The Influence of the Size and Intensity of the Initial Source of Heat.—In discussing the influence of the volume of the initial source of heat on the propagation of flame in explosive mixtures of gases, Mallard and Le Chatelier put forward considerations (*loc. cit.*, p. 353), which can be paraphrased as follows: Assume that the source of heat is a sphere the temperature of which is higher than the ignition-temperature of the mixture. Before the molecules actually in contact with this sphere reach ignition-temperature, the surrounding molecules will have attained a certain temperature which will be lower the greater their distance from the heated sphere. The sphere, therefore, must communicate a certain quantity of heat to the surrounding gas before combustion can take place, without losing so much heat as to lower its temperature below the ignition-temperature of the mixture. The amount of heat communicated by the sphere in a given time is proportional to its radius squared (r^2), whilst the total quantity of heat that it contains is proportional to its radius cubed (r^3). It is obvious that the ratio between these two quantities, on which the propagation of inflammation depends, is proportional to the radius, that is to say, to the volume, of the sphere. This is found to be the case in actual experiment; a small electric spark of high temperature is insufficient to cause the inflammation of weak mixtures, which can, however, readily be ignited by the flame of a lamp—of less intensity than the electric spark, but of larger volume.

In the case of non-explosive mixtures, which contain a certain quantity of inflammable gas, but are unable to propagate flame, the introduction of a sphere the temperature of which is maintained above the ignition-temperature of the mixture will cause the combustion of the gas in a zone concentric with the sphere. The heat of combustion will increase the temperature of the surrounding mixture and automatically extend the radius of this zone. The sphere will thus be surrounded by a burning layer, the thickness

which will be greater the higher the temperature of the sphere and the nearer the mixture approaches the lower-limit mixture.

It would appear, therefore, that above a certain limit, no increase in the size and intensity of the source of heat can affect the percentage of combustible gas that must be present to form a lower-limit mixture. The only effect that can follow an increase in the magnitude of the source of heat introduced into a mixture containing less combustible gas than is required to form a lower-limit mixture is an increase in the size of the aureole surrounding it.

We have made a number of experiments with mixtures of methane and air and ethane and air, in which the length of the spark from the induction coil was either 10, 15, 30, or 50 mm. The longest spark was no more effective than the shortest, and no great difference could be observed in the height of the cap formed.

Finally, by employing a Wehnelt electrolytic interrupter in circuit with the primary of the induction coil, using a current of 110 volts, we obtained a "flaming" spark, 30 mm. long, of large volume and great intensity. Comparative experiments were made with this source of ignition with most of the mixtures enumerated in the preceding tables. The results were, in general, as have been anticipated. The percentage of combustible gas required to form a lower-limit mixture suffered no reduction in consequence of the more violent means of ignition, but the size of the aureole surrounding the spark was greatly increased. Moreover, with mixtures that were capable of propagating flame, the flame appeared to travel more rapidly, and a greater pressure was momentarily produced than when the ordinary spark was used to cause ignition.

In illustration of the increase of the size of the aureole, the case of a mixture of ethane and air containing 2.45 per cent. of ethane may be mentioned. With the ordinary spark from the induction coil a cap about 3.5 cm. high appeared above the spark; with the Wehnelt spark the flame of the burning gases reached to the top of the globe and spread outwards through about one-third of the mixture.

The increased rapidity of combustion of inflammable mixtures is well shown in the case of a mixture of ethane and air containing 3.5 per cent. of ethane. When ignited by the ordinary spark the gases burned rapidly, but the movement of the flame could be followed with the eye; ignited by means of the Wehnelt spark, the mixture exploded violently, shattering the globe.

It has been suggested to us that the reason for this increased rapidity of combustion may lie in the great ionising power of the Wehnelt spark, and that, possibly, ionisation from an external source and ignition by means of an ordinary spark might produce

similar effects to the combined ignition and ionisation of the Wehnelt spark. We hope to be able to test this point.

The Influence of Small Variations in the Initial Temperature and Pressure of the Mixtures.—The experiments that we have made on the influence of the initial temperature and pressure of the mixtures in determining their lower-limit values have been confined to such small variations as may occur in coal-mining practise. That is to say, the highest temperatures and pressures that we have employed have been but little more than can exist in the deepest mine at present worked.

Such small variations in temperature and pressure do not appear to have any measurable influence on the lower-limit value of methane and air mixtures. With the initial temperature as high as 35° , and the pressure 800 mm., no self-propagation of flame could be observed with mixtures containing less than 5.60 per cent. of methane. On the other hand, with mixtures of ethane and air there seemed to be a tendency for mixtures containing slightly less than 3.10 per cent. of ethane to propagate flame when the initial pressure of the mixture was greater than 780 mm. and the Wehnelt spark was used; thus, in two experiments a mixture containing 3.00 per cent. of ethane propagated flame, the initial temperature being 24° . In another mixture, containing 2.95 per cent. of ethane, the flame only travelled through about two-thirds of the mixture.

We hope to be able to extend this work to a more complete study of the effect of pressure on the lower limit.

We wish to express our thanks to the Mining Association of Great Britain for permission to publish these results; and to the Explosions in Mines Committee of the Home Office for ratifying that permission.

ALTOFTS.

CCXXIX.— β -2-Methoxynaphthylpropionic Acid and Methoxyperinaphth-hydrindone.

By GEORGE BARGER and WALTER WILLIAM STABLING.

A RECENT paper by Sachs and Brigl (*Ber.*, 1911, **44**, 2091) on ring-formation in the *peri*-position in the naphthalene series induces us to publish some experiments on the same subject which we made about a year ago, with but partial success. The method we wished to adopt was very similar to that which Sachs and Brigl had in view, namely, the removal of water from a naphthylacrylic or

propionic acid by a reaction like that used in the preparation of hydrindone. In order to prevent ring-formation by the removal of the hydrogen atom in position 2, we first replaced that hydrogen atom by a methoxy-group, and started therefore from 2-methoxy-naphthaldehyde. This was fairly readily converted into 2-methoxy-naphthylacrylic acid (I):

(I.)

(II.)

Sachs and Brigl, who employed the corresponding ethoxylaldehyde, were unable to bring about a similar condensation, and only obtained naphthacoumarin (II) by loss of the ethyl group. In our case this difficulty made itself felt in the next reaction (with phosphoric oxide), so that we likewise failed in our attempt to form a perinaphthindenone. When the naphthylacrylic acid was heated with excess of phosphoric oxide in benzene solution, no product could be isolated except a little of the naphthacoumarin (II), and this substance was also formed, in much larger quantity, when we heated the acrylic acid with one molecular proportion of phosphorus pentachloride. On the other hand, when we had reduced the naphthylacrylic acid to the corresponding propionic acid, its behaviour towards phosphoric oxide was changed, and we obtained a small quantity of a substance which we consider to be a perinaphth-hydrindone of the constitution III:

(III.)

The yields of methoxynaphthylpropionic acid and also of the above substance were so small that we were unable to prepare the corresponding phenol in order to submit it to distillation with zinc dust, as we had hoped to do.

EXPERIMENTAL.

Methylation of 2-Hydroxynaphthaldehyde.

Commercial hydroxynaphthaldehyde (from Schuchardt) and methyl sulphate were used. To 50 grams of the aldehyde, dissolved

in 440 c.c. of methyl alcohol, were added 28.6 c.c. of methyl sulphate, and then 27.4 c.c. of aqueous potassium hydroxide (11*N*). The addition of methyl sulphate and of potassium hydroxide was repeated twice. Each time a vigorous reaction should take place, and large quantities give a better yield than smaller ones. In the above experiment 43 grams of ether were obtained, and 10 grams of the hydroxyaldehyde were recovered. These were again methylated, so that the final yield amounted to 95 per cent. of the theory.

2-Methoxynaphthaldehyde is best purified by distillation; it boils at 205°/18 mm., and melts at 84°.

β -2-Methoxynaphthylacrylic Acid, $\text{CH}_3\text{O}\cdot\text{C}_{10}\text{H}_7\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$.

The above aldehyde did not react with sodium acetate and acetic anhydride, but it did with ethyl acetate and sodium. Ten grams of the aldehyde dissolved in 9.5 grams of ethyl acetate were treated with 1.25 grams of finely divided sodium (prepared by shaking under hot toluene). The resulting ester was hydrolysed on the water-bath with methyl-alcoholic sodium hydroxide, and yielded 11 grams of the crude acid, which separated from benzene and light petroleum in very pale yellow needles, melting at 160°:

0.1580 gave 0.4261 CO_2 and 0.0765 H_2O . $\text{C}=73.55$; $\text{H}=5.4$.

0.1286 was neutralised by 5.6 c.c. $N/10\text{-NaOH}$. $\text{M.W.}=229$.

$\text{C}_{14}\text{H}_{12}\text{O}_3$ requires $\text{C}=73.7$; $\text{H}=5.3$ per cent.; $\text{M.W.}=228$.

When the acid was heated on the water-bath in benzene solution with phosphoric oxide we could only isolate a minute quantity of a yellow, crystalline, neutral substance, which could not be purified completely, but was probably naphthacoumarin, first prepared by Kaufmann (*Ber.*, 1883, 16, 686). The melting point was very indefinite, at about 80°, instead of 118°. By heating the same acid with one molecular proportion of phosphorus pentachloride on the water-bath, and distilling under diminished pressure, we obtained a 65 per cent. yield of a yellow substance, boiling at about 240°/12 mm. After crystallisation from benzene and light petroleum it melted at 117°, and was further identified with naphthacoumarin by analysis (Found, $\text{C}=79.8$; $\text{H}=4.2$. Calc., $\text{C}=79.6$; $\text{H}=4.1$ per cent.), and by the green fluorescence of its solution in concentrated sulphuric acid.

It is clear, therefore, that the methyl group was eliminated in the same way as the ethyl group in the experiments of Sachs and Brigl. The saturated acid, however, was found to react somewhat differently with phosphoric oxide, and in this case we obtained the desired *perinaphth-hydrindone*.

β -2-Methoxynaphthylpropionic Acid, $\text{CH}_3\cdot\text{O}\cdot\text{C}_{10}\text{H}_7\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$.

The crude methoxynaphthylacrylic acid obtained from 20 grams of the aldehyde was reduced in sodium carbonate solution by 1 kilo. of 3 per cent. sodium amalgam, the solution being stirred by a motor. The mixture of acids which resulted was precipitated by hydrochloric acid, and extracted with several litres of boiling water, from which the saturated acid separated on cooling in colourless needles, melting at 128° . Yield, 2.6 grams:

0.2596 gave 0.6981 CO_2 and 0.1439 H_2O . $\text{C}=73.3$; $\text{H}=6.1$.
 0.1500 was neutralised by 6.45 c.c. $\text{N}/10\text{-KOH}$. $\text{M.W.}=232$.

$\text{C}_{11}\text{H}_{14}\text{O}_2$ requires $\text{C}=73.0$; $\text{H}=6.1$ per cent.; $\text{M.W.}=230$.

The acid did not reduce potassium permanganate. It dissolved in about 1000 parts of boiling water.

Methoxyperinaphth-hydrindone, $\text{C}_{14}\text{H}_{12}\text{O}_2$.

With the small quantity of the last-named acid at our disposal we could only carry out a few experiments with phosphoric oxide. The most successful one was as follows: 1.3 grams of the acid were dissolved in 10 c.c. of benzene, and heated on the water-bath with 6.7 grams of phosphoric oxide for two to three hours. Powdered ice was then added to the reddish-violet reaction product, and after extraction with ether and washing with sodium carbonate, we obtained a small quantity of a yellow substance, which was distilled at $210^\circ/12$ mm., and then crystallised from benzene and light petroleum in deep yellow prisms, melting at 135° :

0.1314 gave 0.3897 CO_2 and 0.0583 H_2O . $\text{C}=79.1$; $\text{H}=4.8$.
 $\text{C}_{14}\text{H}_{12}\text{O}_2$ requires $\text{C}=79.2$; $\text{H}=5.6$.

$\text{C}_{14}\text{H}_{10}\text{O}_2$ " $\text{C}=80.0$; $\text{H}=4.8$ per cent.

Of these two formulæ the first is by far the most likely. We satisfied ourselves that the methoxy-group was still intact, for on boiling with hydriodic acid, methyl iodide was evolved, but we had not enough material to repeat the analysis. We hope to find a better method of reducing methoxynaphthylacrylic acid in order to continue the experiments.

CHEMICAL LABORATORY, GOLDSMITHS' COLLEGE,
 NEW CROSS, LONDON, S. E.

CCXXX.—*Syntheses with Phenol Derivatives Containing a Mobile Nitro-group. Part V. Quinoxalines, Asymmetric Quaternary Ammonium Compounds, and Asymmetric Carbinols (continued).*

By RAPHAEL MELDOLA and HAROLD KUNTZEN.

THE main object of the present extension of the research has been the study of the influence of the radicles X, Y, and Z in iminazolum compounds of the type:

on the general properties of these compounds, with a view to the selection of the most suitable types for the proposed investigation of the optical properties in the event of the bases or carbinols being resolvable. It was pointed out in our last paper (this vol., p. 1283) that the radicles in question were completely under control, and in the cases hitherto studied X has stood for phenyl and *p*-tolyl, and Z, excepting in one case, for methyl. In the present paper we describe other sets of compounds, in which X is represented by *p*-chlorophenyl, *p*-anisyl, and benzyl, Y and Z standing for methyl. Special attention has also been paid to the radicle Y attached to the 2-carbon atom, with a view to obtaining a series of homologues, and we have succeeded in preparing the compounds in which Y is represented by ethyl and isobutyl respectively, Z standing throughout this series for methyl, and X for phenyl. It is evident that there is scope for the indefinite extension of the research in the direction of synthesising new iminazoles and carbinols, but the fertility of the method has been sufficiently proved by the cases studied in this and the former papers, and it will be unnecessary to multiply instances, except for the elucidation of special points of theoretical interest. The general outcome of the experiments up to this point is to show that when the radicle X contains an acid substituent (Cl), the ammonium base forms salts of greater stability than when no such substituent is present. It appears also that with increase of weight in Y the general internal mobility also increases, so that in the higher homologues the conversion of the carbinol into the ammonium base takes place with extreme facility, a fact which

may be taken as proving that in this series the presence of hydroxyl in the benzene ring so influences the character of the molecule as to render the quinoneimide form the more stable. In this connexion it is of interest to recall the observations of Japp and Moir (*Trans.* 1900, **77**, 608), which indicate that in the case of the derivatives of lophine the carhinol form is the more stable, since the ammonium form passes readily into the latter.*

Further Theoretical Considerations.

The extension of the work since our last communication has led incidentally to the reconsideration of the theoretical interpretation of our results, and certain questions of considerable importance in relation to the formulæ proposed have necessarily arisen. As the result of our later work we see no reason for modifying the views advanced in our last paper, although there are certain assumptions upon which these views rest which require further verification. We propose calling attention to some of these points now, as much evidence will have to be accumulated before the questions raised can be satisfactorily settled. The question as to which of the two forms is the carhinol has already been dealt with (this vol., p. 1285). The evidence, as far as it goes, seems fairly conclusive, although the basic character of the isomeric iminazolium compound as evidence of the constitution of that form is to some extent weakened by the circumstance that the carbinols obtained by Otto Fischer are also basic (*J. pr. Chem.*, 1906, [ii], **73**, 422). It does not appear, however, from the researches of this author that the carbinols containing acid substituents in the benzene ring are likewise basic.

The argument from colour, although, as already pointed out (*loc. cit.*, p. 1286), subject to limitations, is, as far as it goes, in favour of the "quinoneimide" structure of the highly-coloured red form. The formula suggested for this modification on the strength of the evidence from colour, together with the chemical evidence already submitted, confessedly raises a difficulty which has led to the consideration of other possible formulæ for these coloured compounds. The formula in question (I) represents the quinonoid character, the relationship to the ammonium base, and the basic property of the molecule (see the general scheme in the last paper, *loc. cit.*, p. 1287), all of which characters are possessed by these red compounds. On the other hand, the alternative quinonoid formula (II) necessitates the assumption that a quinquivalent nitrogen atom

* The work of these authors furnishes a good example of the opening out of the iminazole ring, the ammonium hydroxide form of an amarine derivative passing spontaneously into the ethylenediamine derivatives.

can be in direct combination with carbon only, a state of combination hitherto unknown among quinquivalent nitrogen compounds. In answer to this objection it might be urged that the compound,

are capable of existing in form I only, and not in the tautomeric form II. In other words, they may be regarded as derivatives of the hypothetical dinitroaminoquinoneimide (III), and not of its tautomeride (IV):

Formula I represents the compound as the inner anhydride of the ammonium hydroxide derivative, and is in harmony with the fact that in some cases the transformation has been followed quantitatively by determining the actual loss of water on drying.* This formula does not violate any of the recognised canons of the constitution of the quinquivalent nitrogen compounds, as the fifth nitrogen bond is combined with the substituted acid phenyl nucleus. By this discussion there is thus raised the question of the possible existence of fixed quinonoid constitution, that is, of quinonoid compounds incapable of assuming the tautomeric (Fittig) form.

With respect to the possibility of quinquivalent nitrogen having all its bonds attached to carbon, it may be pointed out that groupings of the type $\text{C}=\text{N}=\text{C}$, in which both carbon atoms are contained in ring systems, have not hitherto been obtained so far as we are aware, so that no evidence from analogy appears to be available. In our compounds it will be noticed that one of the carbon atoms belongs to a ring highly charged with negative substituents, and may therefore be regarded as belonging to an acid

* It is only right to point out that in the majority of cases hitherto studied the ammonium hydroxide form could not be isolated, as it loses water readily, even on exposure to the air at the ordinary temperature, and passes into the anhydro-form. The extreme stability of these compounds when heated with concentrated sulphuric acid to the fuming point (this vol., p. 1294) is connected with the fact that it is the imine-zolium sulphate which is being dealt with under these conditions.

radicle. From this point of view the proposed formula falls into line with compounds of the oxy-trialkylamine type.

Of other possible formulæ, that which represents the coloured compounds as having an ortho-quinonoid structure has received much consideration. The researches which have been carried out by Hantzsch and his colleagues during the few past years have made us familiar with the existence of the *isonitro*-group (NO_2H) in compounds which had formerly been regarded as true nitro-derivatives, and reasons have already been given for suspecting such tautomerism in the original trinitroacetylaminophenol from which our iminazoles are prepared (Trans., 1910, 97, 453). It is, in fact, possible, although we have no direct evidence to adduce in support of such a view, that the iminazoles themselves may be susceptible of such tautomerism:

In this connexion it is perhaps worth recalling attention to the fact that all our iminazoles are in the solid state or in solution of a pale ochreous colour, while their alkaline solutions and their solid salts are of an orange colour. Assuming, therefore, in accordance with the generally accepted view (Pinnow and Sämann, *Ber.*, 1899, 32, 2181; Japp and Moir, Trans., 1900, 77, 614) that when in a ring system an atom of nitrogen becomes quinquevalent, it is preferentially that atom which is associated with the double linking, the methiodide and corresponding ammonium base might be formulated on the above hypothesis as quinonoid compounds (I), anhydridisation taking place with rearrangement of internal linking between the 3-hydroxyl group and the 7-*isonitro*-group. The product would then be an "inner" salt of the nitroic acid type, and would have an ortho-quinonoid structure (II):

This hypothesis is certainly worthy of being kept in view, although the balance of evidence seems to us to be against it. Some

of the objections to the proposed alternative scheme are worthy of record in view of their being met by further experimental evidence. In the first place, anhydridisation between hydroxyl groups in the meta-position is less probable than between such groups in the para-position, as is assumed in our original hypothesis. In the next place the formation of salts (iodides) by combining the quinonoid compounds (II) with acids would lead to the production of compounds isomeric with the original methiodide (III), unless we assume that there is another rearrangement of internal linking and the reconversion of the 3*N*-atom into the quinquivalent form. This is, of course, a possibility, but it introduces unnecessary complication into the chemical mechanism, and, as a fact, no such isomerism has hitherto been observed, the iodide obtained by combining the quinoneimide with hydriodic acid being apparently identical with the methiodide obtained by direct methylation of the iminazole (this vol., p. 1296).

The objection to the supposition that anhydridisation can take place between hydroxyl groups in the meta-position might perhaps be met by assuming that the hydrolysis of the methiodide results in the opening out of the iminazole ring with the formation of an intermediate ortho-diamine derivative, which, on this supposition, would be an inner salt of the nitroic acid type (I):

The latter might then be supposed to anhydridise in the usual way with the formation of the ortho-quinonoid compound (II). This view, which, as we learn from a private communication, has also suggested itself to Dr. James Moir, is, however, at variance with the experimental evidence. In no case have we observed any tendency for the iminazole ring to break down in our compounds, and experiments directed specially towards this end have, as shown in our last paper, thus far led to negative results. If the iminazole ring in these compounds were so easily broken down, they might be expected, in accordance with Otto Fischer's results, to furnish nitrosoamines by the action of nitrous acid, azines by oxidation, and ortho-diamine derivatives by complete hydrolysis. No one of these properties is possessed by our compounds. A crucial test of the validity of the ortho-quinonoid formula would be the formation of analogous compounds containing some substituent other

than a nitro-group in position 7. Experiments having for their object the synthesis of iminazoles containing a halogen atom in this position have been commenced, but we have not yet succeeded in preparing compounds of this type; this branch of the work has, however, only been tentatively dealt with at present.

So far as concerns the formation of the carbinol from the ammonium compound, either the ortho- or the para-quinonoid formula will represent the transformation. The balance of evidence is, however, thus far so distinctly in favour of the latter that we see no reason for departing from our original view of the constitution of these compounds.

EXPERIMENTAL.

In order to condense the descriptive details of the work as much as possible, each set of compounds is dealt with under the heading indicating the iminazole used as the starting point. In all cases the methiodide was first prepared.

The Iminazole from Trinitroacetylaminophenol and p-Anisidine.

The iminazole (Meldola and Hay, Trans., 1908, **93**, 1675) was converted into the iminazolium iodide by heating with excess of methyl iodide for three hours at 125°. The iodide, which consists of small, ochreous needles, is slowly decomposed by boiling with water, but more rapidly by boiling with dilute hydrochloric acid. On neutralising the hot acid solution with ammonia, the iminazolium compound separates out on cooling as a brick-red, micro-crystalline powder. The air-dried substance proved on analysis to be the quinoneimide, 4:7-dinitro-1-p-anisyl-2:3-dimethyl-6-benziminazolonone, a fact indicating that anhydridisation takes place very readily in this case, possibly in the hot aqueous solution:

0.0986 gave 13.7 c.c. N₂ (moist) at 21.5° and 759.9 mm. N=15.77.

$C_{18}H_{14}O_6N_4$ requires N=15.66 per cent.

The substance is extremely basic, dissolving readily in dilute acids with the formation of salts which are stable only in presence of excess of acid. The hydrochloride (4:7-dinitro-6-hydroxy-1-p-anisyl-2:3-dimethylbenziminazolium chloride) was prepared by the action of a saturated alcoholic solution of hydrogen chloride on the foregoing compound. It consists of small, white needles, easily dissociable by water:

0.0968 gave 0.0351 AgCl. Cl=8.96.

0.0858 „ 10.5 c.c. N₂ (moist) at 21.5° and 763 mm. N=13.95.

$C_{16}H_{15}O_6N_4Cl$ requires Cl=8.98; N=14.2 per cent.

The carbinol, 4:7-dinitro-6-hydroxy-1-p-anisyl-2:3-dimethyl-2-benziminazolol, was prepared by dissolving the iminazolone in warm dilute sodium hydroxide, and precipitating by hydrochloric acid. The compound separates as a microcrystalline, ochraceous powder, which passes readily into the red iminazolone on heating the conversion taking place in a few minutes on boiling with alcohol or water, and also slowly on drying the solid at 100°. The best analytical results were for this reason given by the air-dried substance:

0.1016 gave 13.2 c.c. N_2 (moist) at 19° and 771.5 mm. $N = 15.17$,
 $C_{16}H_{16}O_2N_4$ requires $N = 14.89$ per cent.

The Iminazole from Trinitroacetylaminophenyl and p-Chloroaniline

The iminazole (m. p. 246°; Meldola and Hay, Trans., 1908, 93, 1676) had to be heated with excess of methyl iodide to 130° for two to three hours to bring about complete transformation into the methiodide. The latter is a crystalline substance, consisting of dark ochreous scales. Decomposition was effected by boiling with dilute hydrochloric acid, the iminazolone being precipitated from the acid solution on adding ammonia in slight excess. This compound crystallises in small, ochreous scales, which do not decompose at 300°. An air-dried specimen was used for analysis:

0.0832 gave 11.5 c.c. N_2 (moist) at 20° and 759.5 mm. $N = 15.8$
 0.1088 „ 0.0420 AgCl. $Cl = 9.54$.

$C_{13}H_{11}O_3N_4Cl$ requires $N = 15.45$; $Cl = 9.77$ per cent.

This compound (4:7-dinitro-1-p-chlorophenyl-2:3-dimethyl-6-benziminazolone) is characterised by the stability of its hydrochloride, which is not completely dissociated by excess of hot water. It is for this reason that excess of ammonia is required for the precipitation of the pure iminazolone from its acid solution. The salt (4:7-dinitro-6-hydroxy-1-p-chlorophenyl-2:3-dimethylbenziminazolium chloride) was prepared by dissolving the iminazolone in 50 per cent. hydrochloric acid, filtering, and allowing to cool, when the compound separated as a white, microcrystalline powder, which was collected, washed with a little cold water, and allowed to dry in the air:

0.2012 gave 24.4 c.c. N_2 (moist) at 17° and 761.5 mm. $N = 14.16$,
 0.1627 „ (on decomposition by an alcoholic solution of silver nitrate) 0.0572 AgCl. $Cl = 8.70$.

$C_{13}H_{12}O_3N_4Cl_2$ requires $N = 14.04$; Cl (1 atom) = 8.88 per cent.

The carbinol, 4:7-dinitro-6-hydroxy-1-p-chlorophenyl-2:3-dimethyl-2-benziminazolol, was prepared in the usual way by dissolving the iminazolone in alkali, and precipitating by acid. It consists of an

ochreous, non-basic, microcrystalline powder, which is converted into the basic iminazolone on boiling with alcohol or water:

0.0976 gave 12.8 c.c. N_2 (moist) at 21° and 760.1 mm. $N=14.93$.
 $C_{13}H_{13}O_6N_4Cl$ requires $N=14.72$ per cent.

It will be noted that in this case, as in that of the *p*-tolyl compound (this vol., p. 1286), the iminazolone and carbinol do not differ markedly in colour.

The Iminazole from Trinitropropionylaminophenol and Aniline.

After numerous experiments having for their object the preparation of iminazoles having radicles other than methyl attached to the 2-carbon atom, it was found that the most satisfactory results were obtained by acylating the trinitroaminophenol prepared by the hydrolysis of its acetyl derivative (Meldola and Hay, *Trans.*, 1909, 95, 1378). For the present series the dry trinitroaminophenol was heated for some time on the water-bath with excess of propionic anhydride, the product diluted with water, and the solid propionyl compound purified by crystallisation from glacial acetic acid.

2:3:5-Trinitro-4-propionylaminophenol crystallises from acetic acid in nodular aggregates of opaque, ochreous needles, melting at $173-179^\circ$:

0.0915 gave 15.1 c.c. N_2 (moist) at 21.5° and 760.7 mm. $N=18.76$.
 $C_9H_8O_8N_4$ requires $N=18.67$ per cent.

4:7-Dinitro-6-hydroxy-1-phenyl-2-ethylbenziminazole was prepared from the above trinitro-compound by boiling it in alcoholic solution with aniline according to the method described in former papers. The product after crystallisation from alcohol with the addition of animal charcoal was obtained in ochreous, transparent, rhombohedral plates, becoming opaque at 100° , and melting at 173° :

0.1666 gave 24.5 c.c. N_2 (moist) at 17.5° and 760.7 mm.
 $N=17.04$.

$C_{15}H_{12}O_5N_4$ requires $N=17.08$ per cent.

4:7-Dinitro-6-hydroxy-1-phenyl-2-ethyl-3-methylbenziminazolium iodide was prepared by heating the iminazole with excess of methyl iodide to 120° for three hours. The product consisted of small, reddish-brown scales, the analysis of which indicated that the formation of the methiodide was practically complete:

0.1814 gave 18.3 c.c. N_2 (moist) at 18.7° and 755.7 mm. $N=11.54$.
 $C_{16}H_{15}O_5N_4I$ requires $N=11.92$ per cent.

4:7-Dinitro-1-phenyl-3-methyl-2-ethyl-6-benziminazolone was obtained from the iminazolium iodide by boiling the latter with dilute hydrochloric acid, and neutralising the filtrate with ammonia. After

being twice treated in this way, the pure compound was obtained in small, brick-red scales, decomposing above 300°:

0.0978 gave 13.9 c.c. N_2 (moist) at 21.5° and 774.4 mm. $N=16.4$.

$C_{15}H_{14}O_5N_4$ requires $N=16.47$ per cent.

4:7-Dinitro-6-hydroxy-1-phenyl-2-ethyl-3-methylbenziminazolinium chloride was prepared from the iminazolone by treating the latter in the cold with an alcoholic solution of hydrogen chloride. It crystallises in white granules, easily dissociable by water:

0.1500 gave 19.3 c.c. N_2 (moist) at 23° and 772 mm. $N=14.66$.

0.2258 " 0.0829 AgCl. $Cl=9.08$.

$C_{16}H_{15}O_5N_4Cl$ requires $N=14.8$; $Cl=9.36$ per cent.

The carbinol, 4:7-dinitro-6-hydroxy-1-phenyl-3-methyl-2-ethyl-2-benziminazolol, was prepared in the usual way by the action of dilute sodium hydroxide on the iminazolone, and precipitation by acid. It crystallises in microscopic, ochreous needles, which pass very readily into the red iminazolone on boiling with water or alcohol or on heating in the dry state:

0.0833 gave 0.1632 CO_2 and 0.0326 H_2O . $C=53.43$; $H=4.35$.

0.0786 " 11.1 c.c. N_2 (moist) at 25° and 764.6 mm. $N=15.55$.

$C_{16}H_{16}O_6N_4$ requires $C=53.3$; $H=4.48$; $N=15.55$ per cent.

The Iminazole from Trinitroisovalerylaminophenol and Aniline.

Attempts to prepare trinitroisovalerylaminophenyl by first introducing one or two valeryl groups into *p*-aminophenol and then nitrating the product under various conditions, showed that this method was unsatisfactory. The divaleryl compound is easily prepared by the action of valeric anhydride on *p*-aminophenol in the presence of a few drops of sulphuric acid, but the product is viscous and uncrystallisable. It can be nitrated in cooled glacial acetic acid by means of fuming nitric acid, and yields a dinitro-derivative, which crystallises in flat, ochreous needles, melting at 177°. The *O*-valeryl group is eliminated during nitration as the product is phenolic, and has the composition of a dinitromono-valeryl-*p*-aminophenol:

0.1186 gave 15.05 c.c. N_2 (moist) at 14° and 768.2 mm. $N=15.09$.

$C_{11}H_{13}O_6N_3$ requires $N=14.84$ per cent.

This dinitro-compound could not be readily converted into a trinitro-compound, so the method was abandoned, and the alternative process of acylating trinitroaminophenol adopted.

2:3:5-Trinitro-1:4-diisovalerylaminophenol was prepared by the action of excess of isovaleric anhydride on *p*-aminophenol. In the presence of sulphuric acid acylation takes place readily at the

dinary temperature in the course of a few hours; without sulphuric acid acylation takes place readily on warming on the water-bath for about an hour. In both cases the divaleryl compound is produced, the latter crystallising from alcohol in pale yellow needles, melting at 119°.

0.0770 gave 9 c.c. N_2 (moist) at 16° and 762.7 mm. $N=13.68$.

$C_{14}H_{15}O_5N_4$ requires $N=13.59$ per cent.

4:7-Dinitro-6-hydroxy-1-phenyl-2-isobutylbenziminazole was prepared by heating the foregoing compound with excess of aniline in alcoholic solution in the usual way. After purification by alkaline treatment and crystallisation from alcohol, it consists of ochreous crystals, melting at 156°.

0.1712 gave 0.3602 CO_2 and 0.0778 H_2O . $C=57.39$; $H=5.04$.
0.1330 „ 18.2 c.c. N_2 (moist) at 20° and 759.4 mm. $N=15.63$.

$C_{17}H_{16}O_5N_4$ requires $C=57.27$; $H=4.52$; $N=15.73$ per cent.

It is of interest to note that during the formation of this iminazole, the *O*-isovaleryl group is eliminated, and that isovaleramide is found among the products left after the process of purification by alkaline extraction.

4:7-Dinitro-6-hydroxy-1-phenyl-2-isobutyl-3-methylbenziminazolium iodide was prepared by heating the iminazole in a sealed tube with excess of methyl iodide for three hours at 120°. The methylation appeared to be very complete, the methiodide crystallising in orange-red needles. Decomposition of the methiodide was readily effected by boiling the crystalline compound with dilute hydrochloric acid, in which it freely dissolves, filtering the solution, and neutralising with ammonia, when the iminazolium base is precipitated as an orange, microcrystalline powder. In order to ensure complete decomposition of the methiodide, the treatment with dilute hydrochloric acid was repeated.

4:7-Dinitro-1-phenyl-3-methyl-2-isobutyl-6-benziminazolone is a substance of distinctly basic character, dissolving readily in all mineral acids, and being precipitated unchanged on neutralising the acid solution with ammonia. The decomposing point is above 300°. The compound may exist in the ammonium hydroxide form when freshly precipitated, but it loses water on drying in the air at the ordinary temperature, and passes into the quinoneimide:

0.1148 gave 15.5 c.c. N_2 (moist) at 22° and 772.6 mm. $N=15.55$.

$C_{18}H_{18}O_5N_4$ requires $N=15.13$ per cent.

The iminazolium chloride is formed from the quinoneimide by the action of an alcoholic solution of hydrogen chloride, from which solvent it separates in small, white needles, readily dissociable by water with the regeneration of the quinoneimide:

0.1286, decomposed in alcoholic solution with silver nitrate, gave 0.0455 AgCl. Cl=8.74.

$C_{13}H_{19}O_5N_4Cl$ requires Cl=8.71 per cent.

The carbinol, 4:7-dinitro-6-hydroxy-1-phenyl-3-methyl-2-isobutyl-2-benziminazolinol, was prepared in the usual way by dissolving the quinoneimide in warm dilute sodium hydroxide, and precipitating by hydrochloric acid. It crystallises in small, ochreous needles, which pass with extreme readiness into the ammonium form, a few minutes' boiling with water or alcohol being sufficient to convert the phenolic carbinol into the basic ammonium compound. The specimen used for analysis was dried in the air at the ordinary temperature, as heating in the water-oven brings about partial dehydration owing to the formation of the quinoneimide:

0.1263 gave 16.3 c.c. N_2 (moist) at 22.5° and 757.2 mm. N=14.52.

0.1182 „ 0.2404 CO_2 and 0.0522 H_2O . C=55.47; H=4.91.

$C_{18}H_{26}O_6N_4$ requires C=55.64; H=5.19; N=14.43 per cent.

The Iminazole from Trinitroacetylaminophenol and Benzylamine.

The iminazole (Trans., 1906, 89, 1940) was methylated by heating with excess of methyl iodide for two hours at 120° . The methiodide consisted of red, ochreous scales, which required prolonged boiling with water in order to effect conversion into the iminazolium compound, the latter crystallising from the solution on cooling in bright red needles, melting and decomposing at $252-253^\circ$. Analyses of the air-dried substance showed that dehydration had taken place with the formation of the iminazolone, 4:7-dinitro-1-benzyl-2:3-dimethyl-6-benziminazolone:

0.0638 gave 8.9 c.c. N_2 (moist) at 12.5° and 751.3 mm. N=16.33.

$C_{16}H_{14}O_5N_4$ requires N=16.37 per cent.

The iminazolium chloride was prepared by dissolving the iminazolone in alcoholic hydrochloric acid and adding ether; the salt separates as a pale, ochreous, microcrystalline powder, having when dry a melting point of 218° :

0.0638 gave 8.1 c.c. N_2 (moist) at 14° and 764.5 mm. N=15.02.

0.1328 „ (by the method of Carius) 0.0501 AgCl. Cl=9.32.

$C_{16}H_{18}O_5N_4Cl$ requires N=14.8; Cl=9.36 per cent.

The salt used for analysis was air-dried, as it dissociates on heating, and also rapidly in contact with water, the red iminazolone being regenerated. We have been unable to prepare the carbinol form of this compound owing to the extreme difficulty of realising the precise conditions necessary in order to ensure successful conversion of the iminazole into the iminazolium iodide. Numerous

experiments have been made under various conditions, but the results have so far been unsatisfactory. As the completion of this series is not of immediate importance, this part of the research has for the present been abandoned.

We desire, in concluding, to express our indebtedness to the Government Grant Fund of the Royal Society for material assistance towards the expenses of the research. We have also much pleasure in acknowledging the valuable co-operation of Mr. William F. Hottel, who has taken a considerable part in the experimental work. We may point out also that while the foregoing results were being prepared for publication, another research being carried out in our laboratory has led to the unexpected discovery of independent confirmation of the existence of quinoneimidium compounds of the type:

in which quinquevalent nitrogen is combined with three alkyl groups and a carbon atom belonging to the strongly acid quinonoid radical $[\text{C}_6\text{H}_2(\text{NO}_2)_2\text{O}]^{\text{III}}$ or IV , and therefore ascribable to the type of the oxytrialkyl or mixed ammonium compounds, O:N(Alk)_3 , $\text{O:N(Alk)}_2\text{Ar}$, etc. This discovery has arisen from the further study of the product of the extreme methylation of *isopieramic* acid described in a preliminary note by one of the authors published last year (*Proc.*, 1910, 26, 232). This research is in progress, and the results will be communicated to the Society when sufficiently mature.

CITY AND GUILDS OF LONDON TECHNICAL COLLEGE,
FINSBURY.

CCXXXI.—*The Synthesis of Derivatives of Thioxanthone. Part IV. Synthesis from Aromatic Sulphinic Acids.*

By HAROLD CHRISTOPHER and SAMUEL SMILES.

IN previous communications it has been shown that various types of thioxanthone derivatives may be synthesised from aromatic mercaptans (Trans., 1910, **97**, 1290), from aromatic disulphides (this vol., p. 1353), and from the products obtained by the union of a quinone with *o*-thiolbenzoic acid (this vol., p. 1535). In the two former methods the union of the thio-derivative with the aromatic compound is effected by the condensation of a sulphylic acid which is formed at an intermediate stage in the process, water being eliminated from this substance and the second aromatic nucleus. Since it has been formerly observed (Smiles and Le Rossignol, Trans., 1906, **89**, 700) that aromatic sulphinic acids readily condense with suitable aromatic compounds in the presence of sulphuric acid:

the present experiments were undertaken in order to apply this type of interaction to the production of thioxanthenes.

Both Gräbe (*Annalen*, 1891, **263**, 1) and Mayer (*Ber.*, 1909, **42**, 1134, 3046) have shown how easily thioxanthenes are formed by elimination of water from the *o*-carboxylic derivatives of substituted diphenyl sulphides:

so that the synthesis of thioxanthenes by this method is merely a question of choosing suitable aromatic derivatives for condensation with the sulphinic acid. This condensation takes place most readily with hydroxy- and amino-derivatives of benzene, and, since the quadrivalent sulphur grouping then enters the para-position (Smiles and Le Rossignol, *loc. cit.*) with respect to these groups, the *m*-hydroxy- and amino-benzoic acids have been employed in these experiments.

Two methods of effecting the condensation have been investigated, either with warm sulphuric acid or by the aid of heat alone (see Hinsberg, *Ber.*, 1933, **36**, 107); but since the former agent furnishes very poor yields, the latter has been generally adopted. It might be expected that the product furnished by either process would

not be the thioxanthone, but instead the oxide thereof, for example,

but this is not the case, for it appears that at the relatively high temperatures employed the sulfoxide is easily reduced to the sulphide at the expense of the sulphinic acid. In order to obtain the maximum yields of the thioxanthone, it is therefore necessary to employ an excess of sulphinic acid beyond that required by theory, and since even then the yields are not good, the method cannot be recommended for the preparation of the thioxanthenes in large quantities.

Setting out from a sulphinic acid of known constitution, it is evident that the structure to be assigned to the resulting thioxanthone must be chosen from two alternative formulæ which differ in the position taken by the sulphur with respect to the hydroxy- or amino-groups. The alternatives may be illustrated with the case of the condensation of *p*-toluenesulphinic acid with *m*-hydroxybenzoic acid:

From the general results obtained in studying the influences which govern the sulphination of hydroxy-derivatives of benzene, the second type of alternative (II) cannot be entertained as highly probable, for it has been shown that the course of this reaction is susceptible to the influence of "steric" conditions; thus, in forming a substance of type II, not only must ortho-condensation occur in preference to the more general para-condensation, but in forming the parental carboxylic acid (III) it must take place under the more adverse steric conditions. For these reasons we consider that preference must be given to the first type of formula (I), which involves the para-condensation, and the contention is supported in the case of the aminothioxanthone furnished by benzenesulphinic acid and *m*-aminobenzoic acid. The substances possessing the alternative structures in question, 2- and 4-aminothioxanthenes (IV and V), have been prepared by F. Mayer (*Ber.*, 1909, **42**, 3046) with methods which leave no room for doubt as to the constitution of the products. These substances melt respectively at 222° and

203°, whilst that obtained by ourselves melts at the temperature ascribed to the first-named isomeric. We take this opportunity

of expressing our thanks to Dr. Mayer for kindly placing at our disposal a small quantity of the 2-amino-derivative. A close comparison of this substance with that obtained by ourselves finally proved the identity of the latter.

Since there is no reason to suspect that the *o*- and *p*-toluene-sulphinic acids should behave differently from benzenesulphinic acid, a corresponding structure has been assigned to other amino- and hydroxy-derivatives of thioxanthone which have been prepared from those substances.

It is evident that the method of synthesis now described may be further varied by changing the situation of the carboxyl group in the components; thus an *o*-carboxy-sulphinic acid may be condensed with a simple aromatic compound:

but no experiments dealing with this method are described in the present paper, for a typical case has already been investigated (Davis and Smiles, *Trans.*, 1910, 97, 1290), when thioxanthone was prepared from *o*-carboxybenzenesulphinic acid and benzene.

The substances described in the experimental part of this paper are by no means the sole products of the various interactions; in fact, it is not easy with the usual methods to isolate the thioxanthenes from the impure products, and were it not for the help of a method of fractional sublimation (Christopher, *Proc.*, 1911, 27, 236) it is doubtful whether these experiments could have been brought to a successful conclusion.

EXPERIMENTAL.

An intimate mixture of 10 grams of *m*-aminobenzoic acid with 23 grams of benzenesulphinic acid was heated at 170–190° for four hours. The cold mass was boiled with aqueous sulphuric acid, and then, after being rendered alkaline with alkali hydroxide, the mixture was repeatedly extracted with ether. The united extracts were shaken with diluted sulphuric acid, and the aqueous layer,

which contained the sparingly soluble sulphate, was treated with alkali to liberate the base. The greenish-yellow precipitate was collected, and when dry it was sublimed in a vacuum. The product formed orange needles, which melted at 222° , whether heated alone or mixed with 2-aminothioxanthone obtained from another source (F. Mayer, *loc. cit.*). (Found, C=68.8; H=3.8. Calc., C=68.7; H=3.9 per cent.)

The substance also possessed the other physical properties elsewhere attributed to 2-aminothioxanthone.

2-Amino-7-methylthioxanthone,

The preparation of this substance from *m*-aminobenzoic acid and *p*-toluenesulphonic acid was conducted in the same manner as that described with 2-aminothioxanthone. However, the yields were extremely poor, and unfortunately an accident which occurred during the analysis of the small quantity available rendered invalid the estimation of hydrogen in this substance:

0.1366 gave 0.3506 CO_2 . C=70.0.

$\text{C}_{14}\text{H}_{11}\text{ONS}$ requires C=69.71 per cent.

The substance forms orange needles, which melt at 190° , whilst other physical properties are similar to those of the 2-amino-derivative.

2-Hydroxy-7-methylthioxanthone,

Interaction of 10 grams of *m*-hydroxybenzoic acid with 23 grams of *p*-toluenesulphonic acid was effected by heating the mixture at 130° during four hours. The cold mass was boiled with aqueous sodium hydroxide, and then the phenols were liberated from the solution by saturation with carbonic acid. The semi-solid precipitate was dissolved in ether, and the solution was shaken with excess of aqueous alkali hydroxide. A considerable quantity of material dissolved in the latter medium, forming a deep orange-coloured solution; this was kept for twenty-four hours, when the sparingly soluble sodium salt of the required thioxanthone separated in flocculent masses of needles. The hydroxythioxanthone obtained by treating this sodium salt with dilute mineral acid was almost pure, but it was further purified by sublimation in a vacuum. The

product, 2-hydroxy-7-methylthioxanthone, formed large, lemon-yellow needles, which showed a metallic lustre; these melted at 217° , and dissolved in concentrated sulphuric acid, imparting a brilliant green fluorescence to that medium:

0.1149 gave 0.2910 CO_2 and 0.0426 H_2O . $\text{C}=69.0$; $\text{H}=4.2$.

$\text{C}_{14}\text{H}_{10}\text{O}_2\text{S}$ requires $\text{C}=69.4$; $\text{H}=4.1$ per cent.

The sodium salt of this substance separates in orange needles from an alkaline aqueous solution of the phenol. The latter is sparingly soluble in most cold organic media, but it may be recrystallised from hot acetic acid, in which it is moderately soluble.

2-Hydroxy-5-methylthioxanthone,

The preparation of this hydroxy-derivative was conducted in the manner described in the foregoing paragraph, *m*-hydroxybenzoic and *o*-toluenesulphonic acids being heated together in quantities of 10 and 23 grams respectively. The yields obtained were somewhat poorer than with *p*-toluenesulphonic acid, partly on account of the greater solubility of the sodium salt in the alkaline medium. The product was purified as usual by sublimation in a vacuum, when it was obtained in yellow needles, which melted at 211° :

0.0755 gave 0.1926 CO_2 and 0.029 H_2O . $\text{C}=69.5$; $\text{H}=4.2$.

$\text{C}_{14}\text{H}_{10}\text{O}_2\text{S}$ requires $\text{C}=69.4$; $\text{H}=4.1$ per cent.

Other physical properties of this substance are similar to those of the 7-methyl derivative.

In some previous experiments (Davis and Smiles, *loc. cit.*) a hydroxythioxanthone was obtained by condensation of *o*-thiobenzoic acid with phenol in the presence of warm concentrated sulphuric acid. Although by heating this substance water could not be expelled from it, the suggestion was offered that it crystallises with water, for repeated fractionation did not appreciably alter the composition. In view of the fact that the methyl derivatives do not crystallise in this manner, it was considered necessary to re-investigate the simpler substance in order to determine the cause of the apparent divergence of properties. It appeared probable that an oxide of the thioxanthone might have been present as an

impurity, for observations from numerous sources have shown that sulphides are apt to be oxidised on prolonged heating with sulphuric acid; but beyond fractional crystallisation, a method of removing substances of this type from the mixture could not be devised until the formation of the methyl derivatives from the sulphinic acids had been investigated. From the alkaline mother liquors whence the sodium salts of these substances had separated, more soluble salts were isolated by adding concentrated alkali hydroxide. The substances obtained from these by mineral acids resisted all attempts at complete purification; but there is little doubt that they are the oxides of the corresponding hydroxythioxanthenes which have escaped reduction by the excess of the sulphinic acid. When heated in a vacuum at 200° they char and furnish a sublimate of the thioxanthone. The solubility of the sodium salts of these substances suggested a means of removing similar impurities from the crude hydroxythioxanthone, and the following method of preparation was adopted.

It was found that the yield of hydroxythioxanthone may be much improved by employing a relatively large quantity of phenol, for much of this substance is removed by sulphonation during the course of the interaction with *o*-thiolbenzoic acid. In other respects the condensation was effected as previously described. The product obtained by adding the mixture to water was dissolved in hot 2*N*-alkali hydroxide, and on cooling the solution the sodium salt of hydroxythioxanthone separated in orange needles. These were collected, and washed with the cold medium, in which they are almost insoluble. The purified phenol was liberated from this sodium salt with mineral acid, and it was eventually sublimed in a vacuum at 200° :

0.1067 gave 0.2655 CO_2 and 0.3569 H_2O . $\text{C}=67.9$; $\text{H}=3.7$.

$\text{C}_{15}\text{H}_8\text{O}_2\text{S}$ requires $\text{C}=68.4$; $\text{H}=3.5$ per cent.

The *hydroxythioxanthone* thus obtained forms large, lemon-yellow needles, which exhibit a metallic lustre, and melt at 243° . The substance is very sparingly soluble in most cold organic media, and its orange-coloured sodium salt is almost insoluble in cold water.

In conclusion we desire to express our thanks to the Research Fund Committee of the Society for a grant which has defrayed the cost of these experiments.

UNIVERSITY COLLEGE, LONDON.

CCXXXII. —Some Derivatives of 4(or 5)-Methylglyoxaline.

By ARTHUR JAMES EWINS.

THE recent discovery of the high degree of physiological activity attaching to the base 4(or 5)- β -aminoethylglyoxaline (Dale and Laidlaw, *J. Physiol.*, 1910, **41**, 318) and its possible therapeutic importance, has served to stimulate research in the direction of glyoxaline derivatives generally. The most interesting result so far has been the synthesis and resolution of the biochemically important amino-acid histidine (α -amino- β -glyoxaline-4(or 5)-propionic acid) by Pyman (this vol., p. 1386), who has also devised a new synthetic method of preparing the base 4(or 5)- β -aminoethylglyoxaline (this vol., p. 668) in place of the tedious and expensive method employed by Windaus and Vogt (*Ber.*, 1907, **40**, 3691). Of the numerous derivatives obtained in the course of this work, however, none was found to be possessed of physiological activity in any marked degree.

Quite recently Windaus and Opitz (*Ber.*, 1911, **44**, 1721) have obtained the alcohol 4(or 5)- β -hydroxyethylglyoxaline corresponding with the active base already mentioned, and, moreover, have synthesised 4(or 5)- β -aminomethylglyoxaline, the lower homologue of this base. From experiments carried out in these laboratories, this new base has been found, however, to be almost devoid of physiological action.

The present communication deals in the main with the synthesis of a methyl homologue of 4(or 5)- β -aminoethylglyoxaline, namely, 4(or 5)-methyl-5(or 4)- β -aminoethylglyoxaline, which it was expected might prove physiologically interesting. The structural relationship of the two bases is best seen from the following formulæ:

these bases in each case being tautomeric (compare Pyman, *Trans.* 1910, **97**, 1814).

The synthesis of this methyl homologue of 4(or 5)- β -aminoethylglyoxaline was suggested by an observation made by Windaus (*Ber.* 1909, **42**, 758). It had been recorded by O. Gerngross (*Ber.* 1909, **42**, 398) that 4(or 5)-methylglyoxaline on treatment with chloral formed an additive product, which he considered to be

4,γ,γ-trichloro-β-hydroxypropylglyoxaline, the reaction being formulated thus:

Windaus (*loc. cit.*), however, found that 4(or 5)-methylglyoxaline on treatment with formaldehyde yielded a product which on reduction gave 4:5-dimethylglyoxaline. The additive product must therefore be produced according to the equation:

The methylhydroxymethylglyoxaline so produced was not obtained by Windaus in a pure condition; but as the required 4(or 5)-methyl-5(or 4)-aminoethylglyoxaline should be readily obtainable from this hydroxy-derivative by a series of reactions analogous to those employed by Pyman in the conversion of 4(or 5)-hydroxymethylglyoxaline into 4(or 5)-β-aminoethylglyoxaline, the work of Windaus was repeated with a view to the isolation of 4(or 5)-methyl-5(or 4)-hydroxymethylglyoxaline in the pure state. This was readily accomplished after slightly modifying the conditions of Windaus's experiment, and a good yield (50 per cent. of the theory) of the base was isolated by means of its pure, crystalline picrate.

The conversion of 4(or 5)-methyl-5(or 4)-hydroxymethylglyoxaline into the required base was carried out on the lines of Pyman's synthesis, the reactions being represented thus:

For the conversion of 4(or 5)-hydroxymethylglyoxaline into the corresponding chloro-derivative Pyman employed phosphorus pentachloride. This reagent was found to be unsuitable in the case of the methyl homologue. With the hydrochloride of the chloro-derivative no reaction occurred in the cold (compare Pyman), and with the free base, or on heating with the hydrochloride, a considerable amount of charring occurred. By employing phosphoryl chloride, however, the reaction proceeded quite smoothly, and a quantitative yield of the chloro-derivative was obtained.

Like 4(or 5)-chloromethylglyoxaline, the methyl homologue is extremely reactive; thus on treating a freshly prepared ice-cold

aqueous solution of the base with a similarly cold solution of picric acid, a crystalline picrate was obtained, which was found to consist of nearly pure 4(or 5)-methyl-5(or 4)-hydroxymethylglyoxaline picrate, the chlorine atom of the base having been replaced by hydroxyl by the action of the water even at 0°.

The conversion of 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline into the corresponding cyano-compound and the reduction of the latter to the ethylamine base followed exactly on the lines of Pyman's synthesis.

By the action of cold aqueous methylamine and of cold concentrated aqueous ammonia on 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline, two other bases, namely, 4(or 5)-methyl-5(or 4)-methylaminomethylglyoxaline (I) and 4(or 5)-methyl-5(or 4)-aminomethylglyoxaline (II), were obtained, although the yields obtained were comparatively small (10—20 per cent.).

With the exception of 4(or 5)-methyl-5(or 4)-cyanomethylglyoxaline and of 4(or 5)-methyl-5(or 4)- β -aminoethylglyoxaline, all the glyoxaline derivatives obtained during the course of this investigation give an intense red colour with *p*-diazobenzenesulphonic acid in alkaline solution (Pauly's histidine reagent, *Zeitsch. physiol. Chem.*, 1904, **42**, 508). It may be also mentioned that it appears to be a general property of glyoxaline derivatives that they form phosphotungstates, which are soluble in hot water or cold acetone, and may usually be crystallised from dilute acetone, a property which is often of considerable advantage as a means of separation and purification.

The physiological action of the various bases obtained during the course of this work was investigated by Dr. P. P. Laidlaw, of these laboratories, to whom the author wishes to express his thanks. It was found that the bases 4(or 5)-methyl-5(or 4)-aminomethylglyoxaline and 4(or 5)-methyl-5(or 4)-methylaminomethylglyoxaline were physiologically almost inactive. 4(or 5)-Methyl-5(or 4)- β -aminoethylglyoxaline was, however, found to be physiologically active, chiefly in producing a decided fall in blood pressure (vasodilator effect) when injected intravenously, similar to, although somewhat less powerful than, that produced by 4(or 5)- β -aminoethylglyoxaline. It has also a weak effect on plain muscle, but its activity in this direction is far less (only about 1/200th or less) than that produced by the last-mentioned base.

EXPERIMENTAL.

Interaction of 4(or 5)-Methylglyoxaline and Formaldehyde.

Five grams of 4(or 5)-methylglyoxaline were heated in a sealed tube for two hours at 120° with 10 c.c. of a 40 per cent. solution of formaldehyde. There was no pressure on opening the tube, and to the clear, light yellow contents was added a hot saturated aqueous solution of 6.5 grams of picric acid. On cooling, a yellow, crystalline solid separated, which after recrystallisation from dilute (50 per cent.) alcohol was obtained quite pure. Yield, 9 grams.

4(or 5)-Methyl-5(or 4)-hydroxymethylglyoxaline,

The free base was obtained from the picrate by converting the latter into the hydrochloride, and treating the solution so obtained with excess of sodium carbonate. The alkaline solution was evaporated to dryness, the residue extracted with absolute alcohol, and the solution concentrated. On keeping, the crystalline base slowly separated in stout, hexagonal prisms, melting at 138°:

0.1568 gave 0.3074 CO₂ and 0.1002 H₂O. C=53.5; H=7.1.

0.3084 „ 68.2 c.c. N₂ (moist) at 23° and 758 mm. N=25.2.

C₅H₈ON₂ requires C=53.6; H=7.1; N=25.0 per cent.

The base is very readily soluble in water or alcohol, but sparingly so in most other organic solvents. Solutions of the base or of its salts give an intense cherry-red coloration with *p*-diazobenzenesulphonic acid. In neutral or alkaline solution it gives a precipitate with mercuric chloride, which is soluble in dilute acid. With phosphotungstic acid solution it gives a precipitate, which is readily soluble in hot water or cold acetone, and may readily be crystallised from dilute acetone, forming fan-shaped clusters of short, broad prisms.

The *hydrochloride*, obtained from the picrate in the usual manner, crystallises from absolute alcohol, the yield being increased by addition of a little dry ether. It forms stout, hexagonal plates, melting at 240—242°. The salt is deliquescent, and readily soluble in water or alcohol:

0.1658 gave 0.2440 CO₂ and 0.0892 H₂O. C=40.1; H=5.9.

0.1340 „ 22.4 c.c. N₂ (moist) at 23° and 758 mm. N=19.0.

0.1580 „ 0.1524 AgCl. Cl=23.8.

C₅H₈ON₂.HCl requires C=40.3; H=6.0; N=18.8;

Cl=24.0 per cent.

2056 EWINS: SOME DERIVATIVES OF 4(OR 5)-METHYLGLYOXALINE

The *picrate* obtained as described above crystallises from hot 50 per cent. alcohol in long, thin prisms, melting to a red liquid at 180—181°:

0.1374 gave 0.1938 CO₂ and 0.0410 H₂O. C=38.5; H=3.3.

0.2596 „ 47.2 c.c. N₂ (moist) at 25° and 766 mm. N=20.8.

C₈H₆ON₂.C₆H₃O₇N₃ requires C=38.7; H=3.2; N=20.6 per cent.

This salt is very sparingly soluble in cold water or alcohol, but fairly readily so in these solvents when hot.

4(or 5)-Methyl-5(or 4)-chloromethylglyoxaline,

The *hydrochloride* of this base was readily obtained as follows: Five grams of 4(or 5)-methyl-5(or 4)-hydroxymethylglyoxaline hydrochloride were suspended in about 20 c.c. of phosphoryl chloride, and the mixture gently warmed on a sand-bath under a reflux condenser. Hydrogen chloride was evolved, and solution was complete in about fifteen minutes. The excess of phosphoryl chloride was removed by distillation in a vacuum, and the residual syrupy liquid dissolved in a small quantity of hot saturated alcoholic solution of hydrogen chloride. On cooling, the crystalline hydrochloride of 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline rapidly separated. Precipitation was completed by the addition of a little dry ether. For analysis the salt was recrystallised from absolute alcohol. It forms thin, rectangular plates, melting at 222°. The yield is quantitative:

0.0776 gave 0.1014 CO₂ and 0.0328 H₂O. C=35.6; H=4.7.

0.0996 „ 0.1718 AgCl. Cl=42.7.

C₅H₇N₂Cl.HCl requires C=35.9; H=4.8; Cl=42.5 per cent.

This salt is very readily soluble in cold methyl alcohol.

4(or 5)-Methyl-5(or 4)-cyanomethylglyoxaline,

This substance was prepared from the corresponding chloro-derivative by the method which was found by Pyman (*loc. cit.*) to yield the best results with 4(or 5)-chloromethylglyoxaline. Fifteen grams less 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline hydrochloride were dissolved in 180 c.c. of absolute alcohol, and the solution slowly dropped by drop to a solution of 50 grams of potassium cyanide by about 60 c.c. of water. The mixture was kept well stirred and at a temperature of 0°. The precipitated salts were collected, washed with alcohol, and the filtrate and washings treated with

30 c.c. of saturated sodium carbonate solution. The mixture was evaporated to dryness under diminished pressure, the residue extracted with warm ethyl acetate, and the solvent evaporated. From the residual brown, syrupy liquid the 4(or 5)-methyl-5(or 4)-cyanomethylglyoxaline crystallised out on keeping. Yield, 2.7 grams (24 per cent. of the theoretical).

For analysis the base was recrystallised from water, when it was obtained in large, rectangular prisms, melting at 163--164°:

0.2274 gave 0.4954 CO₂ and 0.1264 H₂O. C=59.4; H=5.7.

0.1194 „ 34.0 c.c. N₂ (moist) at 15° and 772 mm. N=34.7.

C₆H₇N₃ requires C=59.5; H=5.8; N=34.7 per cent.

4(or 5)-Methyl-5(or 4)-cyanomethylglyoxaline is moderately soluble in cold, and very readily so in hot, water. Solutions of the base give with mercuric chloride a white precipitate, soluble in dilute acids. The *phosphotungstate* of the base is almost insoluble in cold water, but readily soluble in hot water or cold acetone. It crystallises from dilute acetone in long needles. With *p*-diazobenzenesulphonic acid in alkaline solution (sodium carbonate) an intense deep reddish-brown coloration is produced, the colour being strikingly different from that usually given by simple glyoxaline derivatives.

The *picrate* crystallises from hot water in prisms melting at 172°.

4(or 5)-Methyl-5(or 4)-β-aminoethylglyoxaline,

The reduction of 4(or 5)-methyl-5(or 4)-cyanomethylglyoxaline to the required base was carried out by means of sodium in concentrated alcoholic solution.

2.5 Grams of 4(or 5)-methyl-5(or 4)-cyanomethylglyoxaline were dissolved in a minimum quantity of absolute alcohol, and 6.5 grams of sodium was added in small portions to the gently boiling solution. Alcohol was added from time to time as necessary. The solution was then made acid to Congo-red by addition of concentrated hydrochloric acid, and the precipitated salt collected. The filtrate was rendered alkaline with sodium carbonate, evaporated to dryness, and dissolved in a little absolute alcohol. On keeping, nothing separated out, and the solution was then treated with a hot saturated solution of picric acid. The crystalline *picrate* of 4(or 5)-methyl-5(or 4)-β-aminoethylglyoxaline rapidly separated. Yield, 2.7 grams (22 per cent. of the theoretical):

0.1594 gave 0.2158 CO₂ and 0.0402 H₂O. C=36.9; H=2.8.

0.1100 „ 20.2 c.c. N₂ (moist) at 19° and 761 mm. N=21.2.

C₈H₁₁N₃.(C₆H₃O₇N₃)₂ requires C=37.0; H=2.9; N=21.6 per cent.

The *dihydrochloride* crystallises from absolute alcohol in colourless, prismatic needles, melting at 231–232°:

0.1295 gave 0.1732 CO_2 and 0.0801 H_2O . $\text{C}=36.5$; $\text{H}=6.8$.

$\text{C}_8\text{H}_{11}\text{N}_3 \cdot 2\text{HCl}$ requires $\text{C}=36.7$; $\text{H}=6.6$ per cent.

This salt is anhydrous, very sparingly soluble in hot absolute alcohol, very readily so in cold water, and fairly readily so in cold methyl alcohol. With *p*-diazobenzenesulphonic acid in alkaline solution a reddish-yellow colour is produced. The aqueous solution of the salt is precipitated by mercuric chloride, the precipitate being soluble in dilute acids. The phosphotungstate of the base is readily soluble in hot water or in cold acetone.

The *dihydrobromide* crystallises from absolute alcohol, on addition of dry ether, in stout, hexagonal prisms, melting at 212°:

0.1028 gave 0.1348 AgBr . $\text{Br}=55.8$.

$\text{C}_8\text{H}_{11}\text{N}_3 \cdot 2\text{HBr}$ requires $\text{Br}=55.8$ per cent.

4(or 5)-Methyl-5(or 4)-methylaminomethylglyoxaline,

This base was obtained by the action of methylamine on 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline.

0.5 Gram of 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline was dissolved in a few c.c. of methyl alcohol, and the solution added drop by drop to 2.5 c.c. of an aqueous solution of methylamine, which was kept at a temperature of about 0°. The solution was then evaporated to dryness, the residue dissolved in a little water, and treated with a hot saturated aqueous solution of picric acid. The heavy, yellow oil which separated from the hot solution was collected, and from the filtrate on cooling the crystalline 4(or 5)-methyl-5(or 4)-methylaminomethylglyoxaline *dipicrate* separated. It crystallises from water in prisms melting at 222°. Yield, 20 per cent. of theory:

0.1218 gave 0.1654 CO_2 and 0.0352 H_2O . $\text{C}=37.0$; $\text{H}=3.2$.

0.0944 „ 17.4 c.c. N_2 (moist) at 16° and 764 mm. $\text{N}=21.6$.

$\text{C}_8\text{H}_{11}\text{N}_3 \cdot (\text{C}_6\text{H}_3\text{O}_2\text{N}_3)_2$ requires $\text{C}=37.0$; $\text{H}=2.9$; $\text{N}=21.6$ per cent.

The *dihydrochloride* crystallises from absolute alcohol in stout prisms, melting at 246–247°:

0.1014 gave 0.1460 AgCl . $\text{Cl}=36.1$.

$\text{C}_8\text{H}_{11}\text{N}_3 \cdot 2\text{HCl}$ requires $\text{Cl}=36.2$ per cent.

4(or 5)-Methyl-5(or 4)-aminomethylglyoxaline,

This base was obtained from 4(or 5)-methyl-5(or 4)-chloromethylglyoxaline by the method employed for the preparation of the foregoing base, using concentrated aqueous ammonia (0.88) in place of methylamine. The yield of base was very poor, amounting to only 10 per cent. of the theory.

The *picrate* crystallises from hot water in clusters of well-formed prisms, melting at 216—217°.

0.0934 gave 0.1224 CO₂ and 0.0240 H₂O. C=35.7; H=2.8.

C₈H₈N₃.(C₆H₅O₇N₃)₂ requires C=35.8; H=2.6.

The *hydrochloride* crystallises from absolute alcohol in stout, rectangular prisms, melting at 233—234°.

Solutions both of this and of the foregoing base give with *p*-diazobenzenesulphonic acid an intense cherry-red colour.

The greater part of the analytical work in connexion with this investigation has been carried out by Mr. C. J. Gobell, to whom the author wishes to express his thanks.

THE WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES,
HERNE HILL, LONDON, S.E.

CXXXIII.—*The Triazo-group. Part XIX. Nitroso-azides of Dipentene, d-Limonene, and l-Limonene.*

By MARTIN ONSLOW FORSTER and FREDERIK MARINUS VAN GELDEREN.

It has been shown that the nitrosate of trimethylethylene readily exchanges the O·NO₂-group for the azoimide nucleus (this vol., p. 239), yielding the oxime of the triazoketone,

and that the nitrosochlorides of pinene and terpineol undergo a similar transformation into the corresponding nitrosoazides (*loc. cit.*, p. 244). α -Triazocamphoroxime (Trans., 1907, **91**, 874), although obtained by a different process, may be looked upon as the earliest representative of this class, and with the object of gaining further information as to the applicability of the reaction above indicated,

and the behaviour of the triazo-group in the products, we have prepared nitrosoazides of dipentene, *d*-limonene, and *l*-limonene.

The first point brought to light is the facility with which dipentene nitrosate yields the nitrosoazide, the proportion of which is greatly in excess of that derived from trimethylethylene nitrosate, and in this respect it resembles pinene nitrosochloride. Dipentene nitrosochloride also lends itself with great readiness to interaction, but the limonene nitrosoazides are associated with such a large proportion of oily by-products that the yield sinks to the neighbourhood of 20 per cent. A similar difficulty was encountered by Leach (*Trans.*, 1905, **87**, 413) in connexion with the limonene nitrosocyanides, which were accompanied by 60 per cent. of oil, even in the most favourable circumstances.

The well-known experiments of Wallach (*Annalen*, 1889, **252**, 113, and 1892, **270**, 181) dealing with the preparation of nitrolamines from the limonene nitrosochlorides, coupled with the fact that Leach isolated the α - and β -nitrosocyanides, led to the expectation that the isomeric nitrosoazides would be obtainable from each hydrocarbon; in this we were disappointed, however, only one derivative being isolated alike from the α - and the β -nitrosochlorides. As Leach's experiments showed that the yield of β -nitrosocyanide amounted to only 2 or 3 per cent., it is probable that the missing nitrosoazide is concealed in the large proportion of oil with which the crystalline product is associated.

The correspondence in structure between the new nitrosoazides and the nitrosocyanides follows from their chemical behaviour. The presence of the *isonitroso*-group is demonstrated by interaction with phenylcarbimide, although benzoyl and acetyl derivatives could not be isolated in solid form. Removal of the elements of hydrazoic acid leads to the respective carboxime, whilst application of Wallach's process of hydrolysis (*Annalen*, 1906, **346**, 231) eliminates the oximino-group, and gives rise to the corresponding triazodihydrocarvone.

As appears from the formula on p. 2061, triazodihydrocarvone belongs to the class of triazoketones in which the triazotised carbon atom is tertiary, and in accordance with the principles already developed, distinguishes itself from triazocamphor and triazocetone in its behaviour towards alcoholic alkali hydroxide, which does not set free two-thirds the azidic nitrogen, but eliminates the triazo-group in the form of alkali azide. It has been prepared in three forms, inactive from dipentene, and having strong dextro- and levorotatory power when produced from *d*- and *l*-limonenes respectively. Their oximes are, of course, the nitrosoazides from which the ketones are directly obtainable by hydrolysis; the triazoketones

yield also well-crystallised semicarbazones, but we have not been able to prepare thiosemicarbazones, semioxamazones, or phenylhydrazones. The following table summarises the physical properties of the compounds under discussion:

	Inactive.	Dextrorotatory.	Laevorotatory.
Triazodihydrocarvone	b. p. 81°/0.4 mm.	b. p. 93°/0.46 mm.	b. p. 93—94°/0.48 mm.
Oxime	m. p. 72—73°	m. p. 52—53°	m. p. 52—53°
Phenylcarbamoyloxime	m. p. 113—114°	m. p. 114—115°	m. p. 114—115°
Semicarbazone	m. p. 132—133°	m. p. 220°	m. p. 220°

It was to be expected that the reduction of triazodihydrocarvone would lead to the unknown aminoketone, or at least to the dihydropyrazine derivative corresponding with it, this alternative having been rendered probable by our experiments with the ketone from dimethylethylene nitrosoazide (this vol., p. 243). The action, however, takes a different course. Elemental nitrogen is eliminated, but the resulting aminoketone immediately loses its amino-group, which is exchanged for hydrogen, dihydrocarvone being the product. This unexpected result recalls the experience of Wallach (*Annalen*, 1898, 300, 290, and 1900, 313, 368), who encountered the same ketone among the products of reduction of the dibromide of nitrosopinene.

EXPERIMENTAL.

Dipentene Nitrosoazide, $C_{10}H_{16}(NOH) \cdot N_2$

The hydrocarbon used for these experiments boiled at $174-175^\circ$, had $D_{20}^{25} 0.8653$, and gave $n_D^{20} 1.427$ in a 2-dm. tube, whence $[\alpha]_D^{20} 1.0$. It was converted into the nitrosate and the nitrosochloride by the recognised methods, either of these materials being suitable for transformation into the nitrosoazide.

Twenty-five grams of the additive compound were covered with 50 c.c. of alcohol and a concentrated aqueous solution of sodium azide containing 15 grams; during seven days the suspended matter gradually passed into solution, crystals of sodium chloride or nitrate appearing. On pouring the mixture into cold water, the turbid product deposited crystals, the yield of nitrosoazide representing more than 80 per cent. of the theoretical amount; as the nitrosochloride of dipentene is a more economical product than the nitrosate, and there does not appear to be any difference between the two substances in their behaviour towards sodium azide, the nitrosochloride was always employed in the later experiments:

0.2513 gave 57.1 c.c. N_2 at 17° and 777 mm. $N = 27.34$.

$C_{10}H_{16}ON_4$ requires $N = 26.92$ per cent.

The substance is readily soluble in organic solvents, and is best crystallised from methyl alcohol, which deposits lustrous, rhombic plates, melting at $72-73^\circ$. It effervesces vigorously with concentrated sulphuric acid, and somewhat slowly with stannous chloride in hydrochloric acid, liberation of gas becoming more marked on warming. The nitrosoazide is volatile in steam, and is not dissolved by aqueous alkalis, which fail to remove either the oximino- or the triazo-group; with alcoholic alkali hydroxide, however, the elements of hydrazoic acid are eliminated, the product being inactive carboxime, m. p. 93° .

The *phenylcarbamyl* derivative, $C_{10}H_{16}(NO \cdot CO \cdot NH \cdot C_6H_5) \cdot N_2$, prepared by mixing molecular proportions of dipentene nitrosoazide and phenylcarbimide in dry benzene, crystallised in needles on adding petroleum, and after recrystallisation from boiling petroleum melted at $113-114^\circ$:

0.1006 gave 18.7 c.c. N_2 at 23° and 769 mm. $N = 21.69$.

$C_{17}H_{21}O_2N_5$ requires $N = 21.40$ per cent.

The substance is insoluble in cold petroleum, but dissolves readily in the hot liquid and in cold alcohol, ether, or benzene.

Attempts to hydrolyse dipentene nitrosoazide with mineral acids having shown that carvacrol is produced, the triazoketone was prepared by the action of hot aqueous oxalic acid. In quantities of 5 grams the oxime was mixed with oxalic acid (15 grams) in concentrated solution, when a current of steam carried over about 50 per cent. of a colourless oil, which was extracted with ether, dried with sodium sulphate, and distilled with the Gaede pump:

0.1740 gave 32.8 c.c. N_2 at 18° and 756 mm. $\text{N} = 22.00$.

$\text{C}_{10}\text{H}_{13}\text{ON}_3$ requires $\text{N} = 21.76$ per cent.

The triazoketone has a pleasant odour of peppermint, and rapidly becomes yellow, even when protected from light; it boils at 41° 0.4 mm., and has $D_{20}^{20} 1.0409$. Although effervescence with concentrated sulphuric acid is very vigorous, action with stannous chloride is sluggish, even on warming, and alkalis do not liberate nitrogen. When heated in alcohol with hydroxylamino acetate the triazoketone regenerates the nitrosoazido.

The *semicarbazone*, $\text{C}_{10}\text{H}_{13}(\text{N} \cdot \text{NH} \cdot \text{CO} \cdot \text{NH}_2) \cdot \text{N}_3$, prepared from *i*-triazodihydrocarvone and semicarbazide acetate in dilute alcohol, separates rapidly, and after crystallisation from benzene diluted with petroleum melts at $132\text{--}133^\circ$:

0.1450 gave 42.9 c.c. N_2 at 16° and 747 mm. $\text{N} = 34.30$.

$\text{C}_{11}\text{H}_{15}\text{ON}_4$ requires $\text{N} = 33.60$ per cent.

The substance is freely soluble in ordinary solvents, excepting petroleum.

Reduction with Aluminium Amalgam.—In the hope of obtaining the aminoketone, *i*-triazodihydrocarvone was reduced in moist ether with aluminium amalgam. Nitrogen was liberated, and about 50 per cent. of non-basic material was produced; this yielded an oxime, which after recrystallisation from alcohol melted at $112\text{--}113^\circ$:

0.1147 gave 0.3020 CO_2 and 0.1069 H_2O . $\text{C} = 71.81$; $\text{H} = 10.43$.

0.1649 „ 12.15 c.c. N_2 at 16° and 766 mm. $\text{N} = 8.77$.

$\text{C}_{10}\text{H}_{17}\text{ON}$ requires $\text{C} = 71.86$; $\text{H} = 10.18$; $\text{N} = 8.38$ per cent.

On searching for substances having this composition, it was found that the properties of the oxime correspond with those of dihydrocarboxime (Wallach, *Annalen*, 1898, **300**, 290, and 1900, **313**, 368). Hence the principal effect of reduction is to replace the triazo-group by hydrogen, a result which is quite unusual, and the aminoketone could not be recognised. A very small quantity of a basic substance was produced, however, melting at 125° , and forming a platinum

chloride decomposing at 217° ; owing to insufficiency of material, it could not be investigated further, but is probably the dihydro-pyrazine derivative corresponding with that obtained from aminocamphor and from β -triazole- β -methylbutan- γ -one (this vol., p. 239).

d-Limonene Nitrosoazide, $C_{10}H_{15}(\cdot NOH) \cdot N_3$.

The specimen of *d*-limonene employed had D^{18}_D 0.8474 , and gave α_D $102^{\circ}15'$ in a 1-dm. tube, whence $[\alpha]_D$ 120.6° . It was converted into the nitrosochlorides, which were then separated in order to ascertain whether the β -nitrosochloride gave a triazo-compound distinct from that into which the α -nitrosochloride is converted. No difference being recognised, the mixture of nitrosochlorides was used in subsequent experiments; the conditions of transformation into the nitrosoazide were the same as those observed in the preparation of dipentene nitrosoazide, excepting that the product was extracted with ether instead of being allowed to crystallise from the diluted alcoholic solution. The yield, however, was greatly inferior to that obtained from the inactive hydrocarbon, for the crystals deposited on evaporating the ether amounted to between 20 and 40 per cent. of the theoretical quantity, the remainder persisting as an oil. After recrystallisation from diluted methyl alcohol, the substance melted at $52-53^{\circ}$:

0.2283 gave 51.3 c.c. N_2 at 16° and 780 mm. $N = 27.27$.

$C_{10}H_{15}ON_4$ requires $N = 26.92$ per cent.

A solution containing 0.2970 gram, made up to 25 c.c. with chloroform, gave α_D $0^{\circ}14'$ in a 3-dm. tube, whence $[\alpha]_D$ 6.5° . It dissolves readily in the ordinary organic solvents, but is difficult to crystallise. The behaviour towards sulphuric acid and towards stannous chloride is the same as that of the inactive azide, and alcoholic alkali hydroxide gives rise to *l*-carboxime, melting at $71-72^{\circ}$, and having $[\alpha]_D$ -33° .

The *phenylcarbamyl* derivative, $C_{10}H_{15}(\cdot NO \cdot CO \cdot NH \cdot C_6H_5) \cdot N_3$ —Although attempts to benzoylate or acetylate the nitrosoazide did not lead to a solid product, phenylcarbimide was found to act readily on the substance in dry benzene, which was subsequently evaporated under reduced pressure until crystallisation began, when the residue was dissolved in methyl alcohol; this yielded crystals on slow evaporation following slight dilution, but the substance was much more difficult to isolate than the inactive isomeride. Recrystallisation from hot petroleum gave lustrous, transparent prisms, melting at $114-115^{\circ}$:

0.1508 gave 28.3 c.c. N_2 at 23° and 763 mm. $N = 21.73$.

$C_{17}H_{21}O_2N_5$ requires $N = 21.40$ per cent.

A solution containing 0.2769 gram, made up to 25 c.c. with chloroform, gave α_D^{20} 3°37' in a 3-dcm. tube, whence $[\alpha]_D^{20}$ 118.8°. The substance is freely soluble in cold solvents, excepting petroleum, from which, on slow evaporation, it crystallises in inch-long prisms; it effervesces vigorously with concentrated sulphuric acid, and more moderately with stannous chloride in hydrochloric acid.

d-Triazodihydrocarvone, $C_{10}H_{15}ON_3$.

The ketone was prepared by hydrolysing *d*-limonene nitrosoazide with hot aqueous oxalic acid, being carried over in steam, and isolated in the usual manner:

0.1908 gave 35.4 c.c. N_2 at 16° and 762 mm. $N=21.98$.

$C_{10}H_{15}ON_3$ requires $N=21.76$ per cent.

The substance boils at 93°/0.46 mm., has D^{20}_D 1.0487, and gave n_D^{20} 1.4824 in a 1-dcm. tube, whence $[\alpha]_D^{20}$ 88.49°; a solution containing 0.8234 gram, diluted to 20 c.c. with chloroform, gave α_D^{20} 11°40' in a 3-dcm. tube, whence $[\alpha]_D^{20}$ 94.4°. In chemical behaviour the ketone resembles the inactive one obtained from dipentene, and when it is heated with hydroxylamine acetate in aqueous alcohol the oxime (*d*-limonene nitrosoazide) is regenerated, m. p. 52—53°.

The semicarbazone, $C_{10}H_{15}(N \cdot NH \cdot CO \cdot NH_2) \cdot N_3$, prepared in the usual manner, showed a tendency to remain viscid; on warming with water, however, the oily impurities were removed, the white solid being then dissolved in glacial acetic acid, and precipitated with water. This treatment was repeated until the melting point was constant at 220°, decomposition occurring at this temperature:

0.2864 gave 83.0 c.c. N_2 at 19° and 761 mm. $N=33.92$.

$C_{11}H_{18}ON_6$ requires $N=33.60$ per cent.

The substance is freely soluble in ordinary solvents, excepting cold petroleum.

Reduction with Aluminium Amalgam.—As in the case of the inactive triazoketone, the principal product of reduction with aluminium amalgam in moist ether was a ketone free from nitrogen; on converting this into its oxime, the latter was found to melt at 8—89°, and appears to be identical with the active dihydrocarvone described by Wallach (*Annalen*, 1893, 275, 117). Associated with the liquid product was a very small proportion of a crystalline substance melting at 110—112°, and yielding a crystalline platinum chloride.

l-Limonene Nitrosoazide, $C_{10}H_{15}(\cdot NOH) \cdot N_2$.

The hydrocarbon used for the preparation of the nitrosochloride, had D^{20}_D 0.8465 , and gave α_D $-96^\circ 21'$ in a 1-dm. tube, whence $[\alpha]_D$ -113.8° . Proceeding as in the case of the dextrorotatory compound, the yield was again found to be very poor, a large proportion of oily by-products accompanying the solid nitrosoazide, which was recrystallised from diluted methyl alcohol, and melted at $52-53^\circ$:

0.0964 gave 23.5 c.c. N_2 at 23° and 758 mm. $N=27.56$.

$C_{10}H_{15}ON_4$ requires $N=26.92$ per cent.

We have not been able to produce a specimen of this substance with optical activity corresponding with that of the dextrorotatory isomeride; a solution containing 0.3038 gram, made up to 25 c.c. with chloroform, gave only $-2'$ in the 3-dm. tube, whence $[\alpha]_D$ less than -1° .

The *phenylcarbamyl* derivative, $C_{20}H_{25}(\cdot NO \cdot CO \cdot NH \cdot C_6H_5) \cdot N$, prepared from *l*-limonene nitrosoazide and phenylcarbimide in benzene, remained as a syrup on evaporating the solvent under reduced pressure, but treatment as before with diluted methyl alcohol followed by hot petroleum gave lustrous, woolly needles melting at $114-115^\circ$:

0.0813 gave 15.3 c.c. N_2 at 23° and 765 mm. $N=21.84$.

$C_{17}H_{21}O_2N_3$ requires $N=21.40$ per cent.

A solution containing 0.2967 gram, made up to 25 c.c. with chloroform, gave α_D $-4^\circ 18'$ in a 3-dm. tube, whence $[\alpha]_D$ -120.0° . The behaviour towards solvents, stannous chloride, and concentrated sulphuric acid is the same as that of the dextrorotatory modification.

l-Triazodihydrocarvone, $C_{10}H_{15}ON_3$.

Preparation of this triazoketone was effected by the oxalic acid method, about 60 per cent. of the amount expected being obtained.

0.1523 gave 28.6 c.c. N_2 at 18° and 761 mm. $N=22.05$.

$C_{10}H_{15}ON_3$ requires $N=21.76$ per cent.

The substance boils at $93-94^\circ/0.48$ mm., has D^{20}_D 1.0472 , and gave α_D $-96^\circ 50'$ in a 1-dm. tube at the same temperature, whence $[\alpha]_D$ -92.47° ; a solution containing 0.8278 gram, diluted to 20 c.c. with chloroform, gave α_D $-11^\circ 42'$ in a 3-dm. tube, whence $[\alpha]_D$ -94.22° . No chemical differences between this and the foregoing triazoketones were noticed, and hydroxylamine acetate regenerated *l*-limonene nitrosoazide, m. p. $52-53^\circ$.

The *semicarbazone*, $C_{10}H_{15}(\cdot N \cdot NH \cdot CO \cdot NH_2) \cdot N_3$, resembled that

of the dextrorotatory triazoketone in its tendency to remain viscid, but was purified by similar treatment, and melted and decomposed at 220° :

0.1432 gave 41.0 c.c. N_2 at 18° and 762 mm. $N = 33.67$.

$C_{11}H_{18}ON_6$ requires $N = 33.60$ per cent.

The substance is freely soluble in the ordinary solvents, excepting old petroleum.

Reduction with Aluminium Amalgam.—Treating *l*-triazodihydrocarvone with aluminium amalgam in moist ether led to a result similar to that recorded for the dextrorotatory and inactive triazo-compounds. The principal product was a non-nitrogenous ketone, identified by means of its oxime with *l*-dihydrocarvone (Wallach and Schrader, *Annalen*, 1894, 279, 381), along with a minute quantity of a basic solid.

Conversion of the Active Compounds into Derivatives of Dipentene.

Equal amounts of *d*- and *l*-limonene nitrosoazides (m. p. $52-53^{\circ}$) were mixed in methyl alcohol, heated on the water-bath during a short period, and allowed to cool, when the characteristic crystals of dipentene nitrosoazide separated in the course of a few hours; the substance melted at $72-73^{\circ}$, and did not depress the melting point of the nitrosoazide prepared from dipentene.

The *d*- and *l*-triazodihydrocarvones were mixed in ethyl alcohol, and transformed into the semicarbazone, which melted at $132-133^{\circ}$ after crystallisation from a mixture of benzene and petroleum; it was identical with the semicarbazone prepared from *i*-triazodihydrocarvone.

Pinol, prepared by the action of sodium ethoxide on terpineol bromide, was converted into the nitrosochloride, this being suspended in dilute alcohol containing sodium azide in the proportion of 4 to 9, and allowed to remain at 40° during half an hour, when the liquid had become clear; very soon afterwards lustrous crystals separated, and after recrystallisation from hot alcohol melted at 160° :

0.1866 gave 0.3704 CO_2 and 0.1231 H_2O . $\text{C}=54.13$; $\text{H}=7.38$
 0.1314 „ 28.3 c.c. N_2 at 20° and 767 mm. $\text{N}=25.34$.

$\text{C}_{10}\text{H}_{18}\text{O}_2\text{N}_4$ requires $\text{C}=53.57$; $\text{H}=7.14$; $\text{N}=25.00$ per cent.

The substance is remarkably stable for a member of this class, undergoing no change when heated with aqueous oxalic acid, from which it slowly passes over in the steam; moreover, when heated under reflux during three to four hours with dilute sulphuric acid and a few c.c. of alcohol, the greater part was recovered unchanged and the liquid exerted only feeble reducing action on Fehling's solution. It dissolves in concentrated hydrochloric acid when gently heated, being precipitated on dilution, and, in consequence we failed to isolate the corresponding triazoketone.

In conclusion, we wish to express our indebtedness to Sir William Tilden and to Messrs. Schimmel and Co. for valuable specimens with which they were so kind as to furnish us.

CCXXXIV.—*Preparation of the Betaine of Tryptophan and its Identity with the Alkaloid Hypaphorine.*

By PIETER VAN ROMBURGH and GEORGE BARGER.

WHILE working in the Botanic Gardens at Buitenzorg, in Java, the late Dr. M. Greshoff (*Mededeelingen uit 's Lands Plantentuin*, 1890, 7, 29) discovered a crystalline base in the seeds of *Erythrina Hypaphorus*, Boerl., a tree grown for the sake of its shade in the coffee plantations of Eastern Java. The base occurs in the seed to the extent of about 3 per cent., and to this "alkaloid," for which the name "hypaphorine" was suggested, the formula $\text{C}_{14}\text{H}_{18}\text{O}_2\text{N}_4$ was assigned in the "Index Phytochemicus," a list of plant substances published in 1905 by Ritsema and Sack, under the auspices of the Colonial Museum at Haarlem.

In 1891, while still at Buitenzorg, one of us (P. v. R.), at Dr. Greshoff's request, had already joined him in the investigation of the constitution of the new base, and deduced the formula $\text{C}_{14}\text{H}_{18}\text{O}_2\text{N}_4$ for it, and had further, after Dr. Greshoff's return to Holland in 1892, shown that on heating with aqueous potassium hydroxide it yielded trimethylamine and indole. The work, subsequently interrupted for many years, was resumed after Dr. Greshoff's death. The results already referred to suggested that

hypaphorine might be a betaine derived from tryptophan, and on methylating a small quantity of this amino-acid, a base was indeed obtained which showed great similarity to hypaphorine (van Romburgh, *Proc. K. Akad. Wetensch. Amsterdam*, 1911, 13, 1177). Starting from the same view as to the probable constitution of hypaphorine, the other of us working with larger quantities of tryptophan, independently prepared the same trimethyl derivative.

We have now obtained complete proof of the identity of hypaphorine with the betaine formed by methylating tryptophan, so that the alkaloid is α -trimethyl- β -indolepropionbetaine of the following constitution:

Hypaphorine is therefore a base of considerable biochemical interest. It is the first naturally occurring simple derivative of tryptophan. The absence of any pronounced physiological action and its great solubility in water differentiate it from the typical alkaloids (some of which, like strychnine and brucine, are possibly derived from tryptophan by complicated reactions). On the other hand, hypaphorine is a new member of the group of naturally occurring betaines, to which more attention has lately been directed, chiefly owing to the work of E. Schulze and his pupils. In addition to betaine itself, and to hypaphorine, this group at present contains stachydrine, trigonelline, and possibly also trimethylhistidine. The circumstance that hypaphorine is present in the seed to the extent of 3 per cent., and is readily isolated as the nitrate, might perhaps be utilised in a study of the metabolic importance of betaines in the plant, particularly in order to test the view expressed by Winterstein and Trier ("Die Alkaloide," 1910, p. 296) that betaines are merely waste products rendered innocuous by methylation. This question is the more interesting since Staněk (*Zeitsch. physiol. Chem.*, 1911, 72, 402) has recently arrived at the conclusion that betaine itself is utilised as plastic material in the young shoots and leaves of various plants.

EXPERIMENTAL.

Iodide of Methyl α -Trimethylamino- β -indolepropionate,

This ester is the first reaction product which could be isolated when tryptophan was treated with methyl iodide and sodium

2070 PREPARATION OF THE BETAINES OF TRYPTOPHAN, ETC.

hydroxide according to Engeland's method (*Ber.*, 1910, **43**, 2662). One gram of tryptophan was dissolved in 25 c.c. of methyl alcohol, and enough sodium hydroxide to render the solution slightly alkaline. After the addition of 25 c.c. of methyl iodide, the solution was gently boiled for eight hours under a reflux condenser; occasionally a little sodium hydroxide in methyl alcohol was added, in order to keep the reaction alkaline. Finally, the solution was evaporated the residual syrup at once crystallised on adding cold water 0.8 gram of crystals was thus obtained, which on recrystallisation from about 25 c.c. of boiling water yielded glistening plates, melting at 197°:

0.1702 gave 0.2923 CO₂ and 0.0805 H₂O. C=46.9; H=5.25.
0.2040 „ 13.2 c.c. N₂ (moist) at 16° and 756 mm. N=7.50.
0.2059 „ 13 c.c. N₂ „ „ 16° „ 757 mm. N=7.33.
0.1650 „ 0.0998 AgI. I=32.7.

C₁₅H₂₁O₂N₂I requires C=46.4; H=5.4; N=7.2; I=32.7 per cent

Unlike hypaphorine, the above base does not yield a sparingly soluble nitrate, but on warming for a few minutes on the water-bath with 1 per cent. aqueous sodium hydroxide, it is converted into hypaphorine; on acidification with nitric acid the nitrate of the latter base crystallises out. Conversely, on heating hypaphorine in methyl alcohol with sodium hydroxide and methyl iodide, the above-mentioned iodide of the ester is formed. The identity of the iodide from both sources was established by a melting-point determination of their mixture, and by solubility determinations:

100 grams of water at 18° dissolved 0.5015 gram of iodide from tryptophan.
100 grams of water at 18° dissolved 0.501 gram of iodide from hypaphorine.

Hypaphorine from the above Iodide.

By hydrolysis with sodium hydroxide, as described above, the iodide of the ester yielded hypaphorine, which was isolated as the nitrate. It is important to use only dilute alkali, for even then the odour of trimethylamine can be observed. On recrystallisation from hot water the nitrate melted somewhat indefinitely at 215—220°:

0.1112 gave 0.2230 CO₂ and 0.0618 H₂O. C=54.7; H=6.2.
C₁₄H₁₈O₂N₂.HNO₃ requires C=54.4; H=6.15 per cent.

The identity of the synthetic and the natural base was further established by a determination of the rotatory power of the former

A solution of 0.299 gram of the nitrate, made up with ammonia and water to 18 c.c., gave, in a 2-dm. tube, $\alpha_D + 2.50^\circ$ for

the base, whence $[\alpha]_D + 94.7^\circ$. Greshoff found $[\alpha]_D$ 91—93° for the natural base.

The close relationship of hypaphorine to tryptophan is also expressed by several qualitative reactions; both substances have reducing properties, and, as already stated by Greshoff, hypaphorine reduces gold chloride, potassium permanganate, and ferric salts in the cold. A more characteristic and very delicate reaction which both substances have in common is that of Adamkiewicz, as modified by Hopkins and Cole, namely, an intense violet coloration on the addition of glyoxylic and sulphuric acids. On the other hand, a solution of hypaphorine is readily distinguished from a tryptophan solution by the fact that, since hypaphorine is not an amino-acid, it does not give Ruhemann's reaction with triketohydrindene hydrate (Trans., 1910, 97, 1446; compare Abderhalden and Schmidt, *Zeitsch. physiol. Chem.*, 1911, 72, 37).

In spite of similarity in structure, the oxidation of hypaphorine with ferric chloride proceeds quite differently from that of tryptophan. When treated according to Hopkins and Cole's method, the latter substance readily yields β -indolealdehyde, but in several experiments we could obtain from hypaphorine only a minute quantity of a substance, insufficient for complete identification. This substance, on sublimation under greatly diminished pressure, yielded crystals closely resembling those of β -indolealdehyde (similarly sublimed), but melting indefinitely about 10° lower. Oxidation experiments with hydrogen peroxide, with and without a ferrous salt as catalyst, were likewise unsuccessful.

The methylation of tryptophan also greatly changes the behaviour of the substance with sodium hydroxide, so that hypaphorine, unlike its parent substance, readily decomposes into indole and trimethylamine.

CXXXXV.—*Dihydroxydihydrindamine and its Resolution into Optically Active Components.*

By WILLIAM JACKSON POPE and JOHN READ.

WHEN an externally compensated alkyl halogen compound condenses with ammonia to form a secondary amine the reaction may conceivably proceed in two distinct kinds of way. The resulting

secondary base may contain (1) two enantiomorphously similar alkyl groups, or (2) two enantiomorphously related alkyl groups; in case (1) the secondary amine would be externally compensated, and in case (2) it would be internally compensated. Apparently no reaction of this kind has been hitherto examined, although it is one of some little importance in connexion with the mode in which chemical change occurs between optically active substances. At first sight it might appear probable that, in the condensation referred to, both the externally compensated and the internally compensated secondary amine would be produced in approximately equal proportion; on the other hand, however, it is generally recognised that reaction between alkyl halogen compounds and ammonia is modified by steric hindrance, and it may be suggested as not impossible that steric hindrance might operate to different degrees as between two enantiomorphously similar and two enantiomorphously related molecules. If some modifying cause resembling steric hindrance were operative the externally compensated and the internally compensated secondary amine would be produced in different proportion.

For the purpose of elucidating this question we have examined the conversion of externally compensated bromohydroxyhydrindene.

the secondary amine, dihydroxydihydrindamine.

EXPERIMENTAL.

Externally Compensated Bromohydroxyhydrindene,

This substance was prepared by Krämer and Spilker (*Ber.*, 1890, 23, 3276) by the continued boiling of dibromohydrindene with dilute alcohol. This process being rather tedious and unsatisfactory, we have devised the following method for preparing bromohydroxyhydrindene, which rapidly furnishes a 70 per cent. yield of the pure substance.

Indene is well agitated with bromine water, which it immediately decolorises, and further quantities of bromine water are added until the colour is no longer discharged after prolonged shaking; in order to reduce the volume of aqueous solution used, the later quantities of bromine may be added in aqueous potassium bromide solution. The indene becomes converted into a pasty, white, crystalline mass from which the aqueous solution is poured off, and which is then

treated with light petroleum; the latter solvent extracts the oily impurity, and leaves a colourless, hard, crystalline product. On evaporating the petroleum from the extract a heavy, brown oil remains, which on repeated boiling with successive quantities of water yields a further quantity of bromohydroxyhydrindene. After crystallisation from aqueous alcohol, the pure substance is obtained in long, colourless needles, melting at $128-129^{\circ}$; on spontaneous evaporation of its solution in ethyl acetate, it is deposited in colourless, pseudo-hexagonal crystals, of which Mr. Arthur Hutchinson, M.A., has kindly furnished the following description:

Crystal system: monosymmetric— $a : b : c = 3.2080 : 1.24615 ; \beta = 60^{\circ}0'$.

Forms observed: $a\{100\}$, $c\{001\}$, $x\{101\}$, $y\{201\}$, and $v\{111\}$.

The following angular measurements were obtained:

	Measured.	Calculated.
$ac = 100 : 001$	$60^{\circ} 0'$	—
$cx = 001 : 101$	$47^{\circ} 4'$	$47^{\circ} 9'$
$cy = 001 : 201$	$79^{\circ} 59'$	$80^{\circ} 4'$
$ay = 100 : 201$	$39^{\circ} 56'$	—
$xv = 101 : 111$	$66^{\circ} 58'$	—
$av = 100 : 111$	$83^{\circ} 34'$	$83^{\circ} 22'$

The crystals are doubly terminated prisms from 5 to 10 mm. long and from 1 to 3 mm. thick. They are elongated along the diad axis, and resemble in habit crystals of the mineral epidote. The prisms a , c , and y are always present, and usually equally developed. The faces x occur but seldom, and are very narrow. The only terminal planes observed are those belonging to the form v . There is a highly perfect cleavage parallel to $c\{001\}$, and a less perfect, somewhat fibrous, cleavage parallel to $a\{100\}$. The obtuse bisectrix coincides with the diad axis. The acute bisectrix is almost normal to $a\{100\}$, and a characteristic interference figure, showing strong horizontal dispersion and an axial angle in air of approximately 52° , can be seen through these faces."

It will be noted that in the production of bromohydroxyhydrindene from indene two carbon atoms in the molecule become asymmetric, so that the former substance should exist in two externally compensated modifications. The crystalline substance just described is, however, certainly uniform, and thus can only represent one of the two possible externally compensated isomerides. We have obtained no evidence of the formation of an isomeride during the above preparation, although it is, of course, quite possible that such an isomeride may be present in the oily material formed.

Hydroxyhydrindamine and Dihydroxydihydrindamine.

Hydroxyhydrindamine, $C_6H_4 \begin{smallmatrix} \text{CH}_2 \\ \text{CH(OH)} \end{smallmatrix} \text{CH} \cdot NH_2$, and dihydroxydihydrindamine, $(C_6H_4 \begin{smallmatrix} \text{CH}_2 \\ \text{CH(OH)} \end{smallmatrix} \text{CH})_2NH$, were prepared by Spilker (*Ber.*, 1893, 26, 1542) by treating bromohydroxyhydrindene with alcoholic ammonia in the cold. This method is, however, conveniently replaced by the following process for preparing the two substances.

Bromohydroxyhydrindene (200 grams) is shaken mechanically in a stoppered Winchester bottle with ammonia (D 0.880; 860 grams); a clear solution first results, and this soon begins to deposit the secondary amine. After agitation for about two days the product is exposed in open basins until most of the ammonia has volatilised; the crude secondary base is then collected, and well washed with cold water. The filtrate and the washings are preserved, to be worked up for the preparation of the primary amine, which they contain in the form of hydrobromide.

Externally Compensated Dihydroxydihydrindamine,

The crude secondary amine (70 grams), prepared as above described, melts at about 160° ; it is dissolved in hydrochloric acid, precipitated with ammonia, and then, after collection, crystallised from alcohol. The several fractions obtained in this way consist of small, white, feathery needles, and melt rather indefinitely at about 183° ; they evidently represent the substance obtained by Spilker (*loc. cit.*), which melted at 186° .

On repeatedly extracting the substance melting at 183° with boiling ethyl acetate and recrystallising the sparingly soluble residue from boiling alcohol, a product is obtained which crystallises in small, glistening needles, and melts at 205° . This substance constitutes by far the larger proportion of the whole crude secondary amine; it is consequently to be concluded that the secondary amine now described melts at 205° , but, in the crude condition, is contaminated with some other substance which is not easily removed by recrystallisation, and which depresses the melting of the amine.

Dihydroxydihydrindamine d-Camphor- β -sulphonate.

The method just above indicated for preparing the pure externally compensated dihydroxydihydrindamine by extraction with ethyl

acetate and crystallisation of the residue from alcohol is inconvenient, and furnishes a very poor yield of the pure substance; the following process is much more satisfactory. The crude secondary amine melting at about 183° is dissolved in an alcoholic solution of the equivalent amount of *d*-camphor- β -sulphonic acid, and the alcoholic solution evaporated until crystallisation occurs. The white, crystalline mass of fine needles thus obtained is further purified by crystallisation from hot water, and then treated with ammonia to liberate the base; the secondary amine thus obtained is the pure externally compensated substance, melting at 205° .

ddl-Dihydroxydihydrindamine Platinichloride.

The externally compensated base melting at 205° yields the platinichloride when treated with platinic chloride in hydrochloric acid solution; this substance separates from hot water in glistening, orange-yellow scales, melting at 211° . It is sparingly soluble in cold water, and dissolves readily in alcohol:

0.2739 gave 0.0548 Pt. Pt=20.01.

$C_{36}H_{38}O_4N_2H_2PtCl_6$ requires Pt=20.08 per cent.

Attempts to obtain the Internally Compensated or dl-Dihydroxydihydrindamine.

The mother liquors obtained from the separation of the above-described *d*-camphor- β -sulphonate and from the ethyl acetate treatment of the original crude dihydroxydihydrindamine yield on prolonged fractional crystallisation a small proportion of a substance which is more soluble in the usual solvents than the secondary amine melting at 205° . It crystallises in colourless needles, and melts fairly sharply at 178° . The following analysis was made:

0.0862 gave 0.2431 CO_2 and 0.0543 H_2O . C=76.91; H=7.05.

$C_{18}H_{19}O_2N$ requires C=76.82; H=6.81 per cent.

The platinichloride of this substance was obtained as a yellow oil, which could not be caused to solidify.

From the facts described above it appears legitimate to conclude that the externally compensated secondary base melting at 205° is accompanied by a small proportion of the internally compensated isomeride, and that the latter melts at about 178° .

The Resolution of Externally Compensated Dihydroxydihydrindamine.

It has been shown above that on crystallising dihydroxydihydrindamine with *d*-camphor- β -sulphonic acid a partly racemic salt is formed, and that no resolution of the externally compensated base

can be effected by crystallisation with the optically active acid under ordinary conditions.

On crystallising the secondary amine melting at about 183° from an aqueous solution of the corresponding amount of *d*- α -bromocamphor- π -sulphonic acid, a partly crystalline mass is deposited which, after separation, is obtained in small, opaque nodules by crystallisation from hot water; the salt is very difficult to purify owing mainly to the ease with which hydrolytic dissociation occurs but the purification is facilitated by crystallisation from boiling ethyl acetate containing a little alcohol. The salt ultimately obtained yields, when treated with ammonia, the dextro-amine contaminated with some amount of the laevo-isomeride.

By prolonged fractional crystallisation of the crude bromocamphorsulphonate from ethyl acetate, it can be resolved into the sparingly soluble *d*-dihydroxydihydrindamine *d*- α -bromocamphor- π -sulphonate and the more readily soluble *l*-dihydroxydihydrindamine *d*- α -bromocamphor- π -sulphonate. The difference in solubility between these two salts is, however, so slight that no large proportion of the two active secondary amines can be separated in the form of the pure salts. It is most convenient to effect a rough separation by allowing about two-thirds of the salt to crystallise from ethyl acetate, and then to liberate the crude *d*-base from the sparingly soluble salt, and the crude *l*-isomeride from the mother liquors by treatment with ammonia; the optically active secondary amines are much less soluble in alcohol than is the externally compensated isomeride, and the former may easily be obtained in a state of purity by crystallising the crude bases from this solvent; thus, in one case, the mother liquors yielded a base exhibiting the specific rotatory power, $[\alpha]_{\text{H}_2\text{O}}^{25} - 52.6^{\circ}$; after one crystallisation from alcohol this value was found to be -95.7° , and a second crystallisation raised the specific rotatory power to that of the pure *l*-amine, namely, -100.0° .

d and *l*-Dihydroxydihydrindamine,

The *d*- and *l*-dihydroxydihydrindamines are sparingly soluble in boiling alcohol, and separate therefrom in long, silky needles, melting at 223° ; on crystallising equal quantities of the two isomerides together from alcohol, the externally compensated substance melting at 205° is obtained. This completes the proof that the compound described above (p. 2074) is the pure externally compensated secondary base:

RESOLUTION INTO OPTICALLY ACTIVE COMPONENTS. 2077

0.0388 of *L*-base gave 0.2503 CO₂ and 0.0556 H₂O. C=76.87; H=7.01.

C₁₈H₁₉O₄N requires C=76.82; H=6.81 per cent.

The very sparing solubility of these bases in the ordinary solvents renders it difficult to determine their rotation constants in neutral solvents; further, the substances are so feebly basic that their salts are hydrolytically dissociated with great readiness, and it is consequently difficult to ensure the purity of the solid salts. The following determinations of rotatory power were therefore made by dissolving known weights of the bases in the calculated quantities of hydrochloric acid, making up to 30.0 c.c. with water, and examining at 18° in 4 dm. tubes.

l-Dihydroxydihydrindamine.

Weight taken.		Hg ^{green} .	Hg ^{yellow} .	Na ^{yellow} .
0.0990 gram	α	- 1.32°	- 1.14°	1.10°
	$[\alpha]$	100.0	86.4	83.3
	$[M]$	281.0	243.0	234.0
0.6022 gram	α	7.88	6.78	6.53
	$[\alpha]$	98.1	84.4	81.3
	$[M]$	276.0	237.0	229.0

d-Dihydroxydihydrindamine.

0.1037 gram	α	+ 1.38°	+ 1.19°	+ 1.15°
	$[\alpha]$	99.8	86.1	83.2
	$[M]$	291.0	242.0	234.0

The mean rotatory dispersions for the basic ion in aqueous solution are thus, for Hg^{green}/Na^{yellow}=1.200, and for Hg^{yellow}/Na^{yellow}=1.037.

d- and *l*-Dihydroxydihydrindamine Platinichloride, [(C₉H₉O)₂NH]₂Pl₂Cl₆.

The platinichlorides of the active bases separate from hot water, in which they are moderately soluble, in glistening, orange needles, melting at 185°; the solutions must be kept slightly acidified with hydrochloric acid in order to prevent precipitation of the base owing to hydrolytic dissociation. The salts are readily soluble in alcohol:

0.3013 gave 0.0602 Pt. Pt=19.93.

C₃₆H₃₈O₄N₂H₂PtCl₆ requires Pt=20.08 per cent.

The following determinations of rotatory powers were made by dissolving 0.1508 gram of *d*-hydroxydihydrindamine platinichloride

in water with addition of a drop of dilute hydrochloric acid, making up to 30 c.c. with water, and examining in a 4-dcm.-tube at 18°

	Hg _{green} .	Hg _{yellow} .	Na _{yellow} .
α	- 1.12°	+ 0.95°	+ 0.63°
$[\alpha]$	55.7	47.2	46.3
$[M]/2$	271.0	230.0	225.0

The rotatory dispersions are, for $Hg_{green}/Na_{yellow} = 1.203$, and $Hg_{yellow}/Na_{yellow} = 1.019$. These values are in good agreement with those quoted above for the basic ions in hydrochloric acid solution.

1-Dihydroxydihydrindamine d- α -Bromocamphor- π -sulphonate.
(C₉H₉O)₂NH.C₁₀H₁₄OBr.SO₃H.H₂O.

This salt is conveniently obtained in a state of high purity by crystallising the *l*-base with the corresponding amount of the *d*-acid from water, and recrystallising the product from water slightly acidified with hydrochloric acid; it forms opaque clusters of minute colourless needles, melting at 210–215°:

0.0953 gave 0.1884 CO₂ and 0.0512 H₂O. C = 55.07; H = 6.14

C₂₈H₃₆O₇NBrS requires C = 55.08; H = 5.95 per cent.

0.2731 lost 0.0078 at 100°. H₂O = 2.86; 1H₂O requires 2.95.

The following determinations of rotatory power were made with the air-dried salt (1) in alcoholic solution, and (2) in water, with the addition of a drop of dilute hydrochloric acid; the weight taken was made up to 30 c.c., and the solution examined in a 4-dcm. tube at 18°.

Weight taken.		Hg _{green} .	Hg _{yellow} .	Na _{yellow} .
0.1522 gram	α	+ 0.83°	+ 0.74°	+ 0.69°
in alcohol	$[\alpha]$	43.4	36.5	34.0
	$[M]$	265.0	223.0	207.0

Rotatory dispersions: $Hg_{green}/Na_{yellow} = 1.276$; $Hg_{yellow}/Na_{yellow} = 1.074$.

0.1020 gram	α	+ 0.13°	+ 0.09°	+ 0.08°
in water	$[\alpha]$	9.6	6.6	5.9
	$[M]$	59.0	40.0	38.0
Calculated ...	$[M]$	65.4	52.3	44.5

Rotatory dispersions: $Hg_{green}/Na_{yellow} = 1.627$; $Hg_{yellow}/Na_{yellow} = 1.119$. The calculated values for the molecular rotatory power are derived from the values observed for the hydrochloric acid solutions of the base and of aqueous solutions of the ammonium salt of the acid; the observed values are low, probably owing to the presence of a slight excess of the base produced by hydrolytic dissociation.

1-Dihydroxydihydrindamine 1- α -Bromocamphor- π -sulphonate.

This salt is prepared in a state of purity in the same manner as the one previously described; it forms long, silky, colourless needles, melting at 230–232°, and is easily soluble in alcohol or ethyl acetate, and sparingly so in water:

0.0976 gave 0.1959 CO₂ and 0.0530 H₂O. C=54.71; H=6.08.

C₂₄H₃₆O₇NBrS requires C=55.05; H=5.95 per cent.

0.2360 lost 0.0071 at 100°. H₂O=3.01; 1H₂O requires 2.95.

The following determinations of rotatory power were made in the same way as those quoted for the previous salt:

Weight taken.		Hg _{green} .	Hg _{yellow} .	Na _{yellow} .
0.1525 gram	α	- 1.69°	- 1.41°	- 1.34°
in alcohol	[α]	83.1	69.8	65.9
	[M]	507.0	423.0	402.0

Rotatory dispersions: Hg_{green}/Na_{yellow} = 1.261; Hg_{yellow}/Na_{yellow} = 1.052.

0.1000 gram	α	- 1.37°	1.18°	- 1.10°
in water	[α]	102.8	88.5	82.5
	[M]	628.0	540.0	503.0
Calculated.....	[M]	628.0	538.0	513.0

Rotatory dispersions: Hg_{green}/Na_{yellow} = 1.246; Hg_{yellow}/Na_{yellow} = 1.073. The calculated values for the molecular rotatory powers were derived in the manner indicated for the previously described salt.

Externally Compensated Hydroxyhydrindamine,

In order to obtain this primary amine it is convenient to evaporate the aqueous mother liquors containing the hydrobromide, referred to on p. 2074, to dryness on the water-bath, then to dissolve in a little boiling water, and to add about twice the calculated quantity of concentrated aqueous potassium hydroxide after partial cooling. The crude amine separates as a pale yellow, crystalline precipitate, and is obtained in a state of purity by crystallisation from boiling benzene; it forms glistening, white scales, melting at 128–129°, and is quite stable in the air. It does not appear to absorb carbon dioxide and moisture from the atmosphere in the manner mentioned by Spilker (*loc. cit.*). The hydrochloride is precipitated from concentrated solutions by excess of hydrochloric acid as a white, crystalline mass; the *platinichloride* crystallises from hot water in orange needles, melting at 232°, and is readily soluble in alcohol:

0.3067 gave 0.0845 Pt. Pt=27.55.

C₁₈H₂₂O₂N₂·H₂PtCl₆ requires Pt=27.56 per cent.

The resolution of this amine into its optically active components can be effected by crystallisation with *d*- α -bromocamphor- τ -sulphonic acid, and will shortly be described.

In the treatment of externally compensated bromohydrindene with concentrated aqueous ammonia solution in the manner described above, it is converted quantitatively into a mixture of the secondary base and the primary base, hydroxyhydrindamine. In one large preparation the former product was obtained in a 55 per cent. yield, and the primary amine in a 45 per cent. yield, no unchanged material being recovered.

It is to be supposed that the first action of the ammonia is to convert bromohydroxyhydrindene into the primary externally compensated amine, hydroxyhydrindamine, and that by the action of bromohydroxyhydrindene the latter substance becomes partly converted into the secondary dihydroxydihydrindamine. We have shown that the secondary amine melting at 183° consists mainly of the externally compensated base melting at 205°, and contains but a small proportion of an isomeride melting at 178°, this being probably the internally compensated secondary amine; it therefore follows that in the formation of the secondary base condensation occurs between the alkyl bromide and hydroxyhydrindamine, which are enantiomorphously similar in molecular configuration, and that very little tendency is exhibited for condensation to occur between the hydroxyhydrindyl radicals of enantiomorphously dissimilar configurations. Representing the hydroxyhydrindyl radicle,

by the symbol R, the reaction which occurs to a preponderant extent is represented by the equations:

and

The alternative reactions represented by the equations:

and

apparently proceed to but a very slight extent.

THE CHEMICAL LABORATORY,
THE UNIVERSITY, CAMBRIDGE.

XXXXVI.—*Studies in Phototropy and Thermotropy.*
Part II. Naphthylideneamines.

By ALFRED SENIER and ROSALIND CLARKE.

In previous communications on certain Schiff's bases (Senier and Repheard, *Trans.*, 1909, **85**, 441, 1943) several of these compounds were described, some of which possessed phototropic properties, and nearly all of which were thermotropic. It was noticed that those exhibiting phototropy were all derived from salicylaldehyde, in which the substituents are in the ortho-position with respect to each other. Moreover, other investigators have shown generally that when isomerism occurs among Schiff's bases the compounds are ortho-compounds, with a few exceptions, when they are para-. This being so, it seemed interesting to continue the search for phototropy and thermotropy among compounds of this class, and, for this purpose, we have prepared and studied a number of new bases derived from 2-hydroxy- α -naphthaldehyde, in which the naphthalene nucleus takes the place of the benzene ring in salicylaldehyde. None of the bases described proved to be phototropic, but all show thermotropy in greater or less degree. At the "lower temperature" (*loc. cit.*) all become paler in colour, and at the "higher temperature" deeper; orange becomes yellow, and yellow, orange, and in the case of the aminophenol derivatives, red.

The bases, naphthylideneamines, were prepared by bringing together molecular proportions of the aldehyde and amine in alcoholic solution, and recrystallising the crystals thus obtained from that medium or from methyl alcohol.

2-Hydroxy- α -naphthylidene-o-chloroaniline,

crystallises from alcohol in yellow needles, which are sparingly soluble in ether, but readily so in acetone, chloroform, or light petroleum. It melts at $144\cdot5^\circ$ (corr.):

0.4860 gave 21.0 c.c. N_2 (moist) at 15° and 733 mm. $\text{N}=4\cdot88$.

$\text{C}_{17}\text{H}_{12}\text{ONCl}$ requires $\text{N}=4\cdot97$ per cent.

2-Hydroxy- α -naphthylidene-n-chloroaniline,

occurs as orange-yellow needles when crystallised from alcohol or light petroleum. It is sparingly soluble in ether, readily so in benzene, chloroform, or acetone, and melts at $116\text{--}117^\circ$ (corr.):

0.5222 gave 23.7 c.c. N_2 (moist) at $16\cdot5^\circ$ and 748 mm. $\text{N}=5\cdot20$.

$\text{C}_{17}\text{H}_{12}\text{ONCl}$ requires $\text{N}=4\cdot97$ per cent.

2-Hydroxy- α -naphthylidene-p-chloroaniline,

consists of yellow, silky needles, which dissolve sparingly in ether, but are readily soluble in chloroform, acetone, benzene, or light petroleum. It melts at 158—159° (corr.):

0.5558 gave 23.4 c.c. N_2 (moist) at 14° and 766 mm. $\text{N} = 4.99$.

$\text{C}_{17}\text{H}_{12}\text{ONCl}$ requires $\text{N} = 4.97$ per cent.

2-Hydroxy- α -naphthylidene-o-bromoaniline,

was obtained in yellow needles, which dissolve readily in the usual solvents. It melts at 150° (corr.):

0.5546 gave 19.9 c.c. N_2 (moist) at 14° and 780 mm. $\text{N} = 4.33$.

$\text{C}_{17}\text{H}_{12}\text{ONBr}$ requires $\text{N} = 4.30$ per cent.

2-Hydroxy- α -naphthylidene-m-bromoaniline,

crystallises in orange-yellow needles. Its behaviour towards the usual solvents is similar to that of the ortho-compound. It melts at 144° (corr.):

0.5016 gave 17.8 c.c. N_2 (moist) at 13.5° and 778 mm. $\text{N} = 4.32$.

$\text{C}_{17}\text{H}_{12}\text{ONBr}$ requires $\text{N} = 4.30$ per cent.

2-Hydroxy- α -naphthylidene-p-bromoaniline,

separates, in the first instance, in yellow leaflets, and, when recrystallised from alcohol, in pale yellow, silky needles. It dissolves readily in benzene, chloroform, acetone, or light petroleum, and less so in ether. It melts at 166.5° (corr.):

0.4930 gave 17.7 c.c. N_2 (moist) at 13° and 769 mm. $\text{N} = 4.30$.

$\text{C}_{17}\text{H}_{12}\text{ONBr}$ requires $\text{N} = 4.30$ per cent.

2-Hydroxy- α -naphthylidene-m-nitroaniline,

occurs in orange-red needles. It dissolves readily in alcohol, benzene, or chloroform, more sparingly in light petroleum. It melts at 178.5—179.5° (corr.):

0.3331 gave 27.0 c.c. N_2 (moist) at 17° and 772 mm. $\text{N} = 9.56$.

$\text{C}_{17}\text{H}_{12}\text{O}_2\text{N}_2$ requires $\text{N} = 9.59$ per cent.

2-Hydroxy- α -naphthylidene-o-aminophenol,

separates in brown crystals, which are somewhat soluble in the usual solvents, but do not readily crystallise from them. It melts and decomposes at 248—250° (corr.):

0.4777 gave 22.2 c.c. N_2 (moist) at 19° and 765 mm. $\text{N} = 5.35$.

$\text{C}_{17}\text{H}_{12}\text{O}_2\text{N}$ requires $\text{N} = 5.32$ per cent.

2-Hydroxy-α-naphthylidene-m-aminophenol,

prepared in yellow needles, which were recrystallised from alcohol. It dissolves readily in most solvents, with the exception of light petroleum, in which it is almost insoluble. It begins to melt and decompose at 221° (corr.):

0.4334 gave 19.4 c.c. N₂ (moist) at 22° and 765 mm. N = 5.11.

C₁₇H₁₃O₂N requires N = 5.32 per cent.

2-Hydroxy-α-naphthylidene-p-aminophenol,

first appeared as yellow needles, which became darker on successive recrystallisations from alcohol. It melts and decomposes at 193.5° (corr.):

0.5334 gave 26.3 c.c. N₂ (moist) at 15° and 750 mm. N = 5.65.

C₁₇H₁₃O₂N requires N = 5.32 per cent.

2-Hydroxy-α-naphthylidene-o-anisidine,

occurs as bright yellow, silky crystals, which dissolve readily in the usual solvents. It melts at 178.5° (corr.):

0.5543 gave 23.8 c.c. N₂ (moist) at 9° and 779 mm. N = 5.29.

C₁₈H₁₅O₂N requires N = 5.05 per cent.

2-Hydroxy-α-naphthylidene-m-anisidine,

forms yellow needles, which dissolve readily in the usual solvents, and melt at 107.5—108.5° (corr.):

0.4463 gave 19.3 c.c. N₂ (moist) at 17° and 762 mm. N = 5.03.

C₁₈H₁₅O₂N requires N = 5.05 per cent.

2-Hydroxy-α-naphthylidene-p-anisidine,

crystallises in clusters of long, yellow, silky needles, which are readily soluble in the usual solvents, and melt at 111—112° (corr.):

0.4798 gave 20.3 c.c. N₂ (moist) at 11.5° and 766 mm. N = 5.08.

C₁₈H₁₅O₂N requires N = 5.05 per cent.

2-Hydroxy-α-naphthylidene-o-aminobenzoic acid,

prepared in orange-yellow crystals. It is sparingly soluble in methyl alcohol, more readily so in benzene, ethyl acetate, chloroform, toluene, or light petroleum, and melts at 227.5° (corr.):

0.5014 gave 20.8 c.c. N₂ (moist) at 20° and 766 mm. N = 4.78.

C₁₈H₁₃O₃N requires N = 4.81 per cent.

2-Hydroxy-α-naphthylidene-m-aminobenzoic acid,

occurs in yellow needles, which are sparingly soluble in benzene, light petroleum, but readily so in alcohol or chloroform. It melts and decomposes at 281.5° (corr.):

0.3417 gave 14.0 c.c. N_2 (moist) at 19° and 767 mm. $N = 4.77$.
 $C_{18}H_{13}O_3N$ requires $N = 4.81$ per cent.

2-Hydroxy- α -naphthylidene-p-aminobenzoic acid,
 $OH \cdot C_{10}H_6 \cdot CH : N \cdot C_6H_4 \cdot CO_2H$,

separates in yellow crystals, which are sparingly soluble in alcohol, more readily so in chloroform, benzene, or methyl alcohol, and insoluble in light petroleum. It melts and decomposes at 295° (corr.):

0.4621 gave 19.2 c.c. N_2 (moist) at 27° and 771 mm. $N = 4.67$.
 $C_{18}H_{13}O_3N$ requires $N = 4.81$ per cent.

2-Hydroxy- α -naphthylidene-o-4-xylylidene,
 $OH \cdot C_{10}H_6 \cdot CH : N \cdot C_6H_3Me_2$,

crystallises in yellow needles, dissolves readily in the usual solvents and melts at 125.5° (corr.):

0.5746 gave 24.0 c.c. N_2 (moist) at 10° and 763 mm. $N = 5.02$.
 $C_{19}H_{17}ON$ requires $N = 5.09$ per cent.

2-Hydroxy- α -naphthylidene-m-4-xylylidene,
 $OH \cdot C_{10}H_6 \cdot CH : N \cdot C_6H_3Me_2$,

forms yellow needles, melting at 157° (corr.). Its behaviour towards solvents is similar to that of the ortho-compound:

0.4637 gave 19.8 c.c. N_2 (moist) at 15.5° and 762 mm. $N = 5.01$.
 $C_{19}H_{17}ON$ requires $N = 5.09$ per cent.

2-Hydroxy- α -naphthylidene-p-xylylidene,
 $OH \cdot C_{10}H_6 \cdot CH : N \cdot C_6H_3Me_2$,

was obtained in yellow crystals, which dissolve in the usual solvents. It melts at 108.5 – 109.5° (corr.):

0.4874 gave 21.1 c.c. N_2 (moist) at 18° and 750 mm. $N = 4.94$.
 $C_{19}H_{17}ON$ requires $N = 5.09$ per cent.

2-Hydroxy- α -naphthylidene- ψ -cumidine,
 $OH \cdot C_{10}H_6 \cdot CH : N \cdot C_6H_2Me_3$,

separates in yellow needles, which are readily soluble in alcohol, chloroform, benzene, or light petroleum, and melt at 146 – 147° (corr.):

0.5996 gave 25.2 c.c. N_2 (moist) at 15° and 759 mm. $N = 4.92$.
 $C_{20}H_{19}ON$ requires $N = 4.84$ per cent.

CXXXVII.—*Isomeric Acetaldehydephenylhydrazones.*

By ERNST GRAHAM LAWS and NEVIL VINCENT SIDGWICK.

AFTER preliminary work by Emil Fischer, and Bamherger and Pemsel, the isomeric acetaldehydephenylhydrazones were carefully investigated by Lockemann and Liesche (*Annalen*, 1905, **342**, 14), who showed that the α -form was converted into the β - by acids, and that the β - was transformed into the α -modification by alkalis, and, further, that it was not necessary for the hydrazone to pass into solution in the course of these transformations. These results are quite exceptional, and it was thought worth while to re-investigate these substances.

EXPERIMENTAL.

Preparation of the Hydrazone.

Lockemann and Liesche prepared the hydrazone in light petroleum solution, but a purer yield is obtained by using aqueous alcohol as solvent. One hundred and twenty c.c. of alcohol were mixed with 20 c.c. of water in a flask fitted with cork and upright condenser, and placed in a trough of cold water. Thirty grams of acetaldehyde were poured in, and the mixture shaken. Sixty grams of phenylhydrazine, purified by recent distillation in a vacuum, were then added in portions, the whole being shaken after each addition, and time being given to cool before adding the next. (If the mixture becomes hot, decomposition sets in, and the preparation is ruined.) Crystallisation can be induced by sowing or scratching, and the liquid should be shaken until small crystals are distributed throughout the whole mass. The apparatus is left for an hour or so to cool completely. The material is then collected, and washed with a little aqueous alcohol. The product is pure white, and does not become discoloured in air for some time. In one experiment, using the above quantities, the product when dry weighed 56 grams.

The hydrazone obtained in this way had in different experiments melting points varying between 56° and 80° , the value depending no doubt on the relative proportions of the two isomerides present. The hydrazone decomposes in air, very slowly at first, but afterwards more rapidly, becoming finally a dark brown oil. It is best stored in a vacuum over potassium hydroxide or phosphoric oxide.

Preparation of the Isomerides.

α -Form.—After recrystallisation from aqueous alcohol containing a trace of potassium hydroxide, the product invariably had a high

melting point—from 80° to 98° —the figures depending partly no doubt on the purity of the product. The highest values were obtained when the hydrazone was prepared from phenylhydrazine which had been freshly distilled, or when the product was distilled in a vacuum previous to crystallisation from alkaline alcohol; then the melting point was always above 93° , and generally 98° . This effect was always produced by a single crystallisation. The temperature to which the liquid was heated before cooling, or the time for which the heating was continued, seemed to have no effect on the transformation. The concentration of the alkali was not important provided that sufficient was present to make the liquid definitely alkaline.

β -Form.—Recrystallisation of the product from aqueous alcohol containing a trace of sulphur dioxide gave, as Lockemann and Liesche state, the β -form, melting at 56° . Great care is necessary here, for if the concentration of the acid is too great, or if the solution is heated to too high a temperature or for too long a time, decomposition sets in, and nothing can be induced to crystallise out. The solution must remain straw-coloured; if it becomes definitely yellow the preparation is spoilt. The stronger acids were found by Lockemann and Liesche to be unsuited for the purpose—an impure product was always obtained owing to decomposition. If, however, the stronger acids are used at great dilution, a pure product, melting sharply at 56° , is always obtained. Rapid recrystallisation from 75 per cent. aqueous alcohol containing two to three drops of hydrochloric acid was the method generally adopted for the preparation of the β -form.

Transformation of the Isomerides.

By recrystallisation from acidic aqueous alcohol, by immersion in aqueous acids, and by leaving the solid in an atmosphere of sulphur dioxide, the α -form (m. p. 98°) and products of intermediate melting point are converted into the β -form (m. p. 56°).

By recrystallisation from alkaline aqueous alcohol, by immersion in aqueous alkalis, and by keeping in an atmosphere of ammonia gas, the melting point of the β -form is raised considerably, although this reverse change does not always proceed sufficiently to give the pure α -product melting at 98° .

These experiments confirmed the most important points in Lockemann and Liesche's paper. In particular, it was noted that where the transformation was caused by aqueous and gaseous alkali or acid, the crystals were quite unaltered during the process, and no change in their appearance could be detected even under the microscope. The action of alkalis takes place much more slowly and often less completely than the opposite action of acids. Drying with

bosphoric oxide greatly retards the change in the case of sulphur dioxide, but drying with potassium hydroxide seems to be without effect on the action of ammonia in causing the reverse transformation.

Effect of Fusion.

Experiments in which each form was kept fused in a vacuum showed that the freezing point had not undergone any appreciable change after one hour. After six hours the freezing point of the α -form, originally 98° , had fallen to 90° , whilst that of the β -form, originally 56° , had fallen to 55° , but it was noticed that both liquids had now become discoloured.

On fusion in air the fall in freezing point and the darkening of the liquid occurred more quickly, for example, the α -form, originally fusing at 98° , melted at 55° after three hours. Working rapidly in air, two successive freezing points could be obtained with the same portion of material not differing by more than 1° .

These experiments seemed to indicate that the freezing point did not change until decomposition set in, as indicated by the darkening of the liquid.

Freezing-point Curve.—Various difficulties, due probably to the low heat of fusion of the hydrazone and to its small velocity of crystallisation, were encountered in the attempts to obtain this curve. The method finally adopted was as follows:

The mixture of α - and β -forms was made up in the required proportions in the substance tube of a Beckmann apparatus, fused completely at as low a temperature as possible, and at once withdrawn and allowed to cool in the air until crystallisation occurred. It was always stirred vigorously, so that very fine crystals were produced. The tube was then placed in position in the Beckmann apparatus, and the bath, previously regulated to a few degrees below the expected freezing point, gently heated. The substance soon became warm and more liquid. The temperature at which the last few crystals disappeared was taken. It could be determined quite accurately, for the temperature rose very slowly until all the substance had liquefied, when the rate became much greater. The solid present made the mercury in the thermometer bulb appear quite dull, but, as the last crystals dissolved, the lustre of the mercury again became visible.

This temperature is not a freezing point in the ordinary sense of the word, but a "dissolving point." The method gives the temperature at which the crystals of highest melting point dissolve in the liquid with which they are in contact. Theoretically, it should be identical with the freezing point; practically, it will tend to be above the "theoretical freezing point" (when supercooling is

nil), whereas the ordinarily determined freezing point tends to be below it.

The results obtained by this method are given in the table below :

α -Form (grams).	β -Form (grams).	α -Form, per cent.	F. p.
Set 1.			
6.0	0.0	100	98.6*
4.5	0.5	90	92.0
3.0	1.0	75	82.2
3.0	2.0	60	75.0
2.7	3.3	45	68.0
2.0	3.0	40	56.0*
Set 2.			
0.0	5.0	0	56.0*
0.9	5.1	15	59.0
1.5	3.5	30	63.2
2.0	3.0	40	65.4
2.5	2.5	50	69.8
2.0	1.0	66.6	78.0
Set 3.			
0.0	5.0	0	56.0*
0.25	4.75	5	56.8
0.5	4.5	10	57.6
1.0	4.0	20	60.0

* Inexplicable except assuming that a trace of acid was accidentally introduced.

The three sets of experiments were carried out with different preparations of the isomerides. The results are also recorded in the curve on p. 2089.

This curve indicates that the two components—the two isomerides—form a continuous series of mixed crystals (solid solutions). The curve would necessarily fall at both ends if solid solutions were not formed. So far as is known, this is the first case where this has been established, although a similar behaviour has been assumed by Hantzsch in the case of the diazonium salts and nitrophenols. The behaviour in question is due to the close similarity in properties of the two forms, which is evident from the following considerations:

Some of the pure α - and β -forms, and also crystals of various intermediate melting points, were examined under the microscope. Irregularities in the crystals prevented exact measurements being taken, but, so far as they could be tested, they appeared to be absolutely identical. Moreover, no change could be seen, even in optical properties, while a fairly large crystal of α was being converted into β under the microscope by a drop of acid.

Again, the introduction of either isomeride will effect crystallisation of the other from its supersaturated solutions; thus crystals of the α -form when introduced into a supersaturated acid solution

of the hydrazone immediately cause the crystallisation of the β -variety, and, in the same way, the introduction of the β crystals causes the α -variety to separate out from alkaline solutions. From neutral solutions, crystals of intermediate melting point are obtained by sowing with α or β , and the melting point of the product is the same whichever be used.

Further, so far as could be determined, the two isomerides have

Freezing point curve.

the same density, that of the α -form being 1.181, of the β -form 1.180, and of the mixed crystals 1.180.

Influence of the Solvent.

Lockemann and Liesche's conclusions on this question were not at all satisfactory. The method finally adopted in the present work was to recrystallise a fairly large quantity of each isomeride several times from each of the solvents investigated. The recrystallisations were done as rapidly as possible, and a fresh portion of solvent was used for each crystallisation, as hot solutions of the hydrazone soon begin to decompose when in contact with air. A sample of the hydrazone was reserved at each stage, and its freezing point determined by the method used in obtaining the above curve.

Solvent: Alcohol.

Form.	Original f.p.	Freezing point after recrystallising.			
		Once.	Twice.	Thrice.	Four times.
α	98°	83·0°	77·2°	73·2°	71°
β	56	58·0	74·0	76·0	—
mixed crystals	72	77·2	75·2	73·5	—
"	68	73·6	76·4	75·0	—
"	65	75·3	73·3	75·2	—

In each case there is a marked alteration on the first crystallisation, and then the freezing point oscillates between 73° and 77°. If the same portion of alcohol be used for the successive crystallisations, the freezing point of the α -form falls successively lower each time, whilst that of the β -form rises at first but finally falls. This behaviour is explained by the fact that a solution of the hydrazone in aqueous alcohol gradually becomes slightly acid on exposure to air. The "equilibrium values" obtained for alcohol are probably all too low, and their divergence is doubtless due to the varying amounts of acid produced in the process of each crystallisation. The experiments show that an equilibrium is reached in alcohol, but they do not indicate with certainty the value of that equilibrium.

Solvents: Benzene and Light Petroleum.—With each of these solvents the α - and β -forms remained unchanged in freezing point after three recrystallisations carried out in the above manner. Various mixtures, originally melting at points between 60° and 84°, finally gave an "equilibrium" product fusing between 82° and 83°.

Solvent: Water.

Form.	Original f.p.	Freezing point after crystallising.	
		Once.	Twice.
α	98°	81·0°	81°
β	56	80·0	81
mixed crystals	75	81·0	81
"	71	81·5	81

Water free from air was used in these experiments, as otherwise considerable oxidation occurred. These figures indicate that the isomeric change occurs rapidly in aqueous solutions, a definite equilibrium being established in the time required for a single crystallisation.

The hydrazone was found to be volatile in steam. Steam distillation gave exactly the same results as recrystallisation from water. Whatever the freezing point of the crystals used, the product invariably had a freezing point of 80—81°.

Vacuum Distillation.

Lockemann and Liesche state that each form can be distilled in vacuum, but give no details. In the following experiments the pressure was kept fairly constant at 20–21 mm.

 β -Form.

Expt.	1st Fraction.		2nd Fraction.		3rd Fraction.	
	Collected at	Freezing point.	Collected at	Freezing point.	Collected at	Freezing point.
1	133°	56·0°	133–134°	56·3°	134–135°	56·1°
2	134	56·0	134	56·2	134–135	56·2
3	133–134	56·1	134	56·0	134–135	56·3

These results indicate that the β -form distils unchanged at 133–136°/20 mm. The distillate was a pale yellow, mobile liquid, which readily solidified in the receiver. The freezing-point determinations show that there is no appreciable difference in composition between the separate fractions.

Mixed Crystals of Intermediate Composition.—The reaction product was used for these experiments. It was purified by a single crystallisation from neutral aqueous alcohol. The following result is typical of many that were obtained with crystals of different freezing points:

Freezing point of substance used.	Fraction.	Collected at	Character.	Approx. quantity.	Freezing point of fraction.
80°	A	134–135°	Mobile, colourless, froze in receiver	5 c.c.	70°
	B	135–235°	As A at first, then as C	5 „	75
	C	235–237°	Viscid, deep yellow, solidified with difficulty	5 „	96–97

These experiments show that it is, to a certain extent, possible to separate a mixture of the isomerides by this method. The temperature remains between 130° and 140°, whilst products distil over, the freezing points of which range from 56° to 70°. In the case of the mixtures of higher freezing point, such as the above, the temperature then rises quickly through 100°, during which time very little passes over. At 235° the boiling again becomes vigorous, but the character of the distillate is very different, and the freezing point indicates that it consists mainly of the α -form.

α -Form.

The following is a typical result:

Freezing point of substance used.	Fraction.	Collected at	Character.	Approx. quantity.	Freezing point.
98°	A	135—236°	Thin at first, then viscid	2—3 c.c.	92°
	B	236—237	Viscid and yellow	12 „	98—99°

The behaviour is qualitatively the same as that of the reaction product. The rapid rise occurs earlier in the experiment, and the main portion consists of the higher boiling fraction.

Discussion of Results.

The chief result of this work has been to confirm in more detail many of Lockemann and Liesche's statements. The freezing point curve definitely proves that the two forms are isomorphous, and form a continuous series of mixed crystals. They have, moreover, the same density, and undergo no physical change—even in optical properties—when transformation takes place.

Lockemann and Liesche state that the β -form rises in melting point when stored in a neutral medium, and draw the conclusion that the α -variety is the stable form. This observation could not be confirmed. Alone, whether in the solid, liquid, or gaseous state, when oxidation is prevented, each isomeride seems perfectly stable: the α - and β -forms, and all intermediate mixtures of them, undergo no change whatever, but, excepting (probably) when moisture is rigidly excluded, the presence of acid causes transformation to the lower melting end of the series of mixed crystals, whilst the presence of alkali causes the opposite transformation.

The peculiarity of the isomerism is obviously connected with the very small difference in energy content, and therefore in the relative stability of the two forms. On the other hand, there can be no doubt that the α -form is more stable in presence of alkali and the β - in presence of acid, and that a trace of acid or alkali can bring about a change from one to the other, proceeding through a mass of crystals without their passing into solution. It therefore follows that there is a difference between the crystals in contact with acid and crystals in contact with alkali. This can only come about by adsorption of acid or alkali into the crystals, which causes a difference in energy greater than the difference between the two absolutely pure forms.

No trace of acid or alkali could be found in the crystals by direct experiment, but this is not a very serious objection. The total

quantity of acid or alkali present is very small indeed, and the partition-coefficient would doubtless be greatly in favour of the water, of which there is a much larger quantity present, that is, the amount of acid or alkali in the crystals would be excessively small.

The influence of a solvent is clearly to give an equilibrium mixture. In the general case of two isomerides forming a solid solution, the stable form is, of course, one particular solid solution of a composition independent of the liquid present. The results show that the freezing point of the equilibrium mixture obtained from various solvents is as follows:

Solvent.	Freezing point of equilibrium mixture.
Light petroleum	82.5
Ether	82.8
Water	81.0
Alcohol	78.0 (highest)

The results in alcohol are untrustworthy for reasons explained above. The differences observed may be due to experimental error—traces of acid, etc.—or they may be due to adsorption of the solvent producing a similar, although smaller, effect to that of acid or alkali. The composition indicated by a freezing point of 82.5° is 75 per cent. of α and 25 per cent. of β . In this connexion it is interesting to note that Fischer described three forms of the substance in question. His third variety, melting about 80°, corresponds with this equilibrium mixture.

It seems probable that the isomerism is stereochemical. Lockemann and Liesche have pointed out that isomerism is very common in hydrazones of the type $\begin{array}{c} \text{A}-\text{C}-\text{B} \\ | \\ \text{N}\cdot\text{NH}\cdot\text{C}_6\text{H}_5 \end{array}$, but not in those of the

type $\begin{array}{c} \text{A}-\text{C}-\text{A} \\ | \\ \text{N}\cdot\text{NH}\cdot\text{C}_6\text{H}_5 \end{array}$, where stereoisomerism is excluded. The structural isomeride, benzeneazoethane, $\text{CH}_3\cdot\text{CH}_2\cdot\text{N}\cdot\text{N}\cdot\text{C}_6\text{H}_5$, has been prepared by E. Fischer, and is a red oil.

Several closely allied compounds were investigated in the same way. Acetaldehyde-*p*-bromo- and -*p*-nitro-phenylhydrazones were not found to exhibit isomerism when tested by the above methods, but a similar, although less defined, behaviour was found in the case of acetaldehyde-*p*-tolylhydrazone.

MAGDALEN COLLEGE, OXFORD.

CCXXXVIII.—Theory of Dyeing: the Colour and Molecular State of Picric Acid.

By WILLIAM PORTER DREAPER, F.I.C.

PICRIC acid in the anhydrous state is probab. colourless. It is nearly so under conditions of long exposure to the action of dehydrating agents acting through a vacuum.

In the colourless condition it has been regarded as having an *o*- or *p*-quinonoid constitution.

An investigation into variations in the conditions of formation of the colourless variety in the presence of fibre colloids (Dreaper and Stokes, *J. Soc. Dyers*, 1909, 25, 10) with the results now recorded has led to this consideration of the possible molecular structure in relation to its behaviour under these conditions. It may be mentioned that Vignon (*Rev. Gen. Mat. Col.*, 1909, 13, 156) has compared the dyeing properties of picric acid with the electrical conductivity of its solutions, and that Dreaper and Durr (*Internat. Congr. Appl. Chem.*, 1909, Sect. IVb, 7) have confirmed that picric acid in aqueous solution is not subject to de-solution when passing through a sand column. Walker and Appleby (*Trans.*, 1896, 69, 1334) have also discussed the dyeing action of picric acid on silk, and have shown that the law of the distribution of picric acid at 60° is:

$$s/\sqrt{w} = 35.5.$$

It has been assumed for the purpose in hand that the condition of attraction or strain exhibited by atoms for one another, and the attraction observed as between molecule and molecule, is identical, and in both cases can be referred back to the attraction of atoms acting at varying distances; thus, molecular attraction is regarded as primarily due to the attraction of the atoms in one molecule for those in the surrounding molecules within the active sphere of influence, and not to the attraction of molecule for molecule (see *Chem. News*, 1905, 92, 299; *Proc. Faraday Soc.*, 1910, 31). It is further assumed that the sum of the primary attraction (as between atom and atom in the same molecule) and the secondary attraction (as between an atom in one molecule and those in others) is at its maximum a constant. The secondary attraction under these conditions would increase as the primary attraction decreases.

It is assumed for the moment that the picric acid molecule is actually in association with *x* molecules of water (dihydrone or hydronol) in the coloured type. It is difficult to escape this conclu-

ion if this is the cause of a change in molecular structure, and the following facts must then be considered.

The colour intensity apparently increases to a maximum before actual solution takes place, and the ratio of the assembled molecules of water to those of picric acid has increased to a degree where such a change in physical state is involved. Change of colour is therefore not connected in this case with actual solution, unless it is assumed that the one type of picric acid is in solution in the other.

Assuming, therefore, that an association of the order suggested exists, and that this is as between atom and atom, although apparently expressed by outward molecular attraction, and, further, that this attraction under certain conditions may be localised, it will then involve either the H -, NO_2 -, OH -, or O groups. Any secondary association may then be represented as follows:

It will be observed that the last combination is the only one known to exist in the free state. It is suggested that this possible addition correspondingly induces secondary attraction of a localised order, which may then take place as between such units. The assumption that the sum of the primary and secondary attractions is a maximum value has in this respect a definite significance. The effect of such localisation will be to reduce the general attraction (as between molecule and molecule), the former taking its place. If ordinary attraction as between atom and atom be represented by localised attraction may be written as . . . and general attraction as influencing molecule and molecule as . . .

It is seen that association of this localised order is only possible with the quinone or an equivalent type. An equilibrium condition between the picric acid and water molecules may be set up, under which there is a tendency for the colourless type to be replaced by the coloured one.

It is then assumed that the secondary attraction as between the OH_2 molecules and the oxygen atom is sufficient to displace the equilibrium existing between the two types in the direction indicated, and to suppress the ordinary type in favour of the coloured one. The above attraction between the $(OH_2)_2$ molecules and the oxygen atom would under these conditions partly replace that of the H atom, and the latter would under these conditions of strain migrate to the neighbouring NO_2 group, with the formation of a compound of quinonoid type.

If this localised affinity exists, the oxygen atom, from its isolated position and the fact that it is in combination with a monatomic hydrogen atom, might favour such an action. Be this as it may,

the above consideration affords a possible explanation of the cause of the action observed if the quinone type is actually formed, and if this action is accepted as the cause of the colour change.

The solvent action of toluene when it replaces water is of a different order. In this case the colourless type is present to the virtual exclusion of the coloured one. The yellow variety dissolves to a colourless solution. It must be assumed in this case that association is of a more general order, and non-localised. There is no side-group which can associate with the solvent molecules in the manner suggested in the case of water.

By mass action the water associated with the picric acid in solution is replaced by toluene, and the colourless type is once more in stable equilibrium with the solvent.

Solutions of picric acid in water and toluene respectively may then be represented by the following types:

In the former case water is represented as being associated locally (.) as well as generally (...). The secondary association may naturally be modified by certain internal groupings, possible close-packing of the atoms, etc., with their attendant condition of strain.

It must be considered whether there is not a more convenient method of considering the change which takes place from one type to the other. If the hydrogen atom migrates, it may well carry with it its bond of attraction, and the change may then be indicated in the following manner. As the mechanism of change in intramolecular condition is apparently in this case a simple one, the change may not necessarily entail the production of the quinone type to allow of salt formation, etc.

The colour may have its origin in a change of type as indicated below in the intermediate type, which, if unstable, may then pass into the quinone type:

x may or may not equal y in this case.

Alternate methods of association may suggest themselves for comparison with the above. In the quinone type, association may be between the side-groups generally and the water molecules.

owing to position, but this does not seem to be the case in a solution in toluene; or association may take place as between the $(\text{OH}_2)_x \dots$ group and the other oxygen atom, as follows:

It will be remembered that the loss of colour has also been ascribed to the suppression of free hydrogen ions. In that case of association the presence of free or migrating ions is not impossible, owing to the reduction in the primary bond and an interchange of atoms from one molecule to the other under this condition. This action might be represented graphically in the following manner:

Association may therefore be of a general order, except where conditions are present which supply a tendency to form separate groups or independent units, and then association may be localised in the manner suggested. In the latter case the modification in the general state of equilibrium may be sufficient to disturb the general system and induce certain changes, as in the case of water and picric acid.

The salts of picric acid are coloured, and may be regarded as being of the quinone type. The association as between picric acid and animal and vegetable fibre respectively, where in the former case the change from the coloured type to the colourless does not take place in a vacuum, may possibly be expressed in the following terms:

The colour change can take place in (3), but not in (2), and in the case of silk dyed at 15° , where a certain loss of colour is observed in a vacuum, the change observed may take place in (1), which may be present at such low temperatures of dyeing. This agrees with the experimental results.

EXPERIMENTAL.

The rate of change from the coloured to the colourless type of picric acid when present on the fibres under the action of certain dehydrating agents acting in a vacuum has thus been shown to be of a definite order (Dreaper and Stokes). On vegetable fibres the change is facilitated, whilst on animal fibres it is entirely prevented.

The comparative action of water and toluene on picric acid present within the fibre area has now been examined, it being known that picric acid dissolves in toluene, giving an almost colourless solution.

Silk (fibroin) was dyed at 95° in the usual manner from an aqueous solution containing 3 per cent. of picric acid of the weight of silk taken, the ratio of silk to solution being 1:200. On immersion in toluene no change in colour or any appreciable re-solution of the dyestuff in the solvent could be observed. This result agrees with that previously obtained with the silk fibre substance and picric acid in a vacuum where this inter-relation prevents any change in type taking place under conditions on which picric acid itself loses colour. As the yellow variety of picric acid passes immediately into a colourless state on solution in toluene, the union between the picric acid and silk fibre-substance evidently prevents the normal change to the colourless type.

When cotton replaces silk, the results are of a different order from those obtained with dehydrating agents. When this fibre is coloured or stained with picric acid from a saturated aqueous solution of the latter, the picric acid is held so loosely that resolution in water is immediate, the colour being removed on agitation with water (ratio of fibre to water=1:1000) in twenty seconds. On the other hand, practically no loss occurred from the fibre area after thirty minutes' extraction with toluene at 17° , nor could any material change from the coloured to the colourless type be observed. The yellow variety is therefore stable (and insoluble) under the conditions indicated.

Following this result, it was observed that cotton may under certain conditions absorb picric acid and dye the fibre an intense yellow shade from its colourless toluene solution. This action seems to depend on the presence of oxycellulose. Under these conditions silk remains colourless, so that the dyeing properties of picric acid

in toluene as judged by colour indications are the reverse of those exhibited in aqueous solution, where the yellow variety is present within the silk area, and the cotton, except in a solution of high concentration, remains white, and absorbs no picric acid.

The silk remained colourless on evaporating the toluene, and the cotton still exhibited a full and brilliant shade of yellow. Samples treated in this manner were subjected to the action of water vapour at 100° and 15° respectively. The silk gradually assumed a yellow shade, and the cotton also visibly deepened in shade; but in water under the conditions before mentioned, the cotton still lost all its colour in twenty seconds; the silk lost about 60 per cent.

A development in shade was noticed on exposure to a damp atmosphere in the place of steam, but the rate of change from the colourless to the coloured type within the fibre area was not so rapid or so complete as after the action of the dehydrating agents, as previously recorded.

The influence of the presence of moisture in the cotton on the result obtained was next investigated. A sample was dried at 110° for one hour, and another was treated with steam before immersion in a solution of picric acid in toluene. The dried sample was much lighter in shade, and the steamed one darker. Taking the depth of shade of the ordinary cotton after treatment as 100, the dried one was represented by 70 and the steamed one by 150. After forty-eight hours' exposure of the samples so treated to the action of a saturated atmosphere at 15° , all the samples developed in colour to a standard shade, indicating that the depth of colour assumed by the fibre at the time of contact is no guide to the amount of picric acid actually absorbed, but only of the proportion of the moisture present in the cotton fibre area.

Cotton containing 6—8 per cent. of natural moisture developed a yellow shade under these conditions, whilst silk containing 10—12 per cent. of natural moisture remained colourless. The nature of the condition under which the water is present within the cotton and silk fibre area is therefore a determining factor. It is possible that in the case of silk the toluene may not penetrate into the silk substance, and therefore no absorption of picric acid can take place; but this does not agree with some of the results obtained. It may be noted that the former assumption has been held to explain certain obscure reactions which occur in the practical manipulation of these fibres.

A sample of silk was immersed in water, and all superfluous moisture carefully removed under pressure in a dry cloth. On subsequent immersion in the toluene solution the silk at once assumed a fairly deep shade of yellow, indicating that the yellow

variety can exist under these conditions in the silk fibre. The action was a non-reversible one, for after drying to remove interfering moisture the colour remained to its full intensity on subsequent immersion in toluene. When once the conditions in the animal fibre are present which determine the formation of the yellow variety, it is apparently more stable than the colourless one.

Sisley has noticed that in dilute solution the whole of the picric acid is present in the water in a mixture of water and toluene, and even in strong solution the ratio is still 4:1. The subsequent development of colour in the above samples containing varying amounts of moisture to a common shade does not indicate that the actual adsorption is directly caused by the presence of moisture. This condition seems to govern the ratio of change from the colourless type to the coloured one.

In the case of silk the natural resistance against change is probably due to the fact that the moisture present is in some close relationship with the fibre colloid, and that this prevents it from reacting with, and producing the colour change with, picric acid observed in the case of cotton; but this change can take place in the presence of water, which is not so closely associated with the fibroin. When the change has taken place as in the case of a silk fibre which obviously contained "free" moisture, some further action between the silk substance and the yellow type prevents the subsequent reversion to the colourless type in the presence of toluene.

Thus, whilst "free" moisture must be present in order that the yellow variety may exist in the silk fibre area, yet there is an adsorption of the colourless variety from toluene in its absence. This follows from the fact that on subsequent steaming the colourless silk develops a yellow shade, even after a final treatment with toluene to remove any surface picric acid which in itself might account for this action.

The relationship which exists between an animal fibre-substance and picric acid which prevents or inhibits the loss of colour on exposure to the dehydrating agents, and resists resolution and a return to the colourless type in the presence of toluene, is apparently different in the case of vegetable fibres. The action of dehydrating agents in this case causes the cotton to lose its colour, but does not do this in the presence of toluene, so that these reactions indicate in further detail the nature of the affinity which apparently exists between the fibre and the picric acid.

It may be argued that an affinity exists between the picric acid and cotton fibre-substance which prevents the normal change to the colourless type taking place in the presence of toluene; so that

Whilst the picric acid is easily removed by water from the fibre area, this action cannot take place in the case of toluene. This agrees with the assumption that the yellow variety is insoluble as such in toluene, and that the latter cannot bring about a change of type in the presence of the cotton fibre-substance. The yellow variety being soluble in water is easily removed. As picric acid will dye cotton from a toluene solution, it may be argued that this suppression of colour change is not due to any want of penetration of the solvent into the fibre.

The results obtained may be summarised in the following manner:

Nature of Fibre.	Action of dehydrating agents acting through a vacuum.	Action of toluene on picric acid within the fibre area.
Silk	No loss in colour	No loss in colour

CCXXXIX.—*Formation of Six- and Seven-membered Rings from Derivatives of 2:2'-Ditolyl.*

By JAMES KENNER and EMILY GERTRUDE TURNER.

THE general problem of the formation of closed rings from open-chain compounds has been the subject of repeated investigation, and in their broad outlines the results may be said to be capable of interpretation in terms of Bacyer's strain theory. Whilst, however, the stability, and therefore presumably the readiness of formation, of any ring is largely determined by the number of carbon atoms composing it, the relative position and nature of the substituent groups also play an important part. Although comparatively little attention has been bestowed on this side of the subject, it is possible to say: "dass im allgemeinen das Vorkommen eines quaternär gebundenen Kohlenstoffatoms die Aufspaltbarkeit zu erhöhen scheint" (Aschan, "Chemie der alicyclischen Verbindungen," 1905, p. 244), and, further, that the rupture of the ring takes place at the point where this atom occurs. It seems not impossible that the various groups attached to the carbon atom have an effect on each other similar in nature to that which is assumed to give

rise to the phenomena of steric hindrance and inhibition, or, in other words, that a more extended application of *Bayer's* theory is required. From this point of view it is to be expected that the ease with which cyclic condensation occurs will be modified by the presence in the chain of some carbon atoms which, being already members of a closed ring, have the directions of their valencies to some extent determined. The extent of this modification, should it occur, will necessarily be determined by the number of the carbon atoms of this type involved in the production of the new ring and by the degree of strain to which those of their valencies already engaged were subjected.

At the present time the compounds most easily obtainable for the study of this type of cyclic condensation are those in which certain of the carbon atoms form part of six-membered rings; thus *o*-xylene and its derivatives, the *peri*-derivatives of naphthalene and 2:2'-derivatives of diphenyl respectively contain two, three, and four such atoms. The possibility of forming rings from xylene and naphthalene has been investigated frequently, but as a result of the difficulty which formerly doubtless attended their preparation, diphenyl derivatives have received little attention. Ullmann's discovery that 2:2'-ditolyl is readily obtained by the action of copper powder on *o*-iodotoluene (*Annalen*, 1904, 332, 28) has removed the difficulty in this case, and, as the method proved to be suitable for the preparation of the compound in quantity, we were encouraged to undertake a systematic investigation of the formation of closed rings from it.

In the first place, $\omega\omega'$ -dibromo- and $\omega\omega\omega'\omega'$ -tetrabromo-2:2'-ditolyls were prepared. It was found that 2:2'-ditolyl reacted vigorously with bromine at 110°, and the dibromo-derivative was readily isolated. The further bromination was considerably more difficult, and only those preparations of the tetrabromo-derivative were successful in which the addition of the bromine extended over a period of at least two days.

The action of sodium on polymethylene dibromides is well known as a fruitful method for the synthesis of closed-ring compounds, and was shown by Haworth and Perkin (*Trans.*, 1894, 64, 599) to give excellent results when applied to hexamethylene dibromide, of which $\omega\omega'$ -dibromo-2:2'-ditolyl is a derivative. In the case of the latter substance, it was found that its ethereal solution readily reacted with sodium when the mixture was heated. The reaction to some extent followed a course similar to that observed for hexamethylene dibromide:

for the presence of dihydrophenanthrene in the product was readily shown by its oxidation to phenanthraquinone. The yield of phenanthrene derivative was not as favourable as that of *cyclohexane*, for there was also produced a colourless hydrocarbon, evidently of high molecular weight, the nature of which has not yet been determined.

Apart from the formation of the six-membered ring in this case, this reaction has the further interest that $\omega\omega'$ -dibromo-2:2'-ditolyl is a possible intermediate product* in the production of dihydrophenanthrene from *o*-bromobenzyl bromide, described by Jackson and White (*Amer. Chem. J.*, 1881, **2**, 383).

By the action of sodium on $\omega\omega\omega\omega'$ -tetrabromo-2:2'-ditolyl, phenanthrene itself was obtained in good yield:

It may be remarked that this synthesis of phenanthrene is the first in which the hydrocarbon has been obtained by a series of reactions, all of which may be carried out at comparatively low temperatures.

Attention was then directed to the isolation of compounds containing the hitherto unknown combination of a seven-membered ring with two six-membered rings. For this purpose the preparation of the ketone (I) was attempted, as the researches of Baeyer and others have shown that such cyclic ketones constitute one of the most convenient starting points for synthetical operations of this kind:

Whilst the method involving the dry distillation of the salts of

* Experiments are in progress having for their object the preparation of another possible intermediate product, 2:2'-dibromodibenzyl, in order that the behaviour of this compound may be studied.

dicarboxylic acid is perhaps the most generally applicable in such cases, it necessitates the use of considerable quantities of material. Moreover, the isolation of the heptanone derivative from the distillate might probably be difficult without some knowledge of its properties. This information we have sought to gain by attempting the production of the compound by other means before proceeding to investigate the conditions most suitable for its formation from 2:2'-ditolyl- $\omega\omega'$ -dicarboxylic acid.

2:2'-Ditolyl- $\omega\omega'$ -dicarboxylonitrile had been chosen as a source of this acid, and was prepared from $\omega\omega'$ -dibromo-2:2'-ditolyl in the manner described for *o*-phenylenediacetonitrile by Moore and Thorpe (Trans., 1908, 93, 165). It was then found that this compound could be made to undergo condensation by the method applied to *o*-phenylenediacetonitrile by these authors, and we turned our attention to this condensation as likely to provide an easier means of preparing the ketone than that originally contemplated. The condensation, effected under the influence of sodium ethoxide, leads to the production of 1-imino-2-cyano-3:5-dibenzo- $\Delta^3:5$ -cycloheptadiene* (II):

This iminocyano-compound shows considerable stability, and is only very slowly decomposed by hot aqueous potassium hydroxide. Its behaviour towards cold concentrated sulphuric acid corresponds with that of β -imino- α -cyanohydrindene, and leads to the formation

* The system of nomenclature proposed for these compounds is based on that which has been adopted in the case of compounds in which one benzene ring is combined with a seven-membered ring. The only compounds of this type described in the Transactions (Kipping and Hunter, Trans., 1901, 79, 602) are termed phenocycloheptane derivatives. The prefix "pheno" seems, however, to have been generally discarded in favour of "benzo-" (compare Thiele and Schneider, *Annalen*, 1909, 369, 288; Thiele and Weitz, *ibid.*, 1910, 377, 1; papers by Scholl, in the *Berichte*, on benzanthrone derivatives, and Aschan, "Chemie der alicyclischen Verbindungen," 1905, p. 886). Further, as the proposed generic name emphasises the derivation of these compounds from cycloheptane, any system of numbering should commence from an atom of the seven-membered ring. The choice of the particular atom is conveniently regulated by the ordinary rules of the Geneva nomenclature. The position of the "benzo-" nuclei in the heptamethylene ring is denoted according to the same plan as that in general use for double linkings. In the case of compounds containing substituents in the six-membered rings, the numbering could be continued in these rings, commencing with the carbon atom adjacent to that one

of 1-imino-3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadiene-2-carboxylic acid (III). By the action of hot dilute sulphuric acid on this compound, the desired ketone, 3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadien-1-one, was obtained. This reaction can be explained by assuming that the imino-compound is hydrolysed in the first place to the corresponding keto-compound, and this, as an α -ketonic acid, is decomposed by the dilute acid, with the loss of carbon dioxide:

These imino-compounds were not examined more closely than was necessary for the immediate purpose in view, but it was observed that they do not show the colour reactions with oxidising agents which are characteristic of the hydrindene derivatives described by Moore and Thorpe. These authors showed that the colour in the case of β -imino- α -cyanohydrindene is due to the formation of bis-1-cyano-2-hydroxyindene (IV):

It is not improbable that the failure of the reaction in the case of 1-imino-2-cyano-3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadiene (V) is due to steric causes, as it is unlikely that the carbon atom C can come within the sphere of action of a similar carbon atom in a second molecule of the compound.

The readiness with which phenanthrene was formed from of the four common to two rings which takes precedence in the numbering of the cycloheptane ring.

This system of numbering is shown in the diagram for the imino-compound referred to above:

o,o'-tetrabromo-2:2'-ditolyl made the study of condensation with the corresponding dialdehyde a matter of interest. This dialdehydodiphenyl* was readily obtained from *o,o,o',o'*-tetrabromo-2:2'-ditolyl by hydrolysis with potassium oxalate in dilute alcoholic solution. When submitted to the action of concentrated potassium hydroxide solution, on the lines of the Cannizzaro reaction, a hydroxy-acid (with its lactone) was obtained. The acid proved to be *ω*-hydroxy-2-methyldiphenyl-2'-carboxylic acid, and the analogy between this reaction and that which occurs with benzaldehyde is shown by the formulæ:

The reaction is of great interest in view of the experimental evidence adduced by Claisen (*Ber.*, 1887, 20, 646) and by Kohn and Trantom (*Trans.*, 1899, 75, 1155) in support of the hypothesis that a compound (A) is formed as an intermediate product from benzaldehyde:

The application of this conception to the condensation of 2:2'-dialdehydodiphenyl would involve either the formation of the substance (B) or a series of similar reactions in which two separate molecules condense, as illustrated by the reaction encountered in the case of terephthalaldehyde, which leads to the formation of *ω,ω'*-dihydroxy-*p*-xylene, terephthalic acid, and *ω*-hydroxy-*p*-toluic acid (Grimaux, "Jahresbericht über die Fortschritte der Chemie," 1876, 490).

Actually it would seem that (B) is the intermediate product, for *ω*-hydroxy-2-methyldiphenyl-2'-carboxylic acid loses water when

* Since this paper was written, F. Meyer has published (*Ber.*, 1911, 44, 2205) an account of the preparation of this compound from *o*-iodobenzaldehyde. The aldehyde was not obtained by him in the solid condition, but was characterised by the preparations of certain derivatives. The compound was first described by *ibid.* (Proc., 1911, 27, 92).

heated to 110° , forming an ϵ -lactone, which stands in close relationship to (B). By hydrolysis this lactone is reconverted into the hydroxy-acid.

The formation of an ϵ -lactone is so unusual that it is of interest to note that, so far as we are aware, only one other case has been recorded in which an ϵ -lactone is formed directly from the hydroxy-acid by loss of water. Baeyer and Seuffert (*Ber.*, 1899, **32**, 3619) found that β -dimethyloctan- ϵ -oic acid readily forms a lactone, whilst Baeyer and Villiger prepared this and another ϵ -lactone, and even a ζ -lactone, by the action of Caro's acid on menthone, tetrahydrocarvone, and suberone respectively.

The behaviour of 2:2'-dialdehydodiphenyl just described also agrees with that of the *o*-xylene derivative, for Thiele and Günther (*Monatsh.*, 1906, **347**, 107) mention that *o*-phthalaldehyde yields phthalide by interaction with potassium hydroxide. Further, it is well known that diphenic acid, like phthalic acid, readily yields an anhydride on dehydration with acetyl chloride, whereas adipic acid, of which diphenic acid is a substitution derivative, under the same conditions only furnishes a small amount of anhydride, even after prolonged treatment (Etiax, *Ann. Chim. Phys.*, 1896, [vii], **19**, 366); also an imide of diphenic acid, but not of adipic acid, is known. The unusual ease with which seven-membered rings are formed in these cases supports the view that the 2:2'-position in diphenyl derivatives is frequently an effective ortho position.* In this connexion Tauber's observation that 2:2'-diaminodiphenyl condenses with benzil in the same manner as *o*-diamines (*Ber.*, 1892, **25**, 3287; 1893, **26**, 1703) is not without interest.

If it be assumed that two double bonds are present in the 3:4- and 5:6-positions rather than in the 3:8- and 5:15-positions of the dibenzocycloheptadiene molecule, and that these double bonds have the usual stability associated with their presence in benzene rings, it may be pointed out that the strain, in Baeyer's sense of the word, is not nearly so large as is usually attributed to the cycloheptane ring; for the angle between any single bond and the plane of two others is $125^{\circ}16'$. The cycloheptadiene ring involved in the present case contains four such angles, together with three of $169^{\circ}28'$, amounting in all to $829^{\circ}18'$. The deficiency or total strain is therefore $70^{\circ}32'$, as contrasted with $133^{\circ}44'$ in the case of the saturated ring, and the average deviation of each of the fourteen valencies (the two valencies of each double bond being considered

* Experiments are contemplated with the object of determining to what extent this resemblance holds, for it may be expected that limitations will exist just as they are known to occur in the case of the relationship between the *peri*-position of naphthalene and the ortho-position.

to act together in such a case) becomes $5^{\circ}2'$, or rather less than the mean deviation in the cyclohexane ring. A similar calculation in the case of benzene itself reveals an average strain of $2^{\circ}38'$. In general, the presence of such double bonds would tend to diminish the strain of rings containing six or more carbon atoms, and to increase it in the case of rings containing less than six carbon atoms.

The benzoin reaction was also applied to 2:2'-dialdehydodiphenyl in the hope that intramolecular condensation might also take place in this case, leading to the formation of 9:10-dihydroxyphenanthrene:

Actually, however, it would seem that two separate molecules of dialdehydodiphenyl are concerned, for, although the amorphous product of the reaction was too ill-defined to allow of its isolation in the pure condition, it showed the reactions of a benzoin. It had reducing properties, and on oxidation was converted into an *o*-diketone, which, however, was not phenanthraquinone.

EXPERIMENTAL.

The 2:2'-ditolyl used in the following experiments was prepared according to the method described by Ullmann (*loc. cit.*) by heating equal weights of *o*-iodotoluene and copper bronze ("Naturkupfer C") under pressure at 230° . At higher temperatures the yields were not quite so good, but in all cases products of much higher boiling point accompanied the 2:2'-ditolyl.

ωω'-Dibromo-2:2'-ditolyl.

The bromination was carried out in a reflux apparatus so arranged that the bromine was introduced below the surface of the ditolyl. There was a distinct evolution of gas at 90° , but the mixture was heated at 110° in order to accelerate the reaction, which, it may be mentioned, took place more rapidly in sunlight than in the dark. After the calculated quantity of bromine had been added, the heating was continued until the evolution of gas had ceased and the dark red liquid was transparent, the temperature being raised if necessary to 120° . Neglect of this precaution in one case caused a considerable diminution in the yield. The product was kept in a vacuum desiccator over potassium hydroxide for some days while the dibromo-compound crystallised out. After adhering oil* had been separated as completely as possible, the solid was

* An attempt to utilise this oil for the preparation of the tetrabromo-derivative (p. 2112) was unsuccessful.

crystallised from acetone, being obtained in large, rhombic prisms, melting at 87.5° . The weight of pure product thus obtained amounted to two-thirds of the weight of ditolyl used:

0.1379 gave 0.2507 CO_2 and 0.0442 H_2O . $\text{C}=49.57$; $\text{H}=3.56$.

0.1868 „ 0.2083 AgBr . $\text{Br}=47.44$.

$\text{C}_{14}\text{H}_{12}\text{Br}_2$ requires $\text{C}=49.41$; $\text{H}=3.56$; $\text{Br}=47.02$ per cent.

Action of Sodium on $\omega\omega'$ -Dibromo-2:2'-ditolyl.

The dibromo-derivative dissolved in dry ether was gently boiled with successive quantities of sodium powder until the metal was no longer attacked. After decantation and removal of the ether, a mobile oil was obtained, from which after some days a minute quantity of unchanged dibromide separated. Beyond this, no separation could be obtained, an unexpected result, as dihydrophenanthrene melts at $94-95^{\circ}$ (Schmidt and Mezger, *Ber.*, 1907, **40**, 4248). To discover if this substance had been produced, a portion of the oil was treated with picric acid solution in the manner described by these authors, and the characteristic colour change from yellow to red was observed, although attempts to separate the red picrate from the excess of picric acid were unsuccessful. Eventually the yield of dihydrophenanthrene was estimated by oxidising the oil with a solution of chromic acid in glacial acetic acid, and found to be 26 per cent. The phenanthraquinone after purification melted at 205° , answered all the well known reactions, and, further, was identified by analysis. (Found, $\text{C}=80.56$; $\text{H}=3.99$. Calc., $\text{C}=80.76$; $\text{H}=3.88$ per cent.)

During the action of sodium on the ethereal solution just described, the separation of a colourless, amorphous substance was observed. This was soluble in benzene, but resisted all attempts to crystallise it, being obtained as a brittle deposit after evaporation of the solvent, and has not been examined further than to show that it is free from halogen.

2:2'-Ditolyl- $\omega\omega'$ -dicarboxylnitrile.

The methods used in the preparation of this compound and of its derivatives were essentially those applied by Moore and Thorpe (*loc. cit.*) in the case of *o*-phenylenediacetonitrile.

A saturated aqueous solution of potassium cyanide (5.2 grams) was mixed with about three times its volume of absolute alcohol. The mixture was heated to the boiling point, and to it finely powdered $\omega\omega'$ -dibromo-2:2'-ditolyl (12 grams) was added in small portions. After remaining at $50-60^{\circ}$ for some hours, water was added to the product, and the nitrile obtained as an oil which

readily solidified, and, after crystallisation from alcohol, formed rectangular blocks, melting at 77° . The yield was about 90 per cent. of the calculated amount:

0.1658 gave 17.15 c.c. N_2 at 15.5° and 747 mm. $N=12.04$.

$C_{16}H_{12}N_2$ requires $N=12.09$ per cent.

2:2'-Ditolyl- $\omega\omega'$ -dicarboxamide.

This compound was prepared by allowing the solution of the nitrile in five times its weight of concentrated sulphuric acid to remain overnight. On pouring the mixture into water and rendering the solution alkaline with ammonia, a quantity of the amide was precipitated, the weight of which was rather less than that of the nitrile used. This compound is only sparingly soluble in benzene, chloroform, or light petroleum, but dissolves readily in alcohol, from which it separates in clusters of fine needles, melting at $210-211^{\circ}$:

0.1452 gave 0.3800 CO_2 and 0.0810 H_2O . $C=71.37$; $H=6.19$.

0.1280 „ 12.1 c.c. N_2 at 25° and 752 mm. $N=10.67$.

$C_{16}H_{16}O_2N_2$ requires $C=71.64$; $H=5.97$; $N=10.45$ per cent.

2:2'-Ditolyl- $\omega\omega'$ -dicarboxylic Acid.

The hydrolysis of the amide just described was effected by boiling it with 10 per cent. potassium hydroxide solution until the evolution of ammonia, which was only slow, had ceased. After acidification, the product was repeatedly extracted with ether, and, after removal of the ether, crystallised from water. 2:2'-Ditolyl- $\omega\omega'$ -dicarboxylic acid crystallises in prisms, melting at 152° :

0.1438 gave 0.3750 CO_2 and 0.0698 H_2O . $C=71.17$; $H=5.23$.

$C_{16}H_{14}O_4$ requires $C=71.12$; $H=5.22$ per cent.

1-Imino-2-cyano-3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadiene.

To prepare the imino-compound a solution of 2:2'-ditolyl- $\omega\omega'$ -dicarboxylonitrile in four times its weight of absolute alcohol was boiled with a small amount of sodium ethoxide for one hour in a current of hydrogen. After about half an hour the imino-compound began to separate from the hot solution in colourless, prismatic crystals, and the yield amounted to over 80 per cent. of that calculated. The product melted at 189° :

0.1179 gave 0.3562 CO_2 and 0.0586 H_2O . $C=82.4$; $H=5.53$.

0.1336 „ 0.4034 CO_2 „ 0.0634 H_2O . $C=82.25$; $H=5.27$.

0.1988 „ 20.4 c.c. N_2 at 23° and 754 mm. $N=11.72$.

$C_{16}H_{12}N_2$ requires $C=82.76$; $H=5.17$; $N=12.07$ per cent.

SEVEN-MEMBERED RINGS FROM DERIVATIVES OF 2:2'-DITOLYL. 2111

As this compound does not give a colour reaction with concentrated sulphuric acid or with alcoholic potassium hydroxide, it might be expected that no advantage would result from the maintenance of an oxygen-free atmosphere during the preparation, but experience showed that better results were always obtained when hydrogen was used.

Ammonia was evolved only slowly when the imino-compound was boiled with 20 per cent. potassium hydroxide solution, and the decomposition was not complete even after two days.

1-Imino-3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadiene-2-carboxylic Acid.

A solution of 1-imino-2-cyano-3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadiene (4 grams) in cold sulphuric acid (40 c.c.) was left overnight, and then poured on to ice. After some time the precipitate was collected and found to be completely soluble in sodium hydroxide solution. The acid was therefore free from amide, and, after reprecipitation, was crystallised from dilute alcohol. It formed colourless needles, melting at 180° :

0.1910 gave 0.5328 CO_2 and 0.0890 H_2O . $\text{C}=76.08$; $\text{H}=5.18$.

0.2172 „ 11.0 c.c. N_2 at 29° and 759 mm. $\text{N}=5.68$.

$\text{C}_{16}\text{H}_{13}\text{O}_2\text{N}_2$ requires $\text{C}=76.49$; $\text{H}=5.18$; $\text{N}=5.58$ per cent.

3:5-Dibenzo- $\Delta^{3:5}$ -cycloheptadien-1-one.

A mixture of 1-imino-3:5-dibenzo- $\Delta^{3:5}$ -cycloheptadiene-2-carboxylic acid (3 grams) with 50 per cent. sulphuric acid (100 grams) was boiled in a reflux apparatus until all the solid had disappeared, a change which was complete after about one and a-half hours. By extraction with ether the ketone was isolated, being obtained as an oil, which completely solidified after some time. It separated from alcoholic solution in large, faintly yellow, hexagonal crystals, melting at $78-79^{\circ}$, but if isolated from the acid liquid by distillation with steam it is colourless. The yield was 80 per cent. of that calculated:

0.1054 gave 0.3342 CO_2 and 0.0568 H_2O . $\text{C}=86.55$; $\text{H}=5.99$.

$\text{C}_{15}\text{H}_{12}\text{O}$ requires $\text{C}=86.54$; $\text{H}=5.77$ per cent.

The *orange* crystallises in needles from dilute alcohol, and melts at 189° . For analysis it was dried at 130° :

0.2688 gave 16.2 c.c. N_2 at 27° and 750.5 mm. $\text{N}=6.58$.

$\text{C}_{15}\text{H}_{13}\text{ON}$ requires $\text{N}=6.27$ per cent.

ωωωω'-Tetrabromo-2:2'-ditolyl.

The bromination of 2:2'-ditolyl was carried out in its earlier stages at 116°, the temperature being gradually raised to 140°, and about 10 per cent. more than the calculated quantity of bromine was used. Experiments in which all the bromine was added in the course of one day repeatedly failed to give more than a minute proportion of the tetrabromo-derivative, but by arranging that the addition extended over more than two days a quantity of the tetrabromo-derivative, rather less in weight than the ditolyl used, was obtained. If the bromination had been properly conducted, the dark-coloured oil immediately became very viscous when poured into a dish, but did not crystallise when kept over potassium hydroxide in a desiccator. The mass set solid when it was treated with a little warm light petroleum, and was then crystallised from this solvent. The tetrabromo-derivative resembles the dibromo-derivative in crystalline form, and melts at 138°:

0.1612 gave 0.2015 CO₂ and 0.0302 H₂O. C=34.10; H=2.08.
C₁₄H₁₀Br₄ requires C=33.75; H=2.02 per cent.

Action of Sodium on ωωωω'-Tetrabromo-2:2'-ditolyl.

The reaction was carried out in the same manner as in the case of the dibromo-derivative. The ethereal solution from 10 grams of the tetrabromo-derivative gave 2.4 grams of crude phenanthrene (m. p. 98°). By crystallisation from 70 per cent. alcohol, the hydrocarbon was obtained in white leaflets (Found, C=94.15; H=6.00. Calc., C=94.34; H=5.66 per cent.), from which, for purposes of identification, the picrate (yellow needles, m. p. 143°) was prepared.

2:2'-Dialdehydodiphenyl.

When ωωωω'-tetrabromo-2:2'-ditolyl is heated at 130° with sulphuric acid, partial carbonisation instead of the expected hydrolysis takes place, accompanied by evolution of bromine, hydrogen bromide, and sulphur dioxide, a considerable amount of the tetrabromo-derivative being recovered unchanged. Recourse was therefore had to the method of hydrolysis described by Thiele and Günther (*Annalen*, 1906, **347**, 107) for the preparation of o-phthalaldehyde from o-xylene tetrahydromide. Ten grams of ωωωω'-tetrabromo-2:2'-ditolyl were heated in a reflux apparatus on the water-bath with 20 grams of potassium oxalate and 200 c.c. of 50 per cent. alcohol. The substance had dissolved completely after forty hours' boiling, and the pale yellow solution was then

added to twice its volume of water. The aldehyde separated after some hours, the yield amounting to that calculated.

The aldehyde is best purified by adding light petroleum (b. p. 40—60°) to its solution in ether, and is thus obtained in leaflets, colourless when pure, but frequently slightly yellow, and melting at 62°. It can also be crystallised from light petroleum (b. p. 60—80°), but the process of solution is accompanied by the formation of a considerable amount of oily matter:

0.0972 gave 0.2860 CO₂ and 0.0428 H₂O. C=80.25; H=4.89.

C₁₄H₁₀O₂ requires C=79.98; H=4.80 per cent.

The *phenylhydrazone* crystallises in rectangular prisms from alcohol, and when exposed to light changes in colour from a light yellow to a bright red:

0.1424 gave 16.2 c.c. N₂ at 26° and 756 mm. N=13.17.

0.1528 „ 16.8 c.c. N₂ „ 26° „ 756 mm. N=12.73.

C₂₀H₂₂N₄C₂H₅·OH requires N=12.88 per cent.

Action of Potassium Hydroxide on 2:2'-Dialdehydodiphenyl.

Two grams of the finely powdered aldehyde were well shaken with a cold solution of 20 grams of potassium hydroxide in 14 c.c. of water until an emulsion had been formed. After twenty-four hours the mixture was diluted and repeatedly extracted with ether in order to remove any colouring matter due to impurity in the aldehyde. The solution was then cooled and acidified. After a short time the precipitate (1.9 grams) was collected, and roughly separated into its components by treatment with ammonia solution.

The undissolved portion, purified by crystallisation from dilute alcohol, was obtained in elongated prisms, melting at 132°. From absolute alcohol it crystallised in diamond-shaped prisms:

0.1270 gave 0.3708 CO₂ and 0.0550 H₂O. C=79.63; H=4.81.

0.0714 „ 0.2080 CO₂ „ 0.0308 H₂O. C=79.45; H=4.7.

C₁₄H₁₀O₂ requires C=80.00; H=4.76 per cent.

The portion soluble in ammonia was re-precipitated by acid, and purified by repeated crystallisation from a mixture of ether and light petroleum (b. p. 40—60°), in the latter of which solvents it is sparingly soluble. It separated in small, well-defined, prismatic crystals, which melted at 146°:

0.1348 gave 0.3654 CO₂ and 0.0636 H₂O. C=73.93; H=5.24.

C₁₄H₁₂O₃ requires C=73.68; H=5.26 per cent.

The composition of the two substances thus pointed to the existence of a relationship between them of lactone to hydroxy-acid, and their intimate connexion was further illustrated by the conversion of the former substance into the latter through the agency

of potassium hydroxide solution, and by the observation that the acid substance lost the elements of water at 110° and passed into the non-acid product.

In conclusion, the authors desire to express their thanks to Professor Wynne for much encouragement and advice during the course of this work.

SHEFFIELD.

CCXI.—*Synthetical Experiments in the Group of the isoquinoline Alkaloids. Part II. The Constitution of the Condensation Products of Cotarnine and the Condensation of Cotarnine with Aliphatic and Aromatic Nitro-compounds.*

By EDWARD HOPE and ROBERT ROBINSON.

THE peculiar reactivity of cotarnine towards nitro-compounds was first observed in the case of the condensation of this substance with nitromeconine (Hope and Robinson, *Proc.*, 1910, 26, 228), whereby nitrognoscopine (nitro-*r*-narcotine) resulted, and in Part I. of this investigation an account has been given of a closely related reaction, namely, that resulting in the production of anhydrocotarnine-5-nitrophthalide (this vol., p. 1153). By elimination of the nitro-group this substance was converted into anhydrocotarninephthalide, which may also be called dedimethoxygnoscopine, and the method of synthesis of alkaloids of the isoquinoline group which was thus indicated appeared to be worthy of a detailed examination.

The object of the present communication is to place on record the preparation of a number of compounds derived from cotarnine by condensation in the main with nitrotoluenes, and some of these, and also the condensation product with nitromethane, we propose to examine further, especially with a view to their conversion into bases free from nitro-groups allied in constitution to the naturally occurring isoquinoline alkaloids.

Cotarnine condenses with particular readiness with nitromethane, and the product is a crystalline base, *anhydrocotarninenitromethane*, to which we ascribe the constitution:

Although there can be no doubt that the substance is homogeneous, two distinct methiodides are obtained by the action of methyl iodide; the one produced in larger amount is probably the normal methiodide, whilst the other, a bright yellow substance, yields trimethylamine on treatment with alkali, a fact which in conjunction with analytical data indicates it as possessing the constitution:

Nitroethane also yields a condensation product with cotarnine, but it has only been isolated in the form of its methiodide, whilst the other nitro-paraffins, such as the two nitropropanes and nitropentane, apparently react with great difficulty.

A series of nitrobenzylhydrocotarnines is produced by the condensation of cotarnine with nitrotoluenes.

The mononitro-compounds are obtained in moderate yield by the condensation of cotarnine with *o*- or *p*-nitrotoluene in the presence of sodium ethoxide in alcoholic solution. They are stable bases not decomposed on boiling with glacial acetic acid.

The dinitro-compounds are produced in almost quantitative yield by boiling an alcoholic solution of cotarnine and dinitrotoluene. 2:4:6-Trinitrotoluene on suspension in a cold alcoholic solution of cotarnine yields the theoretical amount of *anhydrocotarnine-2:4:6-trinitrotoluene*, the reaction being complete in a few seconds. Trinitro-*m*-xylene is less reactive, and cotarnine residues attach to both methyl groups, whilst with trinitromesitylene an even more sluggish reaction is observed, and the product is *dianhydrodicotarnine-trinitromesitylene*.

All these condensations occur in accordance with the following scheme, in which the case of 2:4-dinitrotoluene is represented, and the intermediate phases, referred to later, are omitted:

The cyclic constitution assigned to these condensation products is justified in this particular instance by the results obtained in examining the exhaustive methylation of the base.

Anhydrocotarnine-2:4-dinitrotoluene methiodide (I) yields, on conversion into the methochloride and treatment with alkali, the base (II), which in turn yields a methiodide. The methyl hydroxyd (III) corresponding with this salt possesses considerable stability but is slowly decomposed on boiling with water, the products being trimethylamine and the neutral substance (IV). The constitution of this final product was proved by its synthesis from cotarnone and 2:4-dinitrotoluene (see p. 2131):

The alternative view of the constitution of anhydrocotarnine-2:4-dinitrotoluene, namely:

is clearly proved to be incorrect, since the methiodide of the base correctly represented by the structure (I) is a quite different substance from the hydriodide of the stilbene derivative (II). There can be little doubt that the condensation products of cotarnine with other nitrotoluenes are also derivatives of benzylhydrocotarnine.

It is a matter of considerable interest that the bases produced from cotarnine and di- or tri-nitro-compounds are readily decomposed on boiling with glacial acetic acid, the original components being regenerated by the addition of a molecule of water. This hydrolysis can also be effected by alcoholic potassium hydroxide and is probably not due to the intermediate formation of the open chain substance (A), since the base (II) is not appreciably changed when boiled for an hour with acetic acid. The simplest scheme which represents the decomposition is the reverse of that formulated for the synthesis, but it may well be that the acid causes the group $\cdot\text{CH}_2\cdot$ to migrate to the nitrogen, a process which it is clear would be at once followed by the formation of a cotarninium salt and a dinitrotoluene.

The Mechanism of the Condensation Reactions of Cotarnine and other Pseudo-bases.

Dr. Lapworth has suggested to the authors an explanation of the condensation of aldehydes and methylene compounds in the presence of a secondary base (Knoevenagel reaction), which may be represented as follows:

In the first stage free aldehyde (or ketone) and dialkylamine unite to form the carbinol (b), which is probably in all cases in equilibrium with the ammonium hydroxide (c). In ionising solvents, the equilibrium is naturally displaced in favour of this latter form.

The positive ion of (c) can unite with the negative residue of a substance H·X, where X is any group such as ·CN, ·CH₂·NO₂, ·CH₂·C₆H₃(NO₂)₂, ·CH(CO₂Et)₂, ·CH₂·COPh, etc., and so produces the complex (d), which is very unstable, and changes to (e). When X is ·CN this represents the final stage, but in those cases where the substance H·X contains a reactive methylene group, that is, CH₃·X and CH₂XY, the further change to (f), with reproduction of the secondary base, occurs.

Finally, this unsaturated substance may add on another molecule of CH₂XY, a reaction completely analogous to the addition of ethyl sodiomalonate to αβ-unsaturated esters.

It is unnecessary to dilate on the probability of the above explanation, or to adduce specific chemical analogies for the various stages, but it may be stated that chemical literature contains experimental evidence for each of the changes involved. The spectroscopic investigations of Dobbie, Lauder, and Tinkler (Trans., 1903, 85, 598) have clearly shown that cotarnine is an equilibrium mixture of carbinol (a) and ammonium hydroxide (b), the latter predomin-

ating in alcoholic solution, whilst evidence for the open-chain aldehyde-imine structure is entirely lacking:

The proved (b) structure of cotarnine in alcoholic solution corresponds with (c) in Lapworth's explanation of the Knoevenagel reaction, and the products of condensation with substances of the type H·X have been shown (see above) to possess a hydrocotarnine-constitution, and to correspond therefore with (c). This explanation is consequently very simple in its application to the reactions of cotarnine,* requiring but one intermediate phase. The change (c) to (f) does not occur in the case of the majority of the condensation products of cotarnine, and the only example in which we suspect it is that of the condensation with dinitrophenylacetic ester (p. 2132), and even in this instance the evidence is very inconclusive.

With hydrocotarnine compounds the change in question is represented as follows:

The probable reason for the fact that unsaturated substances of this type are not produced must be sought in the stability of the ring structure.

On the basis of the above hypothesis, cotarnine, and, indeed, all pseudo-bases, should condense with any substance which is capable of giving rise to a negative ion, unless the reaction is sterically hindered, or is in opposition to the laws of thermodynamics. Various considerations will, however, affect the stage which the resulting product reaches; thus, for example, with acids there is very little or no tendency for the acid radicle to migrate to carbon. Acid amides and imides are probably partly ionised in solution, and should therefore condense with cotarnine. In point of fact a number of substances described as molecular compounds of cotarnine and amides and imides have recently been produced (Knoll & Co.).

* Cotarnine is taken throughout this discussion as an example, but the observations are intended to apply to all pseudo-bases where there is a possibility of migration of groups from the nitrogen to carbon.

D.R.P. 232785). We have examined one of them, namely, that from cotarnine and phthalimide, and our analysis proves that the substance is anhydrocotarninephthalimide, loss of water having occurred. Although this compound is immediately decomposed by acids with the production of cotarninium salts and phthalimide, we regard it as analogous to ethoxyhydrocotarnine, that is, as phthaloylaminohydrocotarnine.

In those cases where an agent has been found necessary to effect the condensation of a pseudo-base with a third substance, this agent can have no effect on the base, except to suppress its ionisation and so hinder the reaction. The agent facilitates the condensation by enabling the third substance, most probably a feeble pseudo-acid, to give rise to a negative ion. The condensation of cotarnine with *o*- or *p*-nitrotoluene in the presence of sodium ethoxide (see p. 2123) probably belongs to this category.

In conclusion, it may be mentioned that the action of magnesium alkyl haloids on cotarnine and other pseudo-bases must probably be explained by a similar idea, which is expressed in the following scheme:

EXPERIMENTAL.

Anhydrocotarninenitromethane,

This substance is prepared with great facility according to the following method:

A solution of cotarnine (20 grams) in ethyl alcohol (40 c.c.) is mixed with nitromethane (15 grams), when the temperature rises, and in about half a minute the condensation product crystallises from the liquid. After remaining an hour at the room temperature, the crystals are separated and washed with alcohol, a further quantity being obtained from the mother liquors on standing for a few days. The substance is readily soluble in boiling ethyl alcohol, and crystallises on cooling in fine, colourless prisms, melting at 129°. On analysis of a specimen dried in a vacuum:

0.1191 gave 0.2441 CO_2 and 0.0588 H_2O . $\text{C}=55.8$; $\text{H}=5.5$.

$\text{C}_{13}\text{H}_{16}\text{O}_3\text{N}_2$ requires $\text{C}=55.7$; $\text{H}=5.7$ per cent.

A characteristic property of the substance is the formation of a very sparingly soluble hydrochloride. This crystallises in needles and can be dissolved in a large excess of water. No trace of a benzoyl derivative could be isolated, whether the benzylation was carried out with benzoyl chloride in aqueous alkaline or pyridine solution.

Picrate.—The base was dissolved in acetic acid, and the solution diluted with water and treated with picric acid. The yellow precipitate was collected, and crystallised from a mixture of methyl ethyl ketone and ethyl alcohol. Long, bright yellow, slender needles were obtained, which melted at $136-137^\circ$. On analysis the substance exploded with violence in the tube, so that a high result was always obtained in a nitrogen determination.

Action of Methyl Iodide on Anhydrocotarninenitromethane.

The finely powdered substance was boiled with an excess of pure methyl iodide, when the colourless crystals were gradually replaced by a yellow gum. After three hours this transformation was complete, and the methyl iodide was removed by distillation. The gummy residue was completely dissolved in boiling methyl alcohol, and the deep yellow solution allowed to cool. A quantity of intense yellow crystals separated, and these were collected and recrystallised from methyl alcohol. The melting point of this methiodide was 229° . A specimen that had been recrystallised five times was dried in a vacuum, and analysed:

0.1381 gave 0.2125 CO_2 and 0.0655 H_2O . $\text{C}=41.9$; $\text{H}=5.3$.

0.1178 „ 0.1800 CO_2 „ 0.0560 H_2O . $\text{C}=41.7$; $\text{H}=5.3$.

0.1221 „ 0.0659 AgI . $\text{I}=29.2$.

$\text{C}_{13}\text{H}_{21}\text{O}_3\text{N}_2\text{I}$ requires $\text{C}=41.3$; $\text{H}=4.8$; $\text{I}=29.1$ per cent.

These results show that this substance is probably a *methyl anhydrocotarninenitromethane methiodide*, and has the constitution:

Proof of the correctness of this view is afforded by the examination of the products of its decomposition with alkalis. The methiodide was converted into the corresponding methochloride in the usual way by heating with silver chloride in aqueous solution and on the addition of potassium hydroxide, trimethylamine was very readily evolved. The solution was distilled, the distillate acidified with hydrochloric acid, concentrated, and treated with

platinic chloride, when a platinichloride was obtained, which melted at 238—239°, and possessed all the characteristics of trimethylamine platinichloride. We were unable to isolate the neutral decomposition product.

When the methiodide melting at 229° had been separated from the methyl-alcoholic mother liquor, another substance began to crystallise. It was at once obvious that this was a second methiodide, since it was only pale yellow in colour, and had a characteristic property of absorbing water of crystallisation. The substance was purified by many crystallisations from methyl alcohol, and was obtained in almost colourless, prismatic needles, which lose solvent on crystallisation at 110—115°, and then melt at 199°. The analytical results for this substance were unsatisfactory, since it loses some of its solvent of crystallisation on drying in the air. In order to obtain the percentage of iodine in the dry substance, determinations of the loss on heating and of the iodine were made with the same air-dried specimen:

0.7882 lost, at 120°, 0.0180 solvent. $\text{CH}_4\text{O} = 2.3$ per cent.

0.1253 gave 0.0681 AgI. $\text{I} = 30.0$ (calculated for anhydrous substance).

$\text{C}_{14}\text{H}_{10}\text{O}_5\text{N}_2\text{I}$ requires $\text{I} = 30.0$ per cent.

When a little of the substance is ground up with water, it swells up and becomes a mass of pale yellow needles. It was recrystallised from water, dried in air, and the loss on heating determined:

0.9774 lost 0.0516 H_2O . $\text{H}_2\text{O} = 5.2$.

$\text{C}_{14}\text{H}_{10}\text{O}_5\text{N}_2\text{I} \cdot \text{H}_2\text{O}$ requires $\text{H}_2\text{O} = 4.1$ per cent.

The substance melted at 105—115°, then re-solidified, and melted at 196—198°. On decomposition of this methiodide with alkali practically no volatile base was obtained; it gave the merest trace of a platinichloride, melting at 228°.

All the above observations are in agreement with the hypothesis that this second methiodide is the normal methiodide of anhydrotarninenitromethane. It can be represented by either of the following formulæ, but we prefer the first, and regard the production of the yellow methiodide as occurring by the opening of the isoquinoline ring:

Further experiments have been made, and will be made, on this base, in respect, for example, of its reduction products, but it is hoped that they will form the subject-matter of a future communi-

cation. In the meantime we have represented the substance as a derivative of hydrocotarnine, the chief arguments in favour of this view being its lack of visible colour and the formation of a normal methiodide.

Anhydrocotarninenitroethane Methiodide,

Cotarnine (6 grams) was dissolved in alcohol, and the solution boiled for ten minutes with nitroethane (1.9 grams). On evaporating a portion of the solution, a gummy residue was obtained, and this could not be induced to crystallise. That a condensation had occurred was proved by the following experiments. In the first place, a solution of the gum in dilute hydrochloric acid gave, on addition of picric acid, a bright yellow precipitate of a picrate which crystallised from acetone in greenish-yellow prisms, melting at 114—116°. This could not be cotarnine picrate, and was therefore the picrate of a condensation product. The main portion of the gum was treated with boiling methyl iodide, when a methiodide was produced, and became solid in contact with cold methyl alcohol. After separation, the substance was crystallised from methyl alcohol, and was obtained in pale yellow, rectangular plates, melting and decomposing, with slight previous darkening, at 216—218°. This melting point led us to suspect that the substance was cotarnmethine methiodide, which melts at 217—219°; but a careful comparison of the two substances clearly proved that this was not the case, also, an intimate mixture of these methiodides melted at 196—200°.

On analysis of a specimen dried in a vacuum:

0.1409 gave 0.0766 AgI. I = 29.4.

$\text{C}_{15}\text{H}_{21}\text{O}_6\text{N}_2\text{I}$ requires I = 29.1 per cent.

Since in the case of anhydrocotarninenitroethane only one methiodide is isolated, it probably corresponds with the simple methiodide of anhydrocotarninenitromethane, a supposition which is in agreement with its pale yellow colour and its percentage of iodine. The constitution of the substance is probably correctly represented at the head of the section, but it is impossible to be sure of this until the products of its decomposition by alkalis are examined. A volatile base is produced in only very small quantities in this reaction.

Anhydrocotarnine-2-nitrotoluene,

A condensation can be effected between cotarnine and *o*-nitrotoluene in the absence of any condensation agent, but the process is slow, and results in a small yield of the desired product. The use of sodium ethoxide was found to have a large effect in facilitating the preparation of this substance, and the following were the conditions employed:

A solution of sodium ethoxide (0.5 gram of sodium) in alcohol (50 c.c.) was added to a mixture of cotarnine (5 grams) and *o*-nitrotoluene (10 grams), and the liquid was then kept in the cold for twenty-four hours. The yellow solution was then treated with dilute hydrochloric acid, and extracted with ether to remove the excess of nitrotoluene. The aqueous layer was separated, and, after saturating with sodium acetate, again extracted with ether. In this way the condensation product is separated from cotarnine, because the latter is not liberated from its salts by sodium acetate.

The pale yellow ethereal solution was washed with water, dried with potassium carbonate, and distilled, leaving a viscid, yellow oil, which could not be induced to crystallise. It was dissolved in alcohol, and treated with a solution of picric acid in the same solvent, when after a short time a very sparingly soluble picrate crystallised from the solution in intense yellow prisms. The substance so obtained was quite pure, as the following analysis indicates, and very little is to be gained by the crystallisation of this picrate, since the only solvent in which it is sufficiently soluble for the purpose is acetic acid, and a certain amount of decomposition ensues. A specimen of this derivative was later prepared from the pure base, and found to melt at 203–205°:

0.1275 gave 12.7 c.c. N_2 at 14° and 752 mm. $\text{N}=11.5$.

$\text{C}_{24}\text{H}_{21}\text{O}_{12}\text{N}_5$ requires $\text{N}=11.9$ per cent.

The picrate was then decomposed by very dilute sodium hydroxide, whilst the base produced was simultaneously extracted with ether. This process was accomplished in a very much shorter time when the alkali was repeatedly changed. In any case, the picrate is difficult to decompose, especially by ammonia or potassium hydroxide.

The ethereal solution of anhydrocotarnine-2-nitrotoluene was washed with water, dried with potassium carbonate, and distilled. The residue now became solid on scratching the sides of the containing vessel, and the substance was twice recrystallised from not too much methyl alcohol. It was so obtained in pale yellow prisms, melting at 75°.

On analysis of a specimen dried in a vacuum over sulphuric acid 0.1235 gave 0.2891 CO₂ and 0.0650 H₂O. C=63.8; H=5.8.

C₁₉H₂₀O₃N₂ requires C=64.0; H=5.6 per cent.

This compound is readily soluble in ethyl alcohol or ether, sparingly so in methyl alcohol or light petroleum; from a hot solution in the latter solvent it is deposited in flat prisms, which are all but colourless.

The hydrochloride is sparingly soluble in water, and crystallises in perfectly colourless micro-prisms of rather indefinite shape, when the solution of the base in concentrated hydrochloric acid is diluted. The double salts, for example, the platinichloride, aurichloride, and mercurichloride, are very sparingly soluble amorphous precipitates. The substance dissolves readily in dilute sulphuric acid, but the sulphate soon crystallises from the solution, and consists of colourless, rectangular prisms.

When a warm solution of the hydrochloride is treated with zinc, reduction readily occurs, and the pale yellow liquid resulting on the addition of sodium nitrite contains a diazonium salt, which yields intense red azo-dyes with β -naphthol and "R-salt" in alkaline solution.

It is of interest to note that this base is not decomposed by boiling with acetic acid, and in this respect it differs from the dinitro-derivatives shortly to be described.

The experience gained in dealing with the foregoing substance was applied in condensing cotarnine with *p*-nitrotoluene, since it was found that the reaction was impracticably slow without a condensing agent.

A mixture of cotarnine (10 grams), *p*-nitrotoluene (15 grams), and alcohol (100 c.c. containing sodium ethoxide from 1 gram of sodium) was gently warmed until a clear solution was obtained, and then allowed to remain without further heating for a day. The liquid was diluted with water, acidified with hydrochloric acid, and

parated by filtration from the unchanged *p*-nitrotoluene. The addition of ammonia to the filtrate produced a milky solution, from which a quantity of a crystalline substance gradually separated. This was collected, and crystallised, first from methyl, and then from ethyl alcohol.

On analysis of a specimen dried in a vacuum over sulphuric acid: 0.1331 gave 0.3138 CO₂ and 0.0711 H₂O. C=64.3; H=5.9.

C₁₀H₁₀O₂N₂ requires C=64.0; H=5.6 per cent.

Anhydrocotarnine-4-nitrotoluene is readily soluble in boiling ethyl alcohol, but sparingly so in the cold, and separates in aggregates of leaf-shaped crystals. It melts at 121–122°, without decomposition. Although it is a pale yellow substance, it forms colourless salts, of which the hydrochloride and sulphate are sparingly soluble in water, the former crystallising from a hot aqueous solution in glistening, elongated prisms. The platinichloride is an amorphous precipitate, which changes to yellow needles on boiling the solution. A picrate very sparingly soluble in alcohol is produced in canary-yellow prisms when picric acid is added to a hot alcoholic solution of the base. This derivative melts at 188–190°.

The observations on the stability in boiling acetic acid and on the formation of azo-dyes that were made with anhydrocotarnine-2-nitrotoluene (see above), apply also to anhydrocotarnine-4-nitrotoluene.

Methyl Anhydrocotarnine-o-nitro-p-toluate,

Methyl *o*-nitro-*p*-toluate is mentioned by Noad (*Annalen*, 1847, 53, 297), who describes it as a crystalline substance. We have prepared it by boiling *o*-nitro-*p*-toluic acid with 5 per cent. methyl-alcoholic sulphuric acid for half an hour. The ester crystallises well from methyl alcohol in long, colourless needles, and melts sharply at 31°:

0.1130 gave 0.2282 CO₂ and 0.0478 H₂O. C=55.1; H=4.7.

C₉H₈O₄N requires C=55.4; H=4.6 per cent.

Although it is a mononitrotoluene derivative, the negative effect of the carbomethoxy-group is so great that the condensation with cotarnine can be accomplished without the use of sodium ethoxide. In carrying out this reaction a solution of methyl *o*-nitro-*p*-toluate (10 grams) and cotarnine (10 grams) in methyl alcohol (65 c.c.) was boiled for three hours. The solution was then cooled, and allowed to remain in the ice-chest overnight. The substance gradually crystallised from the yellowish-brown liquid, and very

little of the base remained in the mother liquor. It was collected, washed with methyl alcohol, dried, and crystallised by adding methyl alcohol, in which it is very sparingly soluble, to its saturated solution in boiling methyl ethyl ketone. Almost colourless, prismatic crystals were obtained, and after recrystallisation melted at 146°.

0.1500 gave 0.3360 CO₂ and 0.0741 H₂O. C = 61.1; H = 5.5.

C₂₁H₂₇O₇N₂ requires C = 60.9; H = 5.3 per cent.

The substance yields readily soluble salts with mineral acids, and the usual not very characteristic, sparingly soluble double salts. It is not changed on boiling with glacial acetic acid for a short time. The picrate is obtained in canary-yellow prisms, melting at 163—170°, by adding a methyl-alcoholic solution of picric acid to solution of the base in methyl ethyl ketone.

When the base is boiled with alcoholic potassium hydroxide it gradually dissolves, and is not reprecipitated on the addition of water. That the ester has been hydrolysed in a normal manner is proved by the fact that on the addition of hydrochloric acid and aqueous picric acid to the solution a bright yellow picrate is precipitated. This can be recrystallised from a large quantity of a mixture of equal parts of acetone and methyl alcohol, and occurs in microscopic prisms, melting at 183—185°. Its formulation as anhydrocotarnine-*o*-nitro-*p*-toluic acid picrate is justified by its immediate and complete solubility in sodium carbonate, and by the conversion into methyl anhydrocotarnine-*o*-nitro-*p*-toluate picrate, a change which can be effected by the agency of a solution of picric acid in methyl-alcoholic hydrochloric acid. The melting point of the picrate falls to 168° with slight previous softening, it is no longer soluble in sodium carbonate, and on treatment with alkali and ether is decomposed, so that the original ester base can be recovered from the ethereal solution.

Anhydrocotarnine-2:6-dinitrotoluene,

A solution of 2:6-dinitrotoluene (3.6 grams) in as little methyl alcohol as possible was added to cotarnine (4.8 grams) and methyl alcohol (30 c.c.), and the mixture boiled for five minutes. After some time the deep brownish-red solution began to deposit a crystalline substance. In subsequent operations this separation was very much facilitated by seeding. The crystals were collected, washed with methyl alcohol, and recrystallised from ethyl alcohol. The methyl-alcoholic mother liquor and washings contain a further

quantity of the substance, which can be obtained by the partial evaporation of the solvent. The new substance crystallises from ethyl alcohol in bright yellow prisms, melting at 112—114°.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1347 gave 0.2824 CO_2 and 0.0578 H_2O . $\text{C}=57.2$; $\text{H}=4.8$.

$\text{C}_{15}\text{H}_{19}\text{O}_7\text{N}_3$ requires $\text{C}=56.8$, $\text{H}=4.7$ per cent.

The substance is readily soluble in boiling ethyl alcohol and in chloroform or benzene. When boiled with acetic acid, the colourless solution becomes yellow, and 2:6-dinitrotoluene (m. p. 80°) and cotarnine acetate are produced.

The *picrate* is obtained by mixing a solution of the base in methyl ethyl ketone with an alcoholic solution of picric acid. It is sparingly soluble in most solvents, and forms canary-yellow prisms, melting at 153—155°.

Methiodide.—The base was boiled with an excess of methyl iodide for ten minutes, when a methiodide was produced, which crystallised from methyl alcohol in light yellow prisms, melting at 210—212°. Although the substance had all the characteristics of a pure compound, and its melting point was not raised by further crystallisation, yet, as the following results show, the percentage of iodine found was always high:

0.1390 gave 0.0627 AgI . $\text{I}=24.4$.

0.1215 „ 0.0562 AgI . $\text{I}=25.0$.

$\text{C}_{20}\text{H}_{22}\text{O}_7\text{N}_3\text{I}$ requires $\text{I}=23.4$ per cent.

We are unable to suggest any explanation of this anomaly, since we regard the constitution of the substance as proved by its decomposition with alkalis, as described in the next section.

2':6'-Dinitro-2-methoxy-3:4-methylenedioxy-6- β -dimethylamino-

Anhydrocotarnine-2:6-dinitrotoluene methiodide was dissolved in water, and heated on the steam-bath with an excess of freshly precipitated silver chloride during a quarter of an hour. Silver iodide was produced, and the solution of the methochloride was collected and treated with excess of sodium hydroxide. After gently warming for a few minutes, the copious, brown precipitate which was formed was collected, washed, dried, and crystallised from methyl alcohol.

When prepared in this way the substance has a brilliant, orange-red colour, and occurs in lozenge-shaped plates, melting at 93—95°.

but occasionally yellow crystals melting at 75° were obtained, these contained solvent of crystallisation, and on remaining overnight in the air, reverted to the red variety, and melted at 94° .

On analysis of a specimen dried in a vacuum over sulphuric acid,

0.1200 gave 0.2568 CO_2 and 0.0551 H_2O . $\text{C}=58.3$; $\text{H}=5.1$;

$\text{C}_{20}\text{H}_{21}\text{O}_7\text{N}_3$ requires $\text{C}=57.8$; $\text{H}=5.0$ per cent.

Considerable care was necessary in carrying out the combustion, as the compound tends to decompose with violence.

This substance is a base entirely analogous to the corresponding compound from 2:4-dinitrotoluene. It is sparingly soluble in methyl alcohol, but readily soluble in ethyl acetate or benzene. The hydrochloride is sparingly soluble in water or cold alcohol, readily in boiling alcohol, and on the addition of picric acid to the solution a crystalline picrate is obtained.

Anhydrocotarnine-2:4-dinitrotoluene,

This substance was prepared in a manner exactly similar to that described in the case of the 2:6-isomeride (see above), but it was obtained with greater readiness, and in practically quantitative yield.

When equimolecular quantities of cotarnine and 2:4-dinitrotoluene were boiled together in methyl-alcoholic solution, separation of the yellow crystals of the condensation product usually occurred in a few minutes, and while the liquid was hot. The crystalline precipitate was separated from the cooled solution by filtration, and the substance purified by crystallisation from a mixture of chloroform and methyl alcohol. The yellow prisms so obtained melt at $145\text{--}146^{\circ}$ with vigorous decomposition.

On analysis of a specimen dried in a vacuum over sulphuric acid

0.1194 gave 0.2477 CO_2 and 0.0518 H_2O . $\text{C}=56.6$; $\text{H}=4.8$;

$\text{C}_{19}\text{H}_{19}\text{O}_7\text{N}_3$ requires $\text{C}=56.8$; $\text{H}=4.7$ per cent.

The substance is sparingly soluble in methyl or ethyl alcohol and in benzene, readily so in chloroform or pyridine. The base itself and all its derivatives are more sparingly soluble than the corresponding isomerides from 2:6-dinitrotoluene.

The solution of the compound in dilute hydrochloric acid is pale yellow, and the addition of ammonia regenerates the unchanged substance as a light yellow, amorphous precipitate, rapidly becoming crystalline. The same applies to the solution of the base in cold

acetic acid; if, however, this solution is boiled, then decomposition ensues, with production of cotarnine (picrate, m. p. 141—143°) and dinitrotoluene (m. p. 69°). This decomposition is discussed in the introduction to the paper.

Precipitates of double salts are obtained when the appropriate reagents are added to a solution of the base in dilute acid, but they are not specially characteristic.

Methiodide.—This derivative was obtained by boiling the finely powdered substance with an excess of methyl iodide. The salt was quickly formed, and was found to crystallise from methyl alcohol in orange prisms. If quickly heated the substance will melt and evolve gas, even below 180°, but when the melting point is taken slowly it is found to be 244—245°, with gradual decomposition above 200°. Great difficulty was experienced in obtaining a pure specimen of this methiodide, although, as in the case of the 2:6-dinitro-compound, the external characteristics were those of a single substance:

0.1748 gave 0.0738 AgI. I = 22.8.

$C_{20}H_{22}O_7N_3I$ requires I = 23.4 per cent.

2:4'-Dinitro-2-methoxy-3:4-methylenedioxy-6-β-dimethylamino-

The methiodide of anhydrocotarnine-2:4-dinitrotoluene was converted into the methochloride by warming with silver chloride in aqueous solution, and after filtration an excess of sodium hydroxide was added. The dense, orange-coloured precipitate was collected, dried, and crystallised from ethyl acetate. It separates in long, reddish-brown prisms, melting at 155°.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1335 gave 0.2833 CO₂ and 0.0656 H₂O. C = 57.8; H = 5.4.

0.1145 „ 0.2440 CO₂ „ 0.0500 H₂O. C = 58.1; H = 4.8.

$C_{20}H_{21}O_7N_3$ requires C = 57.8; H = 5.0 per cent.

This substance is very sparingly soluble in hot methyl alcohol, but easily dissolves in boiling chloroform or ethyl acetate. The hydrochloride is very sparingly soluble in water and alcohol; it crystallises from aqueous alcohol in yellow plates. A hot aqueous-alcoholic solution of the hydrochloride on treatment with picric acid deposits lozenge-shaped crystals of a yellow picrate, which melt at 155—187°.

Hydriodide.—This derivative is of considerable interest in that the fact of its difference from the methiodide of anhydrocotarnine-2:4-dinitrotoluene proves that the latter base has a hydrocotarnine

structure. It is obtained as a yellow precipitate by mixing a solution of the base in glacial acetic acid with a dilute alcoholic solution of hydriodic acid, and the yellow crystals on boiling with alcohol are converted into brilliant red prisms. The substance was crystallised from formic acid, and separated at first as the red variety, which could be obtained in a pure condition. When, however, a certain temperature was reached, the yellow form began to crystallise in glistening flakes. It appears that the yellow form separates at low temperatures, and it can always be converted into the more stable red form by warming in the presence of any solvent in which the substance is partly soluble. The yellow crystals were not obtained free from the red; the latter melt and decompose at 245–248°, and gave the following result on analysis:

0.1166 gave 0.0498 AgI. $I = 23.1$.

$C_{20}H_{22}O_7N_3I$ requires $I = 23.4$ per cent.

Methiodide.—When the base is boiled for five minutes with methyl iodide a methiodide is produced, which is exceedingly sparingly soluble in almost all solvents. The substance was prepared in considerable quantity, and purified by extraction with boiling ethyl acetate which removed any unaltered base. For analysis a small specimen was obtained in a pure condition by crystallisation from a large quantity of methyl alcohol. It consists of orange-yellow, rectangular prisms, which melt at 244–246°:

0.1575 gave 0.0661 AgI. $I = 22.7$.

$C_{21}H_{24}O_7N_3I$ requires $I = 22.8$ per cent.

The corresponding *methochloride* was produced by heating the methiodide in aqueous suspension with freshly precipitated silver chloride. The filtered solution deposits on cooling a crystalline precipitate resembling very much lead iodide. The methochloride, although, as is usual, more soluble than the methiodide, is still sparingly soluble in water and alcohol. It is stable in the presence of alkaline hydroxides, so that it was necessary to resort to the use of silver oxide in order to obtain the quaternary ammonium base.

In the experiment which is described below, it was found to be more convenient to employ the methiodide direct.

2':4'-Dinitro-2-methoxy-3:4-methylenedioxy-6-vinylstilbene.

The methiodide described above (5 grams) was completely dissolved in the least possible quantity of hot water (5 litres), and

digested on the steam-bath with silver oxide (from 10 grams of silver nitrate) during six hours. The orange-coloured solution was filtered, and evaporated until crystallisation at the surface commenced. The solution had the odour of trimethylamine, and was filtered from a small quantity of a neutral, red substance. On cooling, a new substance crystallised in golden spangles, which under the microscope are seen to consist of irregular, hexagonal prisms. On heating, the compound turns red at $120-130^{\circ}$, and then decomposes at $164-166^{\circ}$. Its whole behaviour harmonises with the view that it is a methyl hydroxide, and one which evidently possesses considerable stability. It dissolves in hot water, and the yellow solution gives a precipitate of the characteristic methochloride with hydrochloric acid. The stability of this ammonium base is remarkable, and we experienced great difficulty in causing its fission into trimethylamine and the neutral stilbene derivative. This could be accomplished, at the expense of great loss through decomposition, by heating the substance in the dry state. The method finally adopted was to boil a concentrated aqueous solution for many hours, when a slow decomposition occurred, involving the production of trimethylamine and a red powder, which was separated by filtration. The substance was purified by boiling with water to remove a small quantity of unaltered methyl hydroxide, and, after drying, crystallised from acetone. The crystals are tiny, rectangular prisms, melting at $162-163^{\circ}$. When first obtained they are brownish-yellow, but on drying at 90° they become deep, brilliant red. The substance is quite devoid of basic properties, and crystallises unchanged from acetic acid. It is fairly soluble in hot acetone, and sparingly so in alcohol.

On analysis of a specimen dried at 90° :

0.1173 gave 0.2535 CO_2 and 0.0441 H_2O . $\text{C}=58.9$; $\text{H}=4.2$.

$\text{C}_{18}\text{H}_{14}\text{O}_7\text{N}_2$ requires $\text{C}=58.4$; $\text{H}=3.8$ per cent.

In order to be quite sure of the constitution of this neutral substance, its synthesis was accomplished by the following process:

Cotarnone (2 grams) and 2:4-dinitrotoluene (2 grams) were melted together, and warmed on the water-bath for an hour with three drops of piperidine. The mass of red crystals which resulted was dissolved in boiling acetic acid, and on cooling the substance separated in aggregates of micro-prisms, resembling chromic acid in appearance. The substance melted, after recrystallisation, at $163-164^{\circ}$, and its melting point was unaltered by admixture with the substance obtained as above from anhydrocotarninedinitrotoluene:

0.1409 gave 0.3040 CO_2 and 0.0497 H_2O . $\text{C}=58.8$; $\text{H}=3.9$ per cent.

This substance was prepared by the condensation of methyl dinitrophenylacetate (Borsche, *Ber.*, 1909, **42**, 1310) with cotarnine under the following conditions. A mixture of the ester (2 grams) and an equal quantity of cotarnine was boiled for five minutes with enough methyl alcohol to dissolve it. The solution acquires a deep black colour, and on cooling deposits jet black crystals, which were collected and dried. The substance was recrystallised from methyl alcohol, and obtained in black prisms, which show green iridescence and melt at $150\text{--}151^\circ$ with vigorous decomposition.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1310 gave 0.2649 CO_2 and 0.0561 H_2O . $\text{C}=55.1$; $\text{H}=4.7$.

$\text{C}_{21}\text{H}_{21}\text{O}_9\text{N}_3$ requires $\text{C}=54.9$; $\text{H}=4.5$ per cent.

The black colour of this substance, which is so characteristic, is only observed in the crystalline condition; when rubbed on paper, a brown streak is produced, and cold methyl alcohol is coloured red by contact with the solid. No stable salts could be prepared, since in contact with strong or dilute acids it is at once decomposed with production of cotarnine and of methyl dinitrophenylacetate (m. p. 82°). Further, as seen below, no methiodide could be obtained. It is in consideration of these facts, which clearly show its lack of resemblance to anhydrocotarnine-2:4-dinitrotoluene, that we have assigned the open-chain structure, figured above, to this substance.

Action of Methyl Iodide.—The black condensation product was boiled for an hour with an excess of methyl alcohol and methyl iodide. On cooling, a quantity of reddish-brown crystals were obtained, and these were collected, drained on porous porcelain, and recrystallised from methyl alcohol. The faintly yellow crystals were examined under the microscope, and found to consist of hexagonal plates, and no crystals of other shape could be detected. The melting point was $210\text{--}213^\circ$ (decomp.), and was unaltered by the recrystallisation of the substance. It is evidently a pure compound, but we have been unable to identify it. The percentage of iodine found was 35.5, which is much too high for the normal methiodide (21.1), and agrees better for a substance like hydrocotarnine methiodide or hydriodide. These compounds were prepared in order to effect a direct comparison, but the result showed that the unidentified methiodide was a different substance.

Hydrocotarnine Hydriodide.—This salt was prepared by the addition of concentrated aqueous hydriodic acid to a solution of

hydrocotarnine in alcohol. The substance crystallises from methyl alcohol in colourless needles, melting at 195—196°.

Hydrocotarnine Methiodide.—Hydrocotarnine reacts with methyl iodide in the cold, and the product crystallises well from methyl alcohol in magnificent prisms. This derivative melts without decomposition at 206—207°.

On analysis of a specimen dried in a vacuum:

0.1009 gave 0.0650 AgI. $I=34.8$.

$C_{15}H_{18}O_3NI$ requires $I=35.0$ per cent.

Cotarnine condenses with trinitrotoluene as readily as with nitromethane, and the preparation of the condensation product is a very simple matter, and merely consists in grinding up trinitrotoluene with an alcoholic solution of an equimolecular quantity of cotarnine. As soon as the substances come into contact, the orange-yellow compound commences to crystallise, and the reaction is complete in a few minutes. The crystals are collected, and dissolved in cold chloroform, and, on adding methyl alcohol to the solution, the new compound is obtained in a pure condition as intense yellow prisms, melting, when slowly heated, at 130° with explosive decomposition. This property rendered the analysis of the substance a matter of some difficulty, and high results were obtained, both for carbon and hydrogen. This could scarcely be avoided, since even when the substance was mixed with a large excess of copper oxide an explosion occurred, and nitrous fumes could be seen if the bulbs.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1224 gave 0.2321 CO_2 and 0.0517 H_2O . $C=51.7$; $H=4.7$.

$C_{19}H_{18}O_6N_4$ requires $C=51.1$; $H=4.0$ per cent.

The substance is sparingly soluble in most neutral solvents, but readily dissolves in cold chloroform, giving a brownish-yellow solution. The solutions in hot alcohol or ethyl acetate are, however, intensely red, and this property is so characteristic that although the trinitro-compound is practically insoluble, yet alcohol is coloured red by contact with it in the cold.

The base dissolves in concentrated hydrochloric acid, forming a pale yellow solution, which remains clear on dilution with water; on keeping, however, long, yellow needles of the hydrochloride crystallise out, and may be recrystallised from warm dilute hydrochloric acid. If the solution of the hydrochloride is boiled, trinitrotoluene is obtained, but the process is not a smooth one. When

the pale yellow solution of the base in glacial acetic acid is boiled, a complete decomposition ensues, with the production of trinitro-toluene and cotarnine. The former crystallised from the acetic acid solution in needles melting at 81° , whilst the latter was obtained in the form of its picrate (m. p. $141-143^{\circ}$) when the diluted and filtered mother liquor from this crystallisation was treated with picric acid.

Dianhydroticotarnine-2:4:6-trinitro-m-xylene,

Cotarnine was condensed with trinitro-*m*-xylene under the following conditions: Finely powdered trinitro-*m*-xylene (10 grams) was boiled with methyl alcohol (300 c.c.) sufficiently long to dissolve the greatest possible amount of the substance, and then treated with cotarnine (20 grams) and boiled for a further ten minutes. The trinitro-compound gradually passed into solution, and when the brownish-red liquid was allowed to remain in the cold a quantity of crystals separated. These were collected and recrystallised from ethyl acetate, and then again by adding methyl alcohol to the solution of the substance in a little cold chloroform. Pale yellow prisms of rather indefinite shape were obtained. The substance melts at $153-154^{\circ}$ with vigorous decomposition and slight previous darkening.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1270 gave 0.2660 CO_2 and 0.0630 H_2O . $\text{C}=57.1$; $\text{H}=5.5$

$\text{C}_{32}\text{H}_{33}\text{O}_{12}\text{N}_3$ requires $\text{C}=56.5$; $\text{H}=5.0$ per cent.

The rather high results that were obtained in this analysis do militate against the conclusions we have drawn with respect to its composition, since they were certainly due to the same cause as in the case of the substance from trinitrotoluene. The substance closely resembles the compound produced by the condensation of trinitromesitylene and cotarnine, which from an analytical point of view was very carefully investigated (see p. 2135).

Dianhydroticotarnine-trinitro-m-xylene is a base readily soluble in dilute acids, but does not form any very characteristic derivatives. The platinichloride and aurichloride are amorphous precipitates. When the almost colourless solution of the base in glacial acetic acid is boiled, it acquires a yellow colour, and, on cooling, colourless prisms of trinitroxylene separate. The filtrate from these crystals (which melted at 182°) gives on dilution and treatment with picric acid a yellow precipitate of a picrate, which crystallises from alcohol or water in silky needles, melting at $139-143^{\circ}$, and obviously consists of the picrate of cotarnine.

Dianhydrotarninetritromesitylene,

In order to effect a condensation between cotarnine and trinitromesitylene, it is not sufficient to boil an alcoholic solution of these substances on the steam-bath; much more vigorous treatment is necessary. The reaction was carried out as follows:

Tritromesitylene (1.5 grams) was added to a solution of cotarnine (2 grams) in methyl alcohol (10 c.c.). The mixture was boiled as vigorously as possible in a test tube, and continuously stirred with a glass rod, while the alcohol was allowed to evaporate. The trinitro-compound gradually dissolved, and a stage was reached at which the whole of it had passed into solution. The boiling was continued for one or two minutes longer, and the liquid was then poured into cold water. A pale yellow solid, at first rather viscid, was precipitated. Several such experiments were carried out, and the combined products separated by filtration and treated with dilute hydrochloric acid, which dissolved the greater part of the solid, forming a soluble salt, and leaving undissolved a small quantity of trinitromesitylene, which was removed by filtration. The yellow solution was rendered alkaline with ammonia, and the crude precipitated base was separated, washed, dried, and crystallised from a mixture of acetone and methyl alcohol. After four crystallisations the substance was obtained in pale yellow, prismatic crystals, melting at 183–185°. This crystallisation is very wasteful, and most of the analyses were made of specimens having rather lower melting point; indeed, the slightly impure substance melts so sharply at 175–176° that we had at first assigned this melting point to the compound.

On analyses of specimens dried in a vacuum over sulphuric acid:

- A. 0.1429 gave 0.2993 CO₂ and 0.0695 H₂O. C=57.1; H=5.4.
 - B. 0.1273 „ 0.2635 CO₂ „ 0.0640 H₂O. C=57.4; H=5.5.
 - C. 0.0675 „ 6.15 c.c. N₂ at 17° and 755 mm. N=10.4.
 - D. In a determination of methoxyl by Perkin's modification of Zeisel's method, 0.1910 gave 0.1211 AgI. MeO=8.4.
- C₃₃H₃₅O₁₂N₅ requires C=57.1; H=5.0; N=10.0;
MeO=8.9 per cent.

(A) melted at about 168°; (B) was recrystallised (A), and melted at 171°; (C) was the purest specimen, melting at 183–185°; (D) melted at 175–176°. This substance was also prepared, using ethyl alcohol as the solvent, in which the reaction was carried out. The product obtained was identical with that described above; it melted at 175–177°, and the melting point was not lowered when the

substance was mixed with an equal quantity of the compound produced in the reaction when methyl alcohol was employed as solvent:

0.1218 gave 0.2552 CO_2 and 0.0589 H_2O . $\text{C}=57.1$; $\text{H}=5.3$

This result of interest, inasmuch as the analytical results for the base seemed to agree fairly well with the theory that one molecule of cotarnine condenses with one of the trinitro-compound, and that one of the nitro-groups is replaced by methoxyl. That this is not the case is shown by the above experiment.

The salts of this substance are readily soluble in water, and the solutions are almost colourless. On boiling with glacial acetic acid, trinitromesitylene (m. p. 228°) was obtained, the reaction evidently being quite analogous to the similar decomposition of anhydrocotarninetrinitrotoluene.

Anhydrohydrastinininitromethane,

This substance, and also the condensation product with 2:4-dinitrotoluene, described in the next section, were prepared in order to show that hydrastinine is apparently as reactive as cotarnine towards nitro-compounds. Hydrastinine (1 gram) dissolved in methyl alcohol (5 c.c.) was treated with nitromethane (1 gram), and the solution boiled for one minute. On cooling, the substance separated in long, colourless needles, and was recrystallised from ethyl alcohol, in which it is sparingly soluble in the cold.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1220 gave 0.2567 CO_2 and 0.0650 H_2O . $\text{C}=56.9$; $\text{H}=5.9$.

$\text{C}_{12}\text{H}_{14}\text{O}_4\text{N}_2$ requires $\text{C}=57.6$; $\text{H}=5.6$ per cent.

The substance melts to a clear liquid at $121\text{--}122^\circ$. It is readily soluble in cold benzene or chloroform, less readily in ether. In contradistinction to the corresponding cotarnine compound, the hydrochloride is readily soluble in water; the dilute solution shows faint, bluish-green fluorescence. The aurichloride is an amorphous, light brown precipitate, soluble in hot alcohol, but separates in an oily condition on cooling.

An orange-yellow *picrate* separates in prismatic needles, melting at $173\text{--}174^\circ$ on mixing hot alcoholic solutions of the base and picric acid.

Hydrastinine (2 grams) and 2:4-dinitrotoluene (2 grams) were dissolved in boiling methyl alcohol (30 c.c.), and the solution boiled until the yellow, granular precipitate began to separate. After cooling, the substance was collected and recrystallised from a mixture of benzene and methyl alcohol. The yield approximated closely to that demanded by theory.

On analysis of a specimen dried in a vacuum over sulphuric acid:

0.1201 gave 0.2568 CO_2 and 0.0482 H_2O . $\text{C}=58.3$; $\text{H}=4.4$.

$\text{C}_{18}\text{H}_{17}\text{O}_2\text{N}_3$ requires $\text{C}=58.2$; $\text{H}=4.6$ per cent.

The substance crystallises in microscopic balls of needles, is pale yellow, and melts at $143\text{--}144^\circ$ with vigorous decomposition at a slightly higher temperature. It is very sparingly soluble in hot or cold alcohol, but readily so in benzene.

The *hydrochloride* is sparingly soluble in cold water, and can be crystallised from hot dilute hydrochloric acid. It forms pale yellow prisms.

The *picrate* is best prepared by mixing a hot solution of the base in methyl ethyl ketone with a solution of picric acid in the same solvent. It forms pale yellow prisms, melting at $172\text{--}173^\circ$, and is very sparingly soluble in the usual solvents.

The decomposition of this substance on boiling with acetic acid is quite similar to that of anhydrocotarnine-2:4-dinitrotoluene. The almost colourless solution of the base in glacial acetic acid acquires a yellow colour on boiling, and on dilution with water, needles, melting at 68° and consisting of dinitrotoluene, separate from the solution. The filtrate from these exhibits a strong bluish-green fluorescence showing the presence of hydrastinine.

In conclusion, we desire to thank the Research Fund Committee of the Chemical Society for a grant which has partly defrayed the expenses of this investigation.

ECK (J. J. VAN). Effect of Heat on the Peroxydase in Cow's Milk	ii, 114

INDEX OF AUTHORS' NAMES

IN TRANSACTIONS AND ABSTRACTS

A.

Abderhalden, E., i, 955, 1050.
 Abderhalden, E., M. Guggenheim,
 and P. Hirsch, i, 954.
 Abderhalden, E., and P. Hirsch,
 ii, 1119.
 Abderhalden, E., and K. Kautzsch,
 i, 954.
 Abderhalden, E., and P. Rona,
 ii, 1108.
 Abderhalden, E., and A. Weil, i, 1049.
 Abe, R., i, 940.
 Aboulenc, J. See J. B. Senderens.
 Abraham, F. See A. Michaelis.
 Ackermann, D., R. Engeland, and
 F. Kutscher, i, 956.
 Adams, J. See A. Windans.
 Agulhon, H., ii, 1140.
 Albertini, A. See H. Decker.
 Alessandri, L. See A. Angeli.
 Allen, E. T., ii, 1093.
 Amagat, E. H., ii, 1061.
 Amberg, S., and M. C. Winternitz,
 ii, 1110.
 Amosoff, W. See N. M. Kijner.
 Anderson, R. See H. Leuchs.
 Andrews, A. E., ii, 1144.
 Angeli, A., and L. Alessandri,
 i, 1045.
 Angelico, F., i, 1003, 1032.
 Anilinfarben- und Extrakt-Fab-
 riken vorm. J. R. Geigy, i, 978.
 Aoki, Y. See R. Majima.
 Applebey, M. P. See Earl of
 Berkeley.
 Archibald, E. H., and H. von
 Wartenberg, ii, 1083.
 Arnold, J. O., and A. A. Read,
 ii, 1092.
 Auer, A. H. W., ii, 1051.
 Auerbach, F., and H. Pick, ii, 1078.
 Aweers, K., F. Eisenlohr, and W. A.
 Roth, ii, 1065.

B.

Bachran, F. See A. Stuhler.
 Badische Anilin- & Soda-Fabrik,
 i, 936, 930, 1026, 1030; ii, 1088.
 Bahr, F., and O. Sackur, ii, 1091.
 Bainbridge, F. A., ii, 1121.
 Bakunin, M., and E. Lania, i, 992.
 Balbiano, L., i, 987.
 Bamberger, E., i, 996.
 Bamberger, M., and K. Krüse,
 ii, 1049.
 Bancelin, M., ii, 1067.
 Barginelli, G., and E. Martegiani,
 i, 965.
 Barger, G., and A. J. Ewins, TRANS.,
 2336.
 Barnes, E. J. See A. McWilliam.
 Bartoll, F. E., ii, 1072.
 Bary, P., and L. Weydert, i, 1003.
 Beattie, J. M., and A. G. Yates,
 ii, 1122.
 Bechtereff, P., ii, 1054.
 Becker, F., ii, 1063.
 Béchal, A., and A. Detenif, i, 957.
 Berkeley, Earl of, and M. P. Apple-
 bey, ii, 1061, 1062.
 Bernardini, L. See G. Calcagni.
 Berthelm, A., i, 1055.
 Besson, A., ii, 1082.
 Besson, A. A., ii, 1140.
 Boutell, A., ii, 1094.
 Bianchi, G., and R. Schiff, i, 977.
 Biilmann, E., i, 963.
 Biltz, W., ii, 1097.
 Biltz, W., and E. Marcus, ii, 1101.
 Blackman, P., ii, 1081.
 Blümmer, E. See W. Steinkopf.
 Blumberg, P. See O. Diels.
 Böcker, E. See K. Scholl.
 Boehringer & Söhne, C. F., i, 947,
 986, 1011.
 Böttcher, B., and S. Horowitz,
 i, 1011.

Bogert, M. T., i, 983.
 Boggs, C. R. See A. A. Noyes.
 Boismann, E., i, 957.
 Bolton, W. von, ii, 1118.
 Bongiovanni, C., ii, 1052.
 Bonnerot, S. See G. Charpy.
 Borsche, W., i, 1018.
 Bostock, G. D., ii, 1112.
 Bongault, J., and C. Charaux, i, 949.
 Bourbon, A. See É. Vigouroux.
 Bourgeois, E., and A. Fonessein, i, 963.
 Bourgeois, E., and P. Huber, i, 964.
 Bourquelot, E., and M. Bridel, i, 1053.
 Boutaric, A., ii, 1060.
 Bowser, L. T., ii, 1135.
 Boycott, A. E., ii, 1108.
 Boycott, A. E., and K. A. Chisolm, ii, 1107.
 Boyd, R. See G. G. Henderson.
 Braun, J. von, and H. Deutsch, i, 938.
 Braun, J. von, H. Deutsch, and O. Krnber, i, 968.
 Bray, W. C., ii, 1075.
 Bray, W. C., and W. J. Winninghoff, ii, 1075.
 Bray, W. C. See also A. A. Noyes.
 Bressanin, G., ii, 1133, 1134.
 Bridel, M. See E. Bourquelot.
 Brodtkorb, T. See H. Ost.
 Brodzewski, W., and L. Heckspill, ii, 1055.
 Brooks, B. T., i, 1000.
 Browne, A. W., and A. E. Houlehan, ii, 1085.
 Browne, A. W., and T. W. B. Welsh, ii, 1084.
 Browning, C. H., and J. Cruickshank, ii, 1118.
 Brunck, O., ii, 1136.
 Bülow, C., and H. Güller, i, 1043.
 Buglia, G., ii, 1113.
 Buraczewski, J., L. Krauze, and A. Krzemiecki, i, 1052.
 Burmann, J., ii, 1125.
 Burri, R., and H. Schmid, ii, 1115.
 Butavand, F., ii, 1046.
 Byers, H. G., and A. F. Morgan, ii, 1057.

C.

Caccia, P. See A. Patta.
 Calcagni, G., and L. Bernardini, ii, 1078.
 Carpenter, H. C. H., ii, 1091.
 Carter, H., ii, 1046.
 Cassella & Co., L., i, 1025.

Cavaazi, A., ii, 1137.
 Ceccarelli, O. See M. Levi-Maltrass.
 Cermak, P., and H. Schmidt, ii, 1046.
 Chablay, E., i, 939.
 Chacón, A., ii, 1080.
 Charanz, C. See J. Bonganlt.
 Charpy, G., and S. Bonnarot, ii, 1091.
 Cherrier, G., and G. Ferreri, i, 1046.
 Chattaway, F. D., and D. P. f. Wunsch, TRANA, 2258.
 Chemische Fabrik vorm. Sandoz, i, 1047.
 Chisolm, R. A., ii, 1107, 1108.
 Chisolm, R. A. See also A. E. Boycott.
 Cinsa, R., and G. Scagliarini, i, 1014.
 Claude, G., ii, 1084, 1087.
 Cobb, J. W., ii, 1092.
 Colacchi, U., i, 1030.
 Coleon, A., ii, 1068, 1071, 1066.
 Colver-Glanert, E., and S. Hilpert, ii, 1067.
 Combes, B., ii, 1125.
 Cooke, R. A., and E. E. Gorslin, ii, 1140.
 Corridi, L., ii, 1088.
 Couturier, F., i, 989.
 Crémien, V. See J. Danne.
 Crosely, A. W., and G. F. Morrell, TRANA, 2345.
 Crossley, A. W., and (Miss) G. H. Wren, TRANA, 2341.
 Croze, F., ii, 1041.
 Cruickshank, J. See C. H. Browning.
 Cummins, S. L., ii, 1123.
 Curie, (Mme.) M., ii, 1047.
 Cusmano, G. See G. Odde.

D.

Daniel-Brunet, A., and C. Rolland, ii, 1111.
 Danne, J., and V. Crémien, ii, 1042.
 Darzens, G., and H. Rost, i, 988.
 David, W. T., ii, 1048.
 Davideohn, H. See L. Michaelis.
 Decker, H., A. Albertini, A. Kaufmann, S. Pfeifer, N. Prohaska, M. Saan, and W. Wislowski, i, 1023.
 Delacro, M., i, 939.
 Delépine, M., i, 944; ii, 1061.
 Desgrez, A., ii, 1119.
 Detouf, A. See A. Béhal.
 Deutsch, H. See J. von Braun.
 Diamars, V., ii, 1110, 1117.
 Dieckmann, T. See S. Hilpert.
 Diels, O., and P. Blumberg, i, 971.
 Diels, O., and P. Fritzsche, i, 957.
 Diels, O., and R. Gollmann, i, 955.

Diawiddie, J. G., and J. H. Kastle,
i, 962.
Ditto, R. C. See O. W. Richardson.
Dixon, H. R. *TRANS.*, 2253.
Döppmann, F. See A. Michaelis.
Donaldson, H., ii, 1042.
Doroscchewsky, A. G., ii, 1062.
Doutteau, R., i, 973.
Douris, R., i, 949.
Dowgelewitsch, N. See W. N.
Ipatieff.
Durrachnabel, K. See H. Weil.
Dunlap, F. L., and L. O. Gilbert,
i, 1054.
Duparc, L., R. Sabot, and M.
Wunder, ii, 1105.
Dutoit, P., and G. von Weisses,
ii, 1129, 1130, 1137.
Duval, H., ii, 1041.

E.

Easterfield, T. H., and (Miss) C. M.
Taylor, *TRANS.*, 2298.
Ebler, E., and M. Fellner, ii, 1049.
Eck, J. J. van, ii, 1144.
Egorova, (Mlle.) V. I., i, 959.
Ehrlich, F., ii, 1122.
Ehrwein, R. See T. Klobb.
Eisenlohr, F. See K. Auwers.
Elliot, T. G., ii, 1131.
Engelard, R. See D. Ackermann.
Engelhardt, A. See W. Traube.
Engemann, K., ii, 1094.
Euklaer, J. E., ii, 1071.
Euler, H. von, i, 1051.
Euler, H. von, and A. Fodor, i, 950.
Euler, H. von, and S. Kullberg,
i, 1051.
Evans, W. L., and E. J. Witzemann,
i, 987.
Evins, A. J. See G. Barger.

F.

Farbenfabriken vorm. F. Bayer &
Co., i, 995, 1003, 1015, 1026, 1056.
Farbwerke vorm. Meister, Lucius
& Brünning, i, 995, 1055, 1056.
Farrell, F. S. See A. A. Noyes.
Fellner, M. See E. Ebler.
Ferrer, G. See G. Charrier.
Feyta, (Mlle.) E., ii, 1058.
Filippi, D., ii, 1120.
Fie, M. E. See T. B. Mendel.
Fischer, E., and D. D. van Slyke,
i, 1020.
Fischer, F., E. Stecher, and C.
Thiele, ii, 1129.

Fiacher, F., and M. Wolf, ii, 1082.
Fiacher, Hans, and F. Meyer, i, 1005.
Fiacher, Hans, and F. Meyer-Betz,
i, 1004.
Fischer, Hermann. See L. Knorr.
Flury, F., ii, 1119.
Foa, I. See F. Marino-Zuco.
Fodor, A. See H. von Euler.
Ford, W. E., ii, 1102, 1104.
Fouard, E., ii, 1071.
Fonassin, A. See E. Bourgeois.
Francesconi, L., and P. Scaraffa,
i, 1001.
Francesconi, L., and E. Sernaggiotti,
i, 1000.
Franck, H. H. See A. Skita.
Frankland, P. F., and H. H.
O'Sullivan, *TRANS.*, 2325.
Franklin, E. C., ii, 1052.
Franzen, H., and O. Steppuhn,
ii, 1122.
Fred, E. B., ii, 1123.
Friedenhangen, K., ii, 1043.
Friedlander, P., and S. Kielbasinski,
i, 1021.
Friesse, W., ii, 1142.
Fritzsche, P. See O. Diels.

G.

Gabriel, S., i, 982, 991.
Gadamer, J., and F. Kuntze, i, 1011,
1012.
Gammeltöft, S. A., ii, 1115.
Garnier, J. See T. Klobb.
Gastaldi, C., i, 1047.
Gaucher, L., ii, 1109.
Gautrelet, J., ii, 1107.
Gay, L., ii, 1058.
Geiger, W. See H. Leuchs.
Georgievics, G. von, and A. Pollak,
ii, 1070.
Gilbert, L. O. See F. L. Dunlap.
Giuganino, L. See F. Marino-Zuco.
Goebel, J. B., ii, 1078.
Goecke, O., ii, 1053.
Güller, H. See C. Bülow.
Gollmann, R. See O. Diels.
Golodtz, A., ii, 1064.
Gontermann, W., ii, 1091.
Gorelin, E. E. See R. A. Cooke.
Green, H. H., ii, 1135.
Gripenberg, W. S., ii, 1045.
Grossmann, H., and G. Jäger, i, 944.
Günther, A. See A. Michaelis.
Guggenheim, M. See E. Abder-
halden.
Guthier, A., ii, 1098.
Guye, P. A., ii, 1067.
Guyot, J., ii, 1053.

H.

- Haber, F., and J. Zawadzki, ii, 1053.
 Hackspill, L. See W. Broniewski.
 Haden, R. L. See J. H. Kastle.
 Halenka, A., and M. Kling, ii, 1131.
 Hall, O., i, 1021.
 Hardman, K. T., and A. Lapworth, TRANS., 2242.
 Hatfield, W. H., ii, 1092.
 Hatschek, E., ii, 1064.
 Hadden, W. P., ii, 1106.
 Hebert, A., ii, 1126.
 Heerdt, W. See H. Weil.
 Hemmelmayr, F. von, i, 983.
 Henderson, G. G., and R. Boyd, TRANS., 2159.
 Hertwig, O., ii, 1118.
 Herwerden, (Fraulein) H. A. van, and W. E. Ringer, ii, 1109.
 Herzog, R. O., i, 1052.
 Hess, K. See L. Knorr.
 Hilpert, S., and T. Dieckmann, ii, 1090.
 Hilpert, S. See also E. Colver-Glauret.
 Hinrichs, G. O., ii, 1080.
 Hirsch, P. See E. Abderhalden.
 Hock, H. See K. A. Hofmann.
 Hodges, E. H., ii, 1084.
 Hofmann, K. A., and H. Hock, i, 1047.
 Holle, H. See A. Reissert.
 Horowitz, S. See R. Bottcher.
 Houlehan, A. E. See A. W. Browne.
 Huber, P. See E. Bourgeois.
 Hudig, J., and H. Weit, ii, 1128.
 Hunter, A. See S. Simpson.

I.

- Ibbotson, F., ii, 1139.
 Inouye, K. See T. Svedberg.
 Ipatieff, W. N., i, 937.
 Ipatieff, W. N., and N. Dowgiewitsch, i, 937.
 Isert, F. See A. Michaelis.

J.

- Jacoby, C., ii, 1120.
 Jacoby, C., and C. Roemer, ii, 1120.
 Jäger, C., i, 1027.
 Jäger, C. See H. Grossmann.
 Janecko, E., ii, 1089.
 Jahn, F., ii, 1138.
 Jalander, Y. W., i, 1053.
 Jannschke, H., and L. Pollak, ii, 1120.
 Johnson, T. B. See H. L. Wheeler.
 Jolles, A., i, 951.
 Joly, J., and L. B. Smyth, ii, 1048.

 Jorrißen, A., ii, 1144.
 Juschtschenko, A. J., ii, 1112.

K.

- Kailan, A., i, 939.
 Kalle & Co., i, 1009.
 Kastle, J. H., and R. L. Haden, i, 974.
 Kastle, J. H. See also J. G. De-widdie.
 Kaufmann, A. See H. Decker.
 Kautzsch, K. See E. Abderhalden.
 Kehrman, F., and L. Lowry, i, 1012.
 Kehrman, F., and J. Steinberg, i, 1034.
 Keiser, E. H., and J. J. Keiser, i, 949.
 Keiser, E. H., and L. McMaster, i, 949.
 Keller, H. F., ii, 1104.
 Keller, O., i, 1014.
 Kessler, J. J. See E. H. Keiser.
 Kielbasinski, S. See P. Friedlander.
 Kiesel, A., ii, 1124.
 Kijner, N. M., i, 989, 996, 1027.
 Kijner, N. M., W. Amosoff, and Voznesensky, i, 968.
 Kijner, N. M., and A. Zavadsky, i, 1028.
 Kirmreuther, H., i, 1098.
 Klein, D., ii, 1143.
 Klemensiewicz, Z., ii, 1050.
 Kling, M. See A. Halenka.
 Klobb, T., R. Ehrwein, and J. Garnier, i, 972.
 Klotz, O., and M. F. Mann, ii, 1112.
 Knecht, E. See F. Ullmann.
 Knöpfer, G., i, 1033.
 Knorr, L., and H. Fischer, i, 976.
 Knorr, L., and K. Hess, i, 1019.
 Knorr, L., and P. Roth, i, 1014.
 Knorr, L., and H. Schubert, i, 977.
 Kobayashi, M., ii, 1089.
 Kober, P. A., and J. T. March, i, 984.
 Koch, A., ii, 1124.
 Koch, E. See K. Lendrich.
 Koenig, W., ii, 1143.
 Kohler, E. P., i, 984.
 Kohnstamm, P., and J. C. Reulen, ii, 1077.
 Kojo, K., ii, 1110.
 Komp, R., ii, 1041.
 Kondakoff, I. L., i, 998.
 Kondakoff, I. L., and I. Schindler, i, 998.
 Konjinkoff-Dobrynia, P. See I. Sementsoff.

Konstantinoff, N. S., and W. A. Smirnoff, ii, 1096.

Kowarski, S. See O. Kym.

Krause, R. A., ii, 1116.

Krause, L., i, 1016.

Krause, L. See J. Buraczewski.

Kretzl, A., and E. Lenk, ii, 1114.

Krebniewicz, Z., ii, 1050.

Kroll. See E. Rupp.

Kunber, O. See J. von Brand.

Kruse, K. See M. Bamberger.

Kryst, H. R., i, 975.

Kucmecki, A. See J. Buraczewski.

Kulberg, S. See H. von Euler.

Kunkell, F., i, 990.

Kuntze, F. See J. Gadamer.

Kuntzoff, S. D., ii, 1104.

Kutscher, F. See D. Ackermann.

Kym, O., and S. Kowarski, i, 1044.

L.

Lachs, H., and L. Michaelis, ii, 1069.

Landaw, P. P., ii, 1120.

Landauer, P. See H. Weil.

Landy, M., i, 1009.

Lauri, E. See M. Bakuin.

Lapworth, A. See R. T. Hardman.

Larson, E. S., jun., and W. T. Schaller, ii, 1102.

Lebedeff, A. von, ii, 1122.

Lebedeff, S. V., and (Mlle.) N. A. Skavronskaja, i, 959.

Leidrich, K., E. Koch, and L. Schwarz, ii, 1125.

Lenk, E. See A. Kreidl.

Lesko, J. See R. Scholl.

Lespe, A. See C. Moureu.

Lethe, (Miss) M. S., ii, 1048.

Lesser, R., i, 994.

Leuchs, H., and R. Anderson, i, 1014.

Leuchs, H., and W. Geiger, i, 1018.

Levi-Malvano, M., and O. Ceccarelli, ii, 1088, 1089.

Levy, W., N., ii, 1130.

Levy, W. C. M. See A. Roshdestwensky.

Lezio, G., ii, 1101.

Leidemann, F. A. See W. Nernst.

Leidner, B. A. See W. J. Vernadsky.

Leidner, D. E., ii, 1115.

Leidner, J., and H. Wasteneys, ii, 1110.

Leig, W. J., ii, 1121.

Leimann, A., ii, 1081.

Leig, F. S., TRANS., 2164.

Leigmann, P., ii, 1089.

Leig, W. H., ii, 1139.

Leig, L. See F. Kehrman.

Leig, A. de. See F. Reverdin.

M.

McCrae, J., ii, 1142.

McCrudden, F. H., ii, 1136.

McDermott, F. A., ii, 1113.

MacInnes, D. A. See E. W. Washburn.

McMaster, L. See E. H. Keiser.

McWilliam, A., and E. J. Barnes, ii, 1092.

Majima, R., and Y. Aoki, i, 992.

Malinowski, W. See W. Steinkopf.

Mameli, E. See G. Oddo.

Mannessier, A. See G. Oddo.

Manning, M. F. See O. Klotz.

Mantovani, E. See G. Oddo.

Marchlewski, L., ii, 1125.

Marcus, E. See W. Biltz.

Markoff, I., F. Müller, and N. Zuntz, ii, 1107.

Marino-Zuco, F., and I. Foa, i, 1049.

Marino-Zuco, F., L. Giuganino, and R. Onorato, ii, 1108.

Marino-Zuco, F., and V. Pasquero, i, 1003.

Maron, D., and D. Salzberg, i, 1032.

Marotta, D., i, 980.

Marshall, J. T. See P. A. Kober.

Martegiani, E. See G. Bargellini.

Mascarelli, L., i, 964.

Masing, E., ii, 1111.

Masloff, A. A. von, ii, 1144.

Matschnevitch, L., i, 981.

May, C. E., ii, 1131.

Mazé, P., ii, 1126.

Mendel, L. B., and M. S. Fine, ii, 1109.

Menschutkin, B. N., i, 992.

Mentzel, W. See A. Michaelis.

Merck, E., i, 1032, 1035.

Meunier, S., ii, 1106.

Meyer, J., i, 975.

Meyer, P. See H. Fischer.

Meyer-Bietz, F. See H. Fischer.

Michaelis, A., F. Abraham, F. Isert, F. Risse, W. Thomas, and F. Walter, i, 1037.

Michaelis, A., F. Doepmann, F. Isert, W. Mentzel, W. Thomas, F. Walter, and E. Wurl, i, 1039.

Michaelis, A., and A. Günther, i, 1056.

Michaelis, L., and H. Davidsohn, i, 1051, 1052.

Michaelis, L. See also H. Lachs.

Micklethwait, (Miss) F. M. G. See G. T. Morgan.

Möbr, E., i, 958.

Moore, B., H. E. Roaf, and A. Webster, ii, 1072.

Morgan, A. F. See H. G. Byers.

Morgan, G. T., and (Miss) F. M. G. Micklathwait, *TRANS.*, 2286.
 Morgan, J. L. R., and F. T. Owen, ii, 1067.
 Morgensatern, O., i, 976.
 Merrill, G. F. See A. W. Crossley.
 Moseicki, I., ii, 1057.
 Mossbach, G. See F. Sacha.
 Mouron, C., and A. Lepape, ii, 1087, 1134.
 Mücke, O., ii, 1100.
 Muller, E. R. E., ii, 1132.
 Muller, F. See I. Markoff.

N.

Nernst, W., and F. A. Lindemann, ii, 1059.
 Nicolet, B. H. See H. L. Wheeler.

* From bottom.

Hydrastinine (2 grams) and 2:4-dinitrotoluene (2 grams) were dissolved in boiling methyl alcohol (30 c.c.), and the solution boiled until the yellow, granular precipitate began to separate. After cooling, the substance was collected and recrystallised from a mixture of benzene and methyl alcohol. The yield approximated closely to that demanded by theory.

On analysis of a specimen dried in a vacuum over sulphuric acid: 0.1201 gave 0.2568 CO_2 and 0.0482 H_2O . $\text{C}=58.3$; $\text{H}=4.4$.

$\text{C}_{15}\text{H}_{17}\text{O}_4\text{N}_3$ requires $\text{C}=58.2$; $\text{H}=4.6$ per cent.

The substance crystallises in microscopic balls of needles, is pale yellow, and melts at $143\text{--}144^\circ$ with vigorous decomposition at a slightly higher temperature. It is very sparingly soluble in hot or cold alcohol, but readily so in benzene.

The *hydrochloride* is sparingly soluble in cold water, and can be crystallised from hot dilute hydrochloric acid. It forms pale yellow prisms.

The *picrate* is best prepared by mixing a hot solution of the base with methyl ethyl ketone with a solution of picric acid in the same solvent. It forms pale yellow prisms, melting at $172\text{--}173^\circ$, and very sparingly soluble in the usual solvents.

The decomposition of this substance on boiling with acetic acid quite similar to that of anhydrocotarnine-2:4-dinitrotoluene. The most colourless solution of the base in glacial acetic acid acquires yellow colour on boiling, and on dilution with water, needles, melting at 68° and consisting of dinitrotoluene, separate from the solution. The filtrate from these exhibits a strong bluish-green fluorescence showing the presence of hydrastinine.

In conclusion, we desire to thank the Research Fund Committee of the Chemical Society for a grant which has partly defrayed the expenses of this investigation.

THE UNIVERSITY,
 MANCHESTER.

CCXLII.—*The Electrochemistry of Solutions in Acetone*
Part I.By ALEXANDER ROSHNESTWENSKY and WILLIAM CUMMRE
McCULLAGH LEWIS.

WHILST a considerable amount of attention has been directed to the electrochemical behaviour of methyl and ethyl alcohols, relatively few measurements are recorded in the case of solutions in acetone. The present paper contains the results of an investigation undertaken to supply to a certain extent this deficiency. The solutions employed were lithium nitrate and silver nitrate, the latter being examined in greater detail. Before giving our own measurements, it is necessary to indicate briefly some of the results obtained by other observers which bear directly on the results obtained by us.*

As regards the electrolysis of saturated silver nitrate solutions in acetone, Kahlenberg (*J. physical Chem.*, 1900, **4**, 349) found that the metal was precipitated in a coherent form, but "the solution conducts so poorly" that it was impossible to verify Faraday's law. In the same paper Kahlenberg gives some results of electromotive force measurements of $\text{Ag}|\text{AgNO}_3$ concentration cells in pyridine and acetonitrile respectively, with regard to which he concludes that the Nernst expressions are inapplicable. Kahlenberg assumes that the liquid/liquid potential difference is negligible, which, in the case of acetone at least, we shall show later is not the case.

The specific conductivity of acetone itself has been measured by Dutoit and Levier (*J. Chim. phys.*, 1905, **3**, 435), the value obtained being $(2.048) \times 10^{-7}$ mho at the ordinary temperature (using unplatinised platinum electrodes). H. C. Jones and C. A. Rouse (*Amer. Chem. J.*, 1906, **36**, 427) obtained the value 1.0×10^{-6} at 60°; our own result being 6×10^{-7} at 18° (using unplatinised electrodes†).

As regards the molecular conductivity of solutes at infinite dilution (λ_∞) in acetone, considerable vagueness exists. Carrara (*loc. cit.*) states that λ_∞ for triethylsulphine iodide is 167 (as determined by direct experiment). Walden (*Zeitsch. physikal. Chem.*, 1906, **54**, 222) found for tetraethylammonium iodide at 25°

* For a general account of the electrochemistry of non-aqueous solutions compare Carrara: "Elektrochemie der nichtwässrigen Lösungen," *Ahrens' Sammlung*, 12; also Neustadt, *Diss.*, Breslau, 1909.

† These are preferable to platinised ones, as they eliminate the possibility of catalytic reactions when the solvent is an organic substance.

$\lambda_{\infty} = 225$. Dutoit and Levier (*loc. cit.*) give the following values for some simple salts at 18° :

	Li.	Na.	K.	NH_4 .
Br.....	155	158	155.5	157.5
I.....	157	155	157.5	157.5
CN^{\ast}	—	169	170.0	171.0
NO_3	132	—	—	—

^{*} Benz, *Diss.*, Lausanne, 1905.

From these results Dutoit and Levier conclude that Kohlrausch's law of the independent migration of the ions is valid for solutions in acetone. The same authors have applied Ostwald's dilution law to some of the above salts, but find that the "constant" falls with increasing dilution.

In connexion with the question of transport numbers, Carrara (*loc. cit.*) draws the conclusion that in general there is a tendency on the part of each ion to reach a limiting value independent of the nature of the solvent. This scarcely seems to be borne out in the case of acetone, however. In the particular instance of silver nitrate, Jones and Rouiller (*loc. cit.*) state that the solubility of the salt in acetone is too slight to make a direct determination of the transport number, but that a value may be obtained by extrapolation from results obtained in acetone-water mixtures, the acetone concentration rising from zero to 75 per cent. Naturally, the extrapolation is a rather large one, and Jones and Rouiller are only felt justified in giving the result as an inequality, namely, the transport number of NO_3 at 25° in acetone > 0.62 .

Experiments with methyl alcohol-acetone mixtures also lead on extrapolation to a value for the transport number greater than 0.6.

EXPERIMENTAL.

Kahlbaum's acetone was twice distilled over metallic calcium, the middle fraction being kept in a glass bottle, from which moisture was carefully excluded by calcium chloride tubes.

The most concentrated solution of silver nitrate conveniently prepared was 0.02*N*. The solvent and solutions were kept, and the measurements carried out in weak artificial light, as it was noticed that on exposure to sunlight a brown precipitate forms in the solutions. Under the conditions specified the solutions remain permanently homogeneous.

I.—Conductivity Measurements.

The usual Wheatstone bridge and telephone method was employed. The cell, from which moisture was excluded, contained

two large unplatinised platinum plates close together, the κ -constant being small, namely, 0.09213.

The measurements were made at 18°, an oil-bath being employed as the resistances were in all cases fairly large. The following table contains the specific and molecular conductivities of silver nitrate

TABLE I.

Concentration in gram-mols./litre.	Specific conductivity (mhos) $\times 10^3$.	λ_r Molecular conductivity
0.02	14.37	7.19
0.01	10.17	10.17
0.007	7.42	10.60
0.005	5.50	11.00
0.0035	3.97	11.34
0.002	2.51	12.54
0.001	1.46	14.62
0.0005	0.95	19.68

Our values at 18° are slightly lower than those of Laszczynski and slightly higher than those of Jones and Rouiller (at 25°).

The value of λ_∞ for silver nitrate cannot be obtained directly. The empirical expression $\lambda_\infty \eta = \text{constant}$ (compare Walden, *Zeitsch. physikal. Chem.*, 1906, 55, 207) independent of the solvent, η being the viscosity of the solvent, does not appear to hold for acetone; thus, on comparing the viscosities of water and acetone, one finds that λ_∞ for silver nitrate in acetone = 371, a value which is certainly too great. Again, Kohlrausch's expression, $\lambda_r = \lambda_\infty - a\sqrt{c}$, where a is a constant and c the concentration, has found application in those cases in which λ_r is a linear function of \sqrt{c} ; although this condition is approximately fulfilled in the present instance, the values for λ_∞ given by the formula vary from 45 to 78.

A moderate approximation may, however, be obtained in the following way: According to Laszczynski, λ_∞ for simple salts in acetone is 1.3 times that in water. For silver nitrate at 18° $\lambda_\infty = 116$, and hence in acetone $\lambda_\infty = 151$. This is not very different from the directly determined values for alkali bromides and iodides in acetone ($\lambda_\infty = 155$ —160, Dutoit and Levier), and since in water the λ_∞ for silver nitrate does not differ much from that of these salts, we have assumed that the same holds for acetone solutions and have taken λ_∞ for silver nitrate = 150. The conclusions which we draw from the results in which λ_∞ is employed are not invalidated, even if a large percentage error (up to 30 per cent.) were involved in this quantity; further, the majority of the electromotive force measurements given later are independent of λ_∞ .

The following table contains the degrees of dissociation of silver nitrate in acetone, the Ostwald dilution law $\alpha^2/(1-\alpha)v$, and the

empirical expressions $\alpha^2/(1-\alpha)^2v$ and $\alpha^2/(1-\alpha)\sqrt{v}$ of van't Hoff and Rudolphi respectively.

TABLE II.

Molar concentration.	$\alpha = \lambda_v/\lambda_\infty$.	Ostwald K.	van't Hoff K.	Rudolphi K.
0.02	0.048	0.04 ₄ 18	0.0 ₂ 244	0.0 ₁ 342
0.01	0.068	50	362	496
0.007	0.070	37	277	442
0.005	0.073	29	256	407
0.0035	0.075	21	173	360
0.002	0.084	15	141	345
0.001	0.097	14	102	329
0.0005	0.131	09	149	441

The Ostwald constant falls steadily as the dilution increases. The van't Hoff constant is also not very satisfactory, the most consistent values being given by Rudolphi's formula. It is thus apparent that silver nitrate in acetone behaves like a strong electrolyte in not obeying Ostwald's law, but at the same time the extent of the dissociation is that of a weak electrolyte (in water). This opens the question as to what is the criterion to be employed to decide whether an electrolyte is "weak" or "strong."

The conductivity of lithium nitrate in acetone (which is required in connexion with the *E.M.F.* measurements) was also determined, with the following result.

TABLE III.

Lithium Nitrate in Acetone at 18°.

Molar concentration.	Specific conc. $\times 10^3$.	λ_v .	$\alpha = \lambda_v/\lambda_\infty$.	Ostwald K.	Rudolphi K.
0.343*	2.4	7.0	0.053	0.02 ₁ 101	0.0 ₁ 176
0.1715	1.39	8.1	0.061	0.067	160
0.0858	0.82	9.54	0.072	0.48	—

0.00032	0.024	75.0	0.568	0.23	0.0120

* Saturated.

The value of λ_∞ for lithium nitrate as determined by Benz (Dutoit and Levier, *loc. cit.*) is 132, and this has been employed in the calculation of the three last columns in the above table.* It will be observed that for dilutions $v > 100$ the Ostwald expression is constant, whilst the Rudolphi formula does not hold—and this

Kohlrausch's formula is also inapplicable here, because λ is not a linear function

in spite of the fact that the dissociation is much greater than in the case of silver nitrate. Dissociation of itself is therefore not necessarily the source of the inapplicability of the Ostwald law. From the data given above it is found that the concentration of NO_3^- in the saturated solution of lithium nitrate is 0.0182 gram NO_3^- per litre at 18° . This quantity is required later.

II.—Electromotive Force Measurements.

A calibrated slide-wire potentiometer (Land- und Seekabelwerke, accurate to 0.1 millivolt) was employed. The Weston cell was taken as standard ($E.M.F. = 1.0183$ volts). Since it was anticipated that the quantity of current which could be obtained from the silver nitrate concentration cells would be very small, a galvanometer was not employed. Instead, an evacuated capillary electrometer was used. This type of instrument suffers as a rule from the defect that its capacity is too great. The vacuum type, however, is much more sensitive than the ordinary form, probably due to the fact that since air is excluded the quantity of Hg^{++} ions in solution is less than in the ordinary instrument, and hence the capacity of the Helmholtz double-layers is less.* Employing the Weston cell as a source of $E.M.F.$, it was observed that with the electrometer readings could be made to 0.1 millivolt. With the silver nitrate-acetone cells the reading is only accurate to 2 millivolts. The sensitivity is therefore not sufficient for very accurate work.

Electromotive Forces which include Liquid/Liquid Potential Difference.

For the ordinary type of cell,

the expression for the electromotive force at 18° is:

$$E = \frac{2v}{u+v} \frac{RT}{nF} \log \frac{a_1 c_1}{a_2 c_2} \text{ or } \frac{2v}{u+v} 0.0577 \log \frac{\lambda_1 c_1}{\lambda_2 c_2},$$

where λ_1, λ_2 are the molecular conductivities at the AgNO_3 concentrations c_1 and c_2 ; $v/u+v$ = transport number of $\text{NO}_3^- = 0.62$.

It was our object to investigate if the Nernst formula held good for acetone solutions. Table IV contains the results obtained, the headings of the columns being self-explanatory.

It will be observed that the differences between observed and calculated values are about as frequently positive as negative. The results obtained therefore support the view that Nernst's formula is applicable. Incidentally, also, the agreement obtained goes to show

* Experiments are being undertaken in this laboratory with a view further to improve, if possible, the sensitivity of the capillary electrometer.

TABLE IV.

* Neustadt measured this combination, his value being 0.016—0.017v, which is in good agreement with our result. Neustadt did not attempt to calculate the E.M.F.

that the value 0.62 for the transport number of NO_3' in acetone must be fairly correct. Employing this, we can calculate the magnitude of the liquid/liquid potential differences (included in the above measurements) by means of the expression:

$$E_1 = \frac{u-v}{u+v} 0.0577 \log \frac{\lambda_1 c_1}{\lambda_2 c_2}.$$

TABLE V.

Liquid/Liquid Potential Difference in Volts (at 18°).

Molar concentration of AgNO_3 .	P.D. calculated.
0.02 : 0.01	0.002
0.02 : 0.001	0.013
0.01 : 0.007	0.001
0.01 : 0.005	0.004
0.01 : 0.002	0.008
0.01 : 0.001	0.012
0.01 : 0.0005	0.014

The liquid/liquid potential difference is therefore not negligible when the concentration-ratio of the salt exceeds 5,

Attempts to Eliminate the Liquid/Liquid Potential Difference

As ammonium nitrate has been frequently employed in aqueous solution to eliminate the liquid potential difference, we had hoped to employ it in the present case, but its solubility in acetone is very slight, as is also the solubility of sodium nitrate. Ammonium acetate dissolves to a certain extent, but it is unsuitable for the purpose, since the solution (in presence of air) darkens, and on pouring it into water a green fluorescence is observed, indicating the formation of a compound. The solubility of potassium nitrate in acetone at 18° was found to be 0.001 gram-molecule per litre. A saturated solution of dry lithium nitrate was under the same conditions found to be 0.343*N*. Owing to its greater solubility, lithium nitrate was therefore employed, although the great inequality in the mobility of its ions in water is not a recommendation.* Two sets of experiments were carried out, (a) with lithium nitrate (or potassium nitrate) interposed between the silver nitrate solutions, and (b) with lithium nitrate present throughout the cell.

(a) Potassium and Lithium Nitrates Interposed.

The following table contains the *E.M.F.* values obtained with potassium nitrate as the middle liquid:

TABLE VI.

Temperature.	Molar concentration of AgNO_3		<i>E.M.F.</i> observed.	<i>E.M.F.</i> observed with KNO_3 interposed.
	c_1 .	c_2 .		
19°	0.01 :	0.007	0.011	0.011
19	0.01 :	0.005	0.024	0.024
20	0.01 :	0.0035	0.028	0.028
19	0.01 :	0.002	0.048	0.037
19	0.02 :	0.007	0.020	0.020
19	0.02 :	0.005	0.031	0.035
20	0.02 :	0.0035	0.045	0.045
19	0.02 :	0.002	0.053	0.052
19	0.02 :	0.001	0.058	0.058

The interposition of potassium nitrate has no reasonable effect, as was to be expected from its slight solubility. The measurements in this case were the most difficult to obtain.

The following table contains the results obtained on interposing saturated lithium nitrate solution (0.343*N*) as the middle liquid:

* This is probably of little significance, however, since the Li ion has been shown to be greatly hydrated in aqueous solution, whilst it may be "normal" in acetone.

TABLE VII.

Temperature.	Molar concentration of AgNO_3		<i>E.M.F.</i> observed.	Increase in <i>E.M.F.</i> in volts due to inter- position of LiNO_3 .
	c_1	c_2		
19°	0.02	0.01	0.019, 0.020	0.005
19	0.02	0.007	0.028	8
19	0.02	0.005	0.041	7
19	0.02	0.0035	0.052	7
19	0.02	0.002	0.068	16
19	0.02	0.001	0.065	7
19	0.02	0.0005	0.134 (?)	47 (?)
19	0.01	0.007	0.017, 0.019	6
19	0.01	0.005	0.034	9
19	0.01	0.0035	0.035	8
20	0.01	0.002	0.064	7
19	0.01	0.001	0.053	8
20	0.01	0.0005	0.075	2
20	0.007	0.005	0.022	8
20	0.007	0.0035	0.023	7
20	0.007	0.002	0.038, 0.039	6
20	0.007	0.001	0.048	6
20	0.007	0.0005	0.063	7

The important fact brought out by the above results is that saturated solution of lithium nitrate *raises* the *E.M.F.* of the cell instead of lowering it, as one would expect in accordance with the following:

$c_1 < c_2$. Liquid/liquid P.D. = E_1 .
Transport number of anion > 0.5 .
Net *E.M.F.* of cell = E .

$E_1 = 0$.
Net *E* should be less
than in previous case.

The lithium nitrate solution, instead of eliminating E_1 , sets up a potential difference of its own in the same sense as the E_1 in the original case.

(b) *Lithium Nitrate Solution Throughout the Cell.*

In view of the abnormal behaviour of lithium nitrate when interposed, it is of interest to examine its effect when distributed throughout the cell, in which case, on theoretical grounds, any convenient electrolyte sufficiently soluble should eliminate the liquid/liquid potential difference. First, it is necessary to tabulate the

values for the silver ion concentration in the various solutions when allowance is made for the presence of the saturated lithium nitrate solution. As we have already seen, this solution gives rise to a NO_3^- concentration 0.0182 gram-ions per litre, which may be regarded as remaining practically constant in all cases, thereby throwing back the dissociation of the silver nitrate to a different extent in each solution. The problem would be easy if silver nitrate in acetone obeyed the dilution law, but this is not the case. As an approximation, however, the silver ion concentration in presence of the lithium salt has been calculated, first, by employing the various values found for the Ostwald "constant" at the corresponding molar concentrations of the silver salt, the results being given in the following table, column 2; and, secondly, by employing the mean of the values of the Ostwald constant, the results in this case being given in the third column.

TABLE VIII.

Molar concentration of AgNO_3 .	$[\text{Ag}^+]$ calculated from the corresponding "K."	$[\text{Ag}^+]$ calculated from the mean $K = 0.024$.
0.02	0.0527	0.0307
0.01	0.0275	0.0154
0.007	0.0142	0.0107
0.005	0.0079	0.0077
0.002	0.0016	0.0033
0.001	0.0077	0.0015
0.0005	0.0025	0.00077

The values of the silver ion concentration thus obtained are used to calculate the *E.M.F.* of the cell (containing lithium nitrate throughout), the formula when there is no liquid/liquid potential difference being:

$$E = 0.0577 \log \frac{[\text{Ag}^+]_1}{[\text{Ag}^+]_2},$$

in which the square brackets denote concentration terms. In the following table are given the observed *E.M.F.*'s, the *E.M.F.* calculated from the data in column 2, table VIII, and the *E.M.F.* calculated from column 3, table VIII, respectively.

TABLE IX.
Temperature 19°.

Molar concentrations of AgNO_3 .	<i>E.M.F.</i> in volts observed.	<i>E.M.F.</i> calculated from col. 2, table VIII.	<i>E.M.F.</i> calculated from col. 3, table VIII.
0.02 : 0.01	0.013	0.0163	0.0173
0.01 : 0.007	0.0122	0.0166	0.009
0.01 : 0.005	0.0245, 0.0249	0.0313	0.0173
0.01 : 0.002	0.060	0.0715	0.085
0.01 : 0.001	0.069	0.0895	0.0583
0.01 : 0.0005	0.086	0.118	0.0750

It may be noted that with lithium nitrate throughout the cell measurements could be made much more easily than in the previous cases. The error does not exceed 0.5 millivolt.

We may also obtain a series of values by calculation, without taking the silver ion concentration values into account, if we assume that the dissociation of silver nitrate approximately obeys the dilution law, and that the dissociation is small compared to that of lithium nitrate. In such a case we have:

$$\begin{aligned} [\text{Ag}^+]_I &= \text{Molar concentration AgNO}_3 \\ [\text{Ag}^+]_{II} &= \text{Molar concentration AgNO}_3 \end{aligned}$$

The values worked out by this method were practically identical with those given in column 4, table IX.

It will be observed that the found values lie between the two series of calculated values. It is therefore impossible to state with certainty whether there is agreement or not, the indefiniteness arising from the fact that silver nitrate does not obey Ostwald's dilution law accurately.

Summary.

(1) Silver nitrate in acetone is only slightly dissociated. It does not, however, obey Ostwald's dilution law, but gives a good constant in Rudolphi's expression.

(2) Lithium nitrate in acetone is much more dissociated than silver nitrate. For dilutions $v > 100$ Ostwald's law holds well. Rudolphi's expression does not hold.

(3) It has been shown that the electromotive force of the silver nitrate concentration cell in acetone at 19°, arranged so as to contain a liquid/liquid potential difference as well as electrode potential differences, is in quantitative agreement with Nernst's formula, the value of the transport number of NO_3^- being taken as 0.62.

(4) The interposition of a saturated solution of lithium nitrate between the two silver nitrate solutions, instead of eliminating the liquid liquid potential difference, increases the latter by several millivolts. The introduction of lithium nitrate throughout the cell has the desired effect so far as it has been possible to decide in view of the approximate nature of our knowledge of the silver ion concentration.

In conclusion, we wish to thank Dr. N. T. M. Wilsmore for the interest which he has taken in these experiments.

PHYSICAL CHEMISTRY LABORATORY,
UNIVERSITY COLLEGE, LONDON.

CCXII.—*Chemical Examination of Calabar Beans.*

By ARTHUR HENRY SALWAY.

THE so-called Calabar beans, the ripe seed of *Physostigma venenosum*, Balfour, have previously been the subject of several investigations, and their most important constituent—the alkaloid physostigmine or eserine—has long been recognised by most of the national Pharmacopœias on account of its valuable medicinal properties.

The first chemical examination of Calabar beans was conducted by Jobst and Hesse (*Annalen*, 1864, 129, 115), who ascertained that their poisonous action is due to an alkaloid, which they designated physostigmine. This substance was obtained by them only as an amorphous, varnish-like mass, but a year later Vée (*Jahresber.*, 1865, 456) succeeded in isolating the alkaloid in a crystalline state. The last-mentioned investigator found that the alkaloid melted at 69°, and proposed for the crystalline base the name eserine. Jobst and Hesse, in a later investigation (*Annalen*, 1867, 141, 913) assigned to physostigmine the formula $C_{15}H_{21}O_2N_3$, but at the same time expressed doubt regarding its crystalline character, although it is now known that under suitable conditions the alkaloid, as stated by Vée (*loc. cit.*), can be obtained in the crystalline form.

In the year 1876 Harnack and Witkowski (*Arch. experim. Path.*, 1876, 401) indicated the presence of a second alkaloid in Calabar beans, for which they proposed the name calabarine. This substance was very indefinite in character, being chiefly distinguished by its tetanus-like effects on the living organism. Subsequent investigations, notably that of Ehrenberg (*Verh. Ges. Deut. Naturf. Aerzte*, 1893, II, 102), have shown that calabarine was in all probability a product of decomposition, and could not have pre-existed in the Calabar bean. It is evident, however, that besides physostigmine a very small proportion of other alkaloids is contained in the Calabar bean; thus, in the year 1888, a crystalline base, differing from physostigmine, was obtained by Böhringer & Söhne (*Pharm. Post*, 1888, 21, 663), and termed by them eseridine. This base was stated to melt at 132°, to be much less poisonous than physostigmine, and on heating with dilute mineral acids to become converted into the latter alkaloid. Eseridine has been further examined by Eber (*Pharm. Zeit.*, 1892, 37, 483), who assigned to it the formula $C_{15}H_{23}O_3N_3$, and it is thus seen to differ from physostigmine only in the elements of one molecule of water.

Ehrenberg (*loc. cit.*) succeeded in isolating a third alkaloid from the Calabar bean. This substance, which is present in extremely

small proportions, was named eseramine, and the empirical formula $C_{16}H_{25}O_3N_4$ assigned to it. It was described as a substance very sparingly soluble in ether and melting at 238—240°. Still another alkaloid of Calabar bean has more recently been described by Ogui (*Arch. Zeit.*, 1904, 19, 891). This base is stated to be isomeric with physostigmine, and therefore designated isophysostigmine. The only information concerning it appears to be the fact that it is insoluble in ether, and yields a sulphate melting at 200—202°.

Little is known regarding the constitution of physostigmine, and practically nothing of the alkaloids associated with it. It therefore seemed desirable to undertake some experiments for the purpose of throwing further light on the chemical constitution of these bases. To achieve this object a large quantity of Calabar beans was obtained and worked up for the isolation of the alkaloids. At the same time, the opportunity was taken to examine more completely the other constituents of the bean. The experiments undertaken in order to elucidate the constitution of physostigmine are reserved for a future communication.

EXPERIMENTAL.

A representative sample of the Calabar beans employed in this investigation, when assayed by the method of the United States Pharmacopœia, yielded 0.091 per cent. of alkaloid. The method referred to, however, was found to give results which were much too low, since the amount of physostigmine isolated when working on the large scale, as described below, was equivalent to 0.179 per cent. of the material employed. The low result by the above method of assay has been ascertained to be due to the fact that three extractions with ether (as required by the Pharmacopœia) are quite insufficient to remove the alkaloid completely from a solution which has been rendered alkaline with sodium hydrogen carbonate.

With the object of testing for the presence of an enzyme, 500 grams of powdered material were mixed with water and kept at the ordinary temperature for forty-eight hours. The liquid was then separated from the mass by filtration under pressure, and alcohol added to the filtrate. A caseous, white precipitate was thus produced, which was collected and dried in a vacuum desiccator over sulphuric acid, when it amounted to 14.5 grams. This substance, which gave the biuret reaction, slowly hydrolysed amygdalin, thus indicating the presence of an enzyme.

A further portion (50 grams) of the powdered bean was successively extracted in a Soxhlet apparatus with various solvents, when

2150 HALWAY : CHEMICAL EXAMINATION OF CALABAR BEANS.

the following amounts of extract, dried at 100°, were obtained:

Petroleum (b. p. 35–50°)	extracted	0.38	grams = 0.76 per cent.
Ether	"	0.08	" = 0.16 "
Chloroform	"	0.18	" = 0.36 "
Ethyl acetate	"	0.13	" = 0.26 "
Alcohol	"	2.32	" = 4.64 "
Total.....		3.09	" 6.18 "

For the purpose of a complete examination of the constituents of the bean 122.7 kilograms of finely powdered material were extracted by continuous percolation with hot alcohol. After removal of the greater part of the alcohol there remained a reddish-brown extract, amounting to 10½ kilograms. This extract, in convenient portions, was mixed with water, and the mixture distilled in a current of steam. The distillate, which contained a very small quantity of essential oil, was extracted with ether, the ethereal solution being washed, dried, and the ether removed. A pale yellow oil possessing a garlic-like odour and amounting to 1.5 grams was obtained.

After the above operation there remained in the steam distillation flask a large quantity of fatty oil floating on the surface of a reddish-brown aqueous liquid, which contained a brown, resinous powder in suspension. The fatty oil was separated, washed well with water, and set aside for subsequent examination, whilst the brown resin was collected and washed with water, the washings being added to the main portion of the aqueous liquid.

Isolation of Physostigmine, $C_{15}H_{21}O_2N_3$.

A small portion of the aqueous liquid was, in the first place, extracted successively with ether and amyl alcohol, but these solvents removed only small quantities of gummy material. The whole of the aqueous liquid was then rendered alkaline with an excess of sodium carbonate, and repeatedly extracted with ether until no further alkaloidal substance was removed by this treatment. The ethereal extracts were united, concentrated to a convenient volume, and then carefully shaken with successive portions of 5 per cent. sulphuric acid until the extract became just acid in reaction. The neutral solution of the sulphate of the alkaloid was then treated with an excess of a saturated solution of sodium salicylate, when the salicylate of the alkaloid was precipitated as an almost colourless, crystalline powder. This was collected, washed well with water, and dried in a vacuum desiccator over sulphuric acid. A further quantity of the salicylate of the alkaloid was obtained from the filtrate by rendering it alkaline with sodium carbonate, extract-

ing with ether, and subjecting the ethereal solution to the same process as that described above. The total crude salicylate thus obtained amounted to 330 grams, representing 219.7 grams of physostigmine, which is equivalent to 0.179 per cent. of the material employed in the investigation. In order to ascertain whether this crude salicylate was homogeneous or not, a considerable portion of the compound was subjected to systematic fractional crystallisation from alcohol. The fractions were found to be uniform in character, crystallising in stout, colourless prisms, melting at 180—181°, and were therefore homogeneous. (Found, C=64.1; H=6.6; N=10.2. Calc., C=63.9; H=6.5; N=10.2 per cent.)

It is evident that the above compound consisted of physostigmine salicylate. The free base was obtained from the latter by agitation with aqueous sodium carbonate in the presence of ether. The ethereal solution of physostigmine thus obtained was dried, and the solvent removed. The pale brown, viscid residuc was dissolved in benzene, and the solution allowed to evaporate slowly at the ordinary temperature in a vacuum desiccator over sulphuric acid. After some time there was deposited a mass of crystals, which was collected and recrystallised several times from a mixture of benzene and petroleum. The physostigmine separated from this solvent in stout prisms, which melted at 86—87°. (Found, C=65.1; H=7.9. Calc., C=65.5; H=7.6 per cent.)

0.2659, made up to 20 c.c. with chloroform, gave $\alpha_D - 2.01'$ in a 2-dcm. tube, whence $[\alpha]_D - 75.8^\circ$.

The above specimen of physostigmine does not agree in melting point with the physostigmine obtained by Pictet and Polonowsky (*Bull. Soc., chim.*, 1893, [iii], 9, 1008), who state that the alkaloid melts at 105—106°. A commercial sample of physostigmine was therefore procured, and this also melted at 105—106°. It was then found that the alkaloid is dimorphous, since the modification melting at 86—87° could be readily converted into the substance melting at 105—106° by recrystallisation in the presence of a crystal of the latter. The optical rotation of the compound melting at 105—106° was determined, and found to be identical with that of the modification melting at 86—87°, as recorded above:

0.3062, made up to 20 c.c. with chloroform, gave $\alpha_D - 2.019'$ in a 2-dcm. tube, whence $[\alpha]_D - 75.8^\circ$.

Pictet and Polonowsky (*loc. cit.*) ascribe to physostigmine an optical rotation, $[\alpha]_D - 82^\circ$, which is somewhat higher than the results obtained above.

Physostigmine does not yield any definite aurichloride or platinum-chloride, but a well-defined *picrate* was obtained, which crystallises

from dilute alcohol in feathery, yellow needles, melting at 114° ; it is only sparingly soluble in hot water, but readily so in alcohol.

Isolation of Eserramine.

The ethereal liquid which had been shaken with dilute sulphuric acid for the separation of the physostigmine as above described was washed with water, dried, and the solvent removed. A small amount (about 2 grams) of a viscid, brown residue was thus obtained, which gradually became solid. Since the solid was not completely soluble in ether, it was digested with a small quantity of the latter, the sparingly soluble portion collected, and then purified by crystallisation from alcohol, when it separated in small, colourless needles, melting and decomposing at 245° . This substance was very sparingly soluble in ether, chloroform, or benzene, but readily so in hot alcohol. It dissolved in strong mineral acids, and yielded a precipitate with Mayer's reagent. It appears from the above properties that the substance is identical with the eserramine of Ehrenberg (*loc. cit.*), but the amount isolated (0.1 gram) did not admit of further examination.

Isolation of a New Alkaloid, Physovenine, $C_{14}H_{18}O_3N_2$.

The ethereal liquid from which the above-mentioned eserramine had been removed, yielded on evaporation a brown, oily residue, which slowly crystallised. The crystals were separated from a little adhering oil, and then crystallised, first from dilute alcohol, and finally from a mixture of benzene and light petroleum. The substance separated from the latter solvent in small, colourless prisms, melting at 123° . The yield of pure substance amounted to 0.6 gram:

0.1024 gave 0.2395 CO_2 and 0.0669 H_2O . $C = 63.8$; $H = 7.3$.

0.1165 " 0.2726 CO_2 " 0.0736 H_2O . $C = 63.8$; $H = 7.0$.

0.1817 " 17.2 c.c. N_2 (moist) at 25° and 764 mm. $N = 10.6$.

$C_{14}H_{18}O_3N_2$ requires $C = 64.1$; $H = 6.9$; $N = 10.7$ per cent.

The above-described alkaloid is not identical with any of the bases previously isolated from Calabar beans, and since no compound of the formula $C_{14}H_{18}O_3N_2$ appears to have been hitherto described, it is proposed to designate the new alkaloid, *physovenine*.

Physovenine, $C_{14}H_{18}O_3N_2$, is very soluble in alcohol, benzene, or chloroform, moderately so in ether, but insoluble in light petroleum or water. It is only a weak base, dissolving in concentrated mineral acids, but being reprecipitated on the addition of water. When physovenine is treated with barium hydroxide, there is an immediate precipitation of barium carbonate, and the solution rapidly

assumes a deep red colour. This behaviour of physovenine is very similar to that of physostigmine, since the latter under the influence of alkalis (Ehrenberg, *loc. cit.*) loses carbon dioxide and methylamine, and becomes converted successively into eseroline and a red colouring matter, rubreserine. It appears probable from the properties and composition of physovenine that the latter is an intermediate product in the conversion of physostigmine into eseroline, as represented by the following equations:

Physovenine is, like physostigmine, very powerfully myotic; thus a single drop of a 0.1 per cent. solution of the alkaloid in dilute alcohol when introduced into the eye produced after an interval of a few minutes a powerful contraction of the pupil, which attained its maximum effect half an hour after the injection.

A portion of the aqueous liquid from which the alkaloids had been extracted as described above, was rendered slightly acid with acetic acid, and then concentrated to a small bulk. A large amount of a viscid syrup was thus obtained, which readily reduced Fehling's solution. It was digested with hot alcohol, the alcoholic liquid decanted, and ethyl acetate added to the latter. In this manner a considerable quantity of a sugar was obtained, which yielded a dioxazone, melting and decomposing at 205°.

The Fatty Oil.

The fatty oil which had been isolated as previously described amounted to 1650 grams. Since it was found to contain a small quantity of alkaloidal substance of weakly basic character, it was extracted with 40 per cent. sulphuric acid. The acid extracts were rendered alkaline and extracted with ether. In this manner a small amount (1.5 grams) of a brown, viscid liquid was obtained, which partly solidified after keeping some time. On examination, the crystalline substance was found to be identical with the alkaloid physovenine, $\text{C}_{14}\text{H}_{18}\text{O}_3\text{N}_2$, previously isolated from the aqueous liquid.

A convenient portion (200 grams) of the fatty oil was next hydrolysed by heating with an excess of potassium hydroxide in the presence of alcohol, when a considerable quantity of ammoniacal vapours was evolved. After this treatment the greater part of the alcohol was removed, water added, and the alkaline liquid repeatedly

extracted with ether. The pale yellow ethereal extract was washed, dried, and the ether removed, when 10 grams of a crystalline residue were obtained. This was dissolved in hot alcohol, from which it separated in colourless leaflets, melting at $132-133^{\circ}$. The substance gave the colour reactions of the phytosterols, and evidently belonged to that class of compounds. Windaus and Hauth (*Ber.*, 1906, 39, 4378; 1907, 40, 3681) have already shown that the phytosterol of Calabar bean is a mixture of two compounds, namely, stigmasterol, $C_{30}H_{48}O$, and sitosterol, $C_{27}H_{46}O$, which were separated by them after conversion into the bromoacetyl derivatives. In order to ascertain whether the above crude phytosterol, melting at $132-133^{\circ}$, consisted of such a mixture, the substance was acetylated, and the acetyl derivative treated with bromine in the presence of acetic acid. The sparingly soluble bromo-derivative which separated was purified by crystallization from a mixture of chloroform and alcohol, and was obtained in colourless leaflets, melting and decomposing at $205-206^{\circ}$. (Found, Br=40.6. Calc., Br=40.7 per cent.) This substance is evidently identical with the tetrahydroacetylstigmasterol described by Windaus and Hauth (*loc. cit.*). When debrominated by means of zinc dust the above compound yielded acetylstigmasterol (m. p. 140°), and the latter on hydrolysis was converted into stigmasterol, melting at 169° .

The mother liquors from the bromination, treated in the same manner, yielded successively acetylsitosterol (m. p. 128°) and sitosterol, $C_{27}H_{46}O$, melting at $134-135^{\circ}$. (Found, C=83.7; H=11.1. Calc., C=83.9; H=11.9 per cent.) It is thus evident that the above crude phytosterol, melting at $132-133^{\circ}$, consists of a mixture of stigmasterol and sitosterol.

Isolation of Trifolianol, $C_{21}H_{34}O_2(OH)_2$.

The alkaline aqueous liquid from which the above-described crude phytosterol had been extracted by ether was acidified with dilute sulphuric acid, when a dark-coloured, semi-solid precipitate of fatty acids was produced. A portion of the precipitate was observed to be sparingly soluble in ether, and this was therefore separately collected, when it formed a dark-coloured solid amounting to 5 grams. This sparingly soluble substance was first digested with hot alcohol which removed the greater part of the colouring matter, and then treated with boiling chloroform. The latter solvent extracted a small amount of a colourless solid, which was purified by crystallization from dilute pyridine, when it separated in microscopic needles melting and decomposing at 295° . When dissolved in chloroform and acetic anhydride and a drop of concentrated sulphuric acid

ided, it gave a transient pink coloration, changing to blue, and then to green. (Found, C=71.4; H=10.2. Calc., C=71.6; H=10.2 per cent.)

The properties of the above compound, together with the result of its analysis, indicate that the substance is identical with trifoliot, $C_{27}H_{34}O_2(OH)_2$, which was first isolated from red clover flowers (Lower and Salway, Trans., 1910, 97, 249). Its identity was confirmed by the formation of diacetyltrifoliotanol, which crystallised as flat, colourless needles, melting at 165—166°. (Found, C=68.9; H=9.2. Calc., C=68.8; H=9.2 per cent.):

0.2118, made up to 20 c.c. with chloroform, gave α_D , $-0^\circ 31'$ in a 2-dm. tube, whence $[\alpha]_D -24.4^\circ$.

Isolation of a New Dihydric Alcohol, Calabarol, $C_{23}H_{34}O_2(OH)_2$.

The sparingly soluble substance which had been digested with chloroform for the removal of the trifoliotanol, as above described, was crystallised from dilute pyridine, when it separated in minute crystals, melting and decomposing at 290—300°. It was found, however, that this substance still contained a considerable proportion of trifoliotanol. A separation was effected by converting the substance into its benzoyl derivative and subjecting the latter to systematic fractional crystallisation from a mixture of chloroform and alcohol. In this manner two benzoyl compounds were isolated, melting at 165—170° and 195—196° respectively. The former was found on analysis to be *dibenzoyltrifoliotanol*:

0.1109 gave 0.3052 CO_2 and 0.0822 H_2O . C=75.1; H=8.2.

$C_{33}H_{44}O_6$ requires C=75.0; H=7.9 per cent.

The benzoyl derivative melting at 195—196° was analysed with the following results:

0.1173 gave 0.3268 CO_2 and 0.0810 H_2O . C=76.0; H=7.7.

0.1088 „ 0.3036 CO_2 „ 0.0768 H_2O . C=76.1; H=7.8.

$C_{31}H_{44}O_6$ requires C=76.0; H=7.5 per cent.

0.1594, made up to 20 c.c. with chloroform, gave $\alpha_D +0^\circ 52'$ in a 2-dm. tube, whence $[\alpha]_D +14.7^\circ$.

It would appear from the above analysis that the benzoyl compound melting at 195—196° is derived from a dihydric alcohol, $C_{23}H_{34}O_2$. In order to isolate this compound in a state of purity a quantity of the original mixture of trifoliotanol and the new alcohol was heated with equal quantities of chloroform and alcohol, the undissolved substance collected. On repeating the process several times a homogeneous compound was obtained, which melted at 245°. This was recrystallised from dilute pyridine, when it separated in colourless, microscopic needles:—

0.0504 gave 0.1351 CO_2 and 0.0460 H_2O . $\text{C}=73.1$; $\text{H}=10.1$.

$\text{C}_{23}\text{H}_{36}\text{O}_4$ requires $\text{C}=73.4$; $\text{H}=9.6$ per cent.

The above substance is thus seen to possess the formula $\text{C}_{23}\text{H}_{36}\text{O}_4$. As it is a new compound it is proposed to designate it *calabarol*, with reference to the source from which it has been obtained.

Calabarol is very sparingly soluble in the usual organic solvents, but dissolves readily in pyridine. When dissolved in acetone anhydride and chloroform and a drop of concentrated sulphuric acid added, a pink coloration is produced, which rapidly changes to blue and then to green. Calabarol yields a *dibenzoyl* derivative, $\text{C}_{23}\text{H}_{36}\text{O}_4(\text{CO}\cdot\text{C}_6\text{H}_5)_2$, which crystallises from a mixture of chloroform and alcohol in well-formed, colourless needles, melting at $195\text{--}196^\circ$. It is readily soluble in ethyl acetate or chloroform, but very sparingly so in alcohol.

The properties of calabarol indicate that it is closely allied to a number of dihydric alcohols, which have been isolated in the laboratories, and which fall into two groups possessing the general formulæ $\text{C}_n\text{H}_{2n-6}\text{O}_4$ and $\text{C}_n\text{H}_{2n-8}\text{O}_4$ respectively. Calabarol, however, appears to belong to a new series of dihydric alcohols which may be represented by the general formula $\text{C}_n\text{H}_{2n-10}\text{O}_4$.

Examination of the Fatty Acids.

The ethereal solution of fatty acids from which trifoliolanol and calabarol had been removed as described above, was washed with water and the ether removed. The residue was dissolved in hot alcohol, when a substance separated, which, after several crystallisations from alcohol, melted at $74\text{--}76^\circ$:

0.3073 required, for neutralisation, 8.85 c.c. $N/10\text{-KOH}$. Neutralisation value = 161.5.

$\text{C}_{22}\text{H}_{44}\text{O}_2$ requires neutralisation value = 165.0.

It appears from this result that the substance is behenic acid (m. p. $80\text{--}82^\circ$), although the melting point is somewhat low for the latter compound. In order, therefore, to effect a further purification, the substance was esterified, and the ethyl ester thus produced then distilled under diminished pressure. The first portion of the distillate having been discarded, the remainder was hydrolysed, when it yielded a fatty acid, melting at 77.5° . (Found, $\text{C}=77.1$; $\text{H}=13.0$. Calc., $\text{C}=77.7$; $\text{H}=12.9$ per cent.):

0.1775 required for neutralisation 5.2 c.c. $N/10\text{-KOH}$. Neutralisation value = 164.3.

$\text{C}_{22}\text{H}_{44}\text{O}_2$ requires neutralisation value = 165.0.

The substance was thus definitely identified as behenic acid.

The remaining portion of the fatty acids was converted into the lead salt, and the latter treated with ether in the usual manner for the separation of the saturated from the unsaturated acids. The portion of lead salt insoluble in ether was collected, and the fatty acids regenerated and crystallised from alcohol. The first crystalline deposits consisted of behenic acid, melting at 77° . The subsequent deposits melted at about $55-60^{\circ}$, and were evidently mixtures. In order to ascertain the constituents of this product, it was dissolved in alcohol and fractionally precipitated by the successive addition of small portions of a concentrated solution of barium acetate. In this manner four fractions were obtained, from each of which the fatty acid was regenerated, then crystallised once from alcohol, and titrated with $N/10$ -potassium hydroxide. The neutralisation values of the several fractions were 202.5, 205.9, 207.0, and 209.5, whilst their melting points were 55° , 59° , 59° , and 60° respectively. These results indicated the presence of palmitic and stearic acids.

The unsaturated acids obtained from that portion of the lead salt which was soluble in ether amounted to 80 grams. When distilled under diminished pressure a yellow oil which passed over at $240^{\circ}/15$ mm. was obtained. An analysis and a determination of the constants led to the following results:

0.1064 gave 0.3004 CO_2 and 0.1128 H_2O . C = 77.0; H = 11.8.

Neutralisation value = 199.6; Iodine value = 139.

$\text{C}_{18}\text{H}_{34}\text{O}_2$ requires C = 76.6; H = 12.1 per cent. Neutralisation value = 198.9; Iodine value = 90.1.

$\text{C}_{18}\text{H}_{32}\text{O}_2$ requires C = 77.1; H = 11.4 per cent. Neutralisation value = 200.4; Iodine value = 181.4.

It is thus evident that the liquid acids consisted of a mixture of palmitic and linolic acids.

Examination of the Resins.

The resin which had been separated from the aqueous liquid in the manner previously described, consisted for the most part of a brown powder, which was very sparingly soluble in the usual organic solvents. This product was mixed intimately with purified sand, the mixture dried, and then extracted in a Soxhlet apparatus successively with petroleum, ether, chloroform, ethyl alcohol, and alcohol.

Petroleum Extract of the Resin.

This consisted of a brown, fatty oil, amounting to 65 grams. In order to ascertain whether the oil contained any alkaloid, it was dissolved in ether, and the ethereal solution shaken with dilute

sulphuric acid. The acid extracts yielded, however, only a very small quantity of a brown oil, which apparently consisted of physostigmine.

The ethereal solution which had been shaken with dilute sulphuric acid was washed, dried, and the solvent removed. The residue was then hydrolysed, and the products of hydrolysis examined in a manner similar to that previously described in connexion with the fatty oil of Calabar bean. The following constituents were found to be present: stigmasterol, sitosterol, trifolianol, calabanol, behenic, palmitic, stearic, oleic, and linolic acids.

Ether, Chloroform, and Ethyl Acetate Extracts of the Resin.

These extracts were dark brown, gummy solids, amounting to 5, 17.5, and 11 grams respectively. They were separately examined, but nothing of a definite nature was isolated from them.

Alcoholic Extract of the Resin.

This was a dark brown syrup amounting to 41 grams. It was dissolved in alcohol, and the solution heated for some time with dilute sulphuric acid. After removal of the alcohol in a current of steam, there remained a black, resinous mass and a deeply coloured aqueous liquid. The former was collected and examined but yielded nothing definite. Since a small portion of the aqueous liquid gave a precipitate with Mayer's reagent, the whole was rendered alkaline with sodium carbonate, and the alkaline mixture extracted repeatedly with ether. The ethereal extracts were united and agitated with small portions of dilute sulphuric acid until the liquid was just acid in reaction. The extracts thus obtained were treated with a concentrated solution of sodium salicylate, yielding 3 grams of a crystalline solid, which was found to be identical with physostigmine salicylate, melting at 180—181°.

The alkaloid isolated as above described could not have existed as such in the alcohol extract of the resin, but was evidently present in some form of combination.

Summary.

The results of this investigation have shown that the Calabar bean (*Physostigma venenosum*, Balfour) contains, in addition to some essential oil, resin, and other amorphous substances, the following compounds:

Physostigmine, $C_{15}H_{21}O_2N_3$.—This alkaloid was found to be dimorphous, since two interconvertible modifications were obtained melting at 86—87° and 105—106° respectively. The amount of

alkaloid isolated was equivalent to 0.179 per cent. of the Calabar beans employed.

Physoremine, $C_{14}H_{18}O_3N_2$, a new alkaloid, melting at 123° . Like *physostigmine*, it produces a powerful myotic effect on the pupil of the eye.

Eseramine, an alkaloid melting at 245° .

Calabarol, $C_{23}H_{36}O_4$, a new dihydric alcohol (m. p. 245°), which yields a *dibenzoyl* derivative, melting at 195 — 196° .

Trifolianol, $C_{21}H_{36}O_4$, a dihydric alcohol previously isolated from red clover flowers.

Stigmasterol, $C_{30}H_{48}O$, and *sitosterol*, $C_{27}H_{46}O$.

Glycerides of behenic, stearic, palmitic, oleic, and linolic acids.

A sugar yielding *d*-phenylglucosazone (m. p. 205°).

In the course of the present investigation no evidence has been obtained of the presence in Calabar beans of the alkaloid designated by Ogui (*loc. cit.*) as "*isophysostigmine*," or of the "*eseridine*" of Bohringer & Söhne (*loc. cit.*).

THE WELLCOME CHEMICAL RESEARCH LABORATORIES,
LONDON, E.C.

CXLIII.—Contributions to the Chemistry of the Terpenes. Part XII. Synthesis of a *Menthadiene* from *Thymol*, and of a *Diethylocyclohexadiene* from *Phenol*.

By GEORGE GERALD HENDERSON and ROBERT BOYD, B.Sc., Carnegie Research Scholar.

Preparation of a Menthadiene from Thymol.

THYMOMENTHOL (hexahydrothymol), $C_{10}H_{18}OH$, was first prepared synthetically by Brunel (*Compt. rend.*, 1905, 140, 252) according to the method of Sabatier and Senderens, namely, by passing a mixture of thymol vapour and hydrogen through a tube containing finely divided nickel at a temperature of 160 — 170° . When heated with either potassium hydrogen sulphate or phosphoric oxide this thymomenthol yielded a menthene, $C_{10}H_{18}$, but as these dehydrating agents tend to bring about intramolecular rearrangements, the constitution of the hydrocarbon obtained by these methods remained uncertain. As we proposed to make use of this menthene for the preparation of a menthadiene, it appeared advisable to attempt to

dehydrate the thymomenthol by means of oxalic acid in order to obviate the risk of rearrangement. This reagent proved effective under suitable conditions.

A quantity of thymomenthol was prepared according to Brunel's method, and some of the product, which is a colourless liquid with a pleasant odour resembling that of mint, was boiled for a considerable time under a reflux condenser with an 8 per cent. aqueous solution of oxalic acid. The result was not satisfactory, little or no change taking place, and the use of stronger solutions led to no improvement. Finally, in order to effect dehydration, it was found necessary to heat the thymomenthol with anhydrous oxalic acid for several days. When the reaction appeared to be completed, the contents of the flask were distilled in a current of steam, with the result that a colourless, oily liquid passed over, whilst a smaller quantity of a non-volatile substance remained in the flask. The liquid distillate was separated from the condensed water, dried with potassium hydroxide, and fractionally distilled. The fraction which boiled at 166—170° was retained, and the portion of higher boiling point again heated with oxalic acid. Ultimately, after further fractionation, we obtained a quantity of a clear, colourless liquid with a pleasant odour, which had the following constants: boiling point 167—169° under atmospheric pressure, D_{20}^{25} 0.8188, n_D^{25} 1.45363. The physical properties of this menthene agree with those of Brunel's preparation, and it is therefore evident that when thymomenthol is dehydrated by means of oxalic acid the product is the same as that obtained by using either potassium hydrogen sulphate or phosphoric oxide.

According to its method of formation from thymomenthol (I), the hydrocarbon must be either Δ^2 - (II) or Δ^3 -menthene (III). We found that it yields the characteristic crystalline nitroschloride, melting at 133°, and is therefore the Δ^3 -isomeride:

The other substance obtained by heating thymomenthol with anhydrous oxalic acid, which did not volatilise with steam, was proved to be *thymomenthyl oxalate*, $\text{C}_2\text{O}_4(\text{C}_{10}\text{H}_{18})_2$, which is formed as an intermediate product. This ester was separated from the other contents of the distillation flask by means of ether, the ethereal solution washed and dried, and the ether removed. On distillation of the residue a clear, colourless liquid passed over, which solidified on keeping. After crystallisation from alcohol the ester was obtained in large, colourless, lustrous prisms, which melted at 90°. It is very readily soluble in ether, benzene, or chloroform.

fairly readily so in alcohol, light petroleum, or acetic acid, and insoluble in water. It is rapidly hydrolysed when heated with aqueous sodium hydroxide, yielding oxalic acid and β -thymomenthol, a crystalline solid melting at 29° :

0.2183 gave 0.5769 CO_2 and 0.2014 H_2O . $\text{C} = 72.1$; $\text{H} = 10.3$.

$\text{C}_{22}\text{H}_{36}\text{O}_4$ requires $\text{C} = 72.1$; $\text{H} = 10.4$ per cent.

From the Δ^3 -menthene a menthadiene was prepared in the following manner: A solution of the hydrocarbon (1 mol.) in about four times its weight of glacial acetic acid was cooled with ice-water, and a cooled solution of bromine (1 mol.) in the same solvent slowly added. The product was poured into water, and the menthene dibromide, $\text{C}_{10}\text{H}_{16}\text{Br}_2$, which separated as a heavy, oily liquid, extracted with ether. The ethereal solution was washed and dried, the ether removed, and the residual liquid distilled under diminished pressure. The dibromide is a colourless, rather viscous liquid, which boils at $125\text{--}128^{\circ}/30$ mm. It is unstable, quickly becoming dark in colour.

The dibromide was heated for several hours on the water-bath under a reflux condenser with excess of alcoholic potassium hydroxide. When no further separation of potassium bromide was observed, the contents of the flask were distilled in a current of steam, and the oily liquid which passed over was separated from the condensed water by agitation with light petroleum. The solution was dried, the petroleum removed by distillation, and the residual liquid purified by repeated distillation over sodium.

The menthadiene, $\text{C}_{10}\text{H}_{16}$, obtained in this manner is a colourless liquid with a pleasant odour somewhat like that of limonene, and has the following constants: boiling point 173.5° under atmospheric pressure, D_4^{20} 0.8337, n_D^{20} 1.46539. It at once reduces potassium permanganate in the cold, and unites additively with bromine, but it does not form a stable tetrabromide at the ordinary temperature, for when more than two atomic proportions of bromine are added, evolution of hydrogen bromide begins. It does not appear to form a nitrosite under the usual conditions. On exposure to the air it absorbs oxygen fairly rapidly:

1.2555 gave 0.8206 CO_2 and 0.2797 H_2O . $\text{C} = 87.7$; $\text{H} = 12.1$.

1.1876 " 0.6064 CO_2 " 0.2070 H_2O . $\text{C} = 88.1$; $\text{H} = 12.2$.

$\text{C}_{10}\text{H}_{16}$ requires $\text{C} = 88.2$; $\text{H} = 11.8$ per cent.

Since Δ^3 -menthene dibromide has the formula

the menthadiene prepared from it by elimination of two

molecules of hydrogen bromide in the manner described above,

the Δ^2 -4-isomeride, with the formula:
$$\begin{array}{c} \text{CH}_3 \cdot \text{CHMe} \cdot \text{CH} \\ \text{CH} = \text{CPr}^i \cdot \text{CH} \end{array}$$

From menthol, through menthyl chloride, Birkenheim (*Ber.*, 1892, 25, 690) prepared a hydrocarbon, $\text{C}_{10}\text{H}_{18}$, with the following constants: boiling point 170° , D_{20}^{25} 0.8160, n_D^{25} 1.4536. By addition of bromine to this compound and subsequent elimination of hydrogen bromide, he obtained a hydrocarbon, $\text{C}_{10}\text{H}_{16}$, which boiled at 172 – 174° and had D_{20}^{25} 0.8408. There can be little doubt that the mentheno and menthadiene which we prepared synthetically from thymol are identical with the corresponding hydrocarbons which Birkenheim obtained directly from menthol.

Preparation of 1:3-Diethylcyclohexadiene from Phenol.

Considering that it would be of interest to compare the properties of the terpenes with those of isomeric hydrocarbons of the formula $\text{C}_{10}\text{H}_{16}$, we proceeded, in the first instance, to prepare a diethylcyclohexadiene from phenol in the following manner:

A quantity of 3:5-diethylphenol was prepared by condensing phenol with diethyl ether in presence of aluminium chloride, according to Jannasch and Rathjen's method (*Ber.*, 1899, 32, 2392), and a mixture of the vapour of this compound and hydrogen was passed through a tube containing finely divided nickel and heated to a temperature of 160 – 170° . A colourless liquid collected in the cooled receiver, which, after purification by fractional distillation, proved to be principally composed of 1:3-diethylcyclohexan-5-ol

$\text{CH}_3 \cdot \begin{array}{c} \text{CHEt} \cdot \text{CH}_2 \\ \text{CHEt} \cdot \text{CH}_2 \end{array} > \text{CH} \cdot \text{OH}$. This compound is a mobile, colourless liquid, with an odour somewhat like that of peppermint. It boils at 203 – 205° under atmospheric pressure, and has D_{20}^{25} 0.8945 and n_D^{25} 1.46450:

0.1728 gave 0.4851 CO_2 and 0.1915 H_2O . $\text{C}=76.6$; $\text{H}=12.3$.

$\text{C}_{10}\text{H}_{20}\text{O}$ requires $\text{C}=76.9$; $\text{H}=12.8$ per cent.

The bulk of the diethylcyclohexanol was boiled for several days under a reflux condenser with anhydrous oxalic acid, and when the dehydration of the alcohol appeared to be complete, the contents of the flask were distilled in a current of steam. A colourless, oily liquid passed over, and was separated from the condensed water by means of ether, while a small quantity of a non-volatile substance was left in the flask. The ethereal solution was dried, the ether removed by distillation, and the remaining liquid fractionally distilled. The principal fraction was redistilled several times over sodium, and finally a liquid of almost constant boiling point was obtained, which gave the following results on analysis:

0.2534 gave 0.8130 CO_2 and 0.2794 H_2O . $\text{C}=87.5$; $\text{H}=12.3$.

0.2848 „ 0.9131 CO_2 „ 0.3140 H_2O . $\text{C}=87.4$; $\text{H}=12.3$.

$\text{C}_{10}\text{H}_{16}$ requires $\text{C}=87$; $\text{H}=13$ per cent.

It appears from these numbers that the liquid consisted for the most part of 1:3-diethylcyclohexene, $\text{C}_{10}\text{H}_{16}$, but contained also a little diethylcyclohexadiene, $\text{C}_{10}\text{H}_{16}$, from which, owing to the proximity of their boiling points, it could hardly be separated by fractional distillation. The latter was probably derived from a little diethylcyclohexenol present in the specimen of diethylcyclohexanol which was used for the preparation. However, it is worth noting in this connexion that, by the action of phosphoric oxide on menthone, Birkenheim (*loc. cit.*) obtained a similar mixture of hydrocarbons which gave on analysis: $\text{C}=87.7$, 87.8 ; $\text{H}=12.3$, 12.4 , and drew the conclusion that both the compounds $\text{C}_{10}\text{H}_{16}$ and $\text{C}_{10}\text{H}_{16}$ are formed from menthone under the conditions mentioned.

The specimen of diethylcyclohexene, prepared as described above and apparently not quite pure, was a colourless liquid with a peculiar odour faintly resembling that of the menthene obtained from thymol. It boils at $163\text{--}166^\circ$ under atmospheric pressure, and has D_4^{20} 0.83141 and n_D^{20} 1.46519. Taking into account its mode of formation, it is obviously the Δ^4 -isomide,

The non-volatile residue from the steam distillation of the dehydration product probably consisted of diethylcyclohexyl oxalate. It was extracted by means of ether, and, after removal of the ether, the oily liquid which remained was subjected to distillation, with the result that it underwent decomposition and yielded more of the hydrocarbon.

The next step was to prepare diethylcyclohexene dibromide, $\text{C}_{10}\text{H}_{16}\text{Br}_2$, and to eliminate two molecules of hydrogen bromide from one molecule of this compound. A cooled solution of bromine (1 mol.) in glacial acetic acid was slowly added to an ice-cold solution of diethylcyclohexene (1 mol.) in the same solvent. After a short time the solution was poured into water, and the dibromide which separated was collected and washed with water. It is a heavy, colourless, oily liquid, which begins to decompose on keeping. The dibromide was heated on the water-bath under a reflux condenser with excess of alcoholic potassium hydroxide, and when the reaction appeared to be completed steam was passed through the mixture. The oily liquid which passed over was extracted from the condensed water by means of light petroleum, the extract dried, the light petroleum removed by distillation, and the residual liquid fractionally distilled. The principal fraction was purified by

repeated distillation over sodium, and finally a liquid of constant boiling point was obtained, which analysis proved to be the desired hydrocarbon:

0.1143 gave 0.3699 CO_2 and 0.1196 H_2O . $\text{C}=88.3$; $\text{H}=11.6$.

$\text{C}_{10}\text{H}_{16}$ requires $\text{C}=88.2$; $\text{H}=11.8$ per cent.

The 1,3-diethylcyclohexadiene, $\text{C}_{10}\text{H}_{16}$, thus obtained is a colourless liquid with a pleasant odour, and has the following constants: boiling point $166\text{--}168^\circ$ under atmospheric pressure, D_4^{20} 0.8659, n_D^{20} 1.47575. The figure for the specific gravity is perhaps incorrect, as the quantity of material was too small for an accurate determination. The hydrocarbon is unsaturated, reducing at once an alkaline solution of potassium permanganate, and uniting additively with bromine. It also appears to resinify on exposure to the air. Since it is formed by elimination of hydrogen bromide from the dibromide of 1:3-diethyl-4-cyclohexene (I), it most probably is 1:3-diethyl-4-cyclohexadiene (II):

It is our intention to examine more fully the character of this hydrocarbon and of some of its isomerides.

We take this opportunity of expressing our thanks to the Carnegie Trustees for a grant which defrayed most of the expense of this work.

CHEMISTRY DEPARTMENT,
THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

CCXLIV.—*The Velocity of Addition of Alkyl Bromides to Cyclic Tertiary Bases.*

By FRANK STEVENSON LONG.

DURING the last twenty years many investigations have been carried out on the reactivity of various alkyl halides. Summaries of these will be found in Burke and Donnan's paper (Trans., 1904, 85, 553), showing that the reactivity of the halide exhibits in general no simple relation to its chemical constitution. Much of the more recent research was foreshadowed by the work of Lengfeld (*Amer. Chem. J.*, 1889, 11, 40), in which the orders of stability towards alkalis on the one hand, and towards silver nitrate and nitric acid

on the other, were contrasted. The relative stabilities in ascending order of magnitude were given as:

(1) Towards alkalis: ethyl, propyl, butyl, *iso*amyl, *isobutyl*, and *isopropyl*.

(2) Towards silver nitrate and acids: *isopropyl*, ethyl, propyl, butyl, *iso*amyl, and *isobutyl*.

These relationships have, in the main, been confirmed by more recent work. As the second order seemed to be the more general, Lengfeld inclined to the belief that the protective influence of the CHMe_2 group apparent in the reactions of *iso*amyl, *isobutyl*, and *isopropyl* compounds towards alkalis was merely a coincidence.

In view of the discovery by Burke and Donnau (*Zeitsch. physikal. Chem.*, 1909, **69**, 148) that the reaction between silver nitrate and alkyl halides is not a simple bimolecular one, it seemed possible that the former series of stabilities (that is, towards alkalis) might be the more normal one, and that the eccentricity of the *isopropyl* compound might be due to some action other than simple replacement of the halogen.

Seeing that the number of velocity constants of addition of cyclic tertiary bases to alkyl halides determined by Menschutkin (*J. Russ. Phys. Chem. Soc.*, 1902, **34**, 411) was small compared with the number determined, using open-chain secondary and tertiary bases, it was thought most useful to utilise this method of investigating the problem. As it was found that quinoline and pyridine combine at an easily measurable rate below 100° with alkyl bromides in *iso*amyl-alcoholic solution, it was decided to adhere to these conditions throughout.

A few preliminary investigations showed that the reaction was strictly bimolecular, and that the velocity constant was unaltered by the addition of excess of either of the reacting substances.

The velocity constants for these three bromides at 92.5 – 92.7° are given in the following table:

	<i>iso</i> Amyl bromide.	<i>isobutyl</i> bromide	<i>isopropyl</i> bromide.
Pyridine	0.175	0.0246	0.0708
β -Picoline	0.133	0.0178	0.0571
α -Picoline	0.071	0.0127	0.0339
Quinoline	0.022	0.0048	0.0138

Thus, *iso*amyl bromide reacts, on the average, seven times and *isopropyl* bromide three times more rapidly than *isobutyl* bromide.

Before considering this result it will be best to take into account the relative reactivities determined by other workers. In the following table these are expressed approximately, taking the smallest velocity constant in each case as unity.

Observer :	n-Propyl.	iso-Propyl.	iso-Butyl.	iso-Amyl.	Reaction with
Williconus (<i>Annalen</i> , 1882, 212, 239)	—	2	1	—	Sodioacetoacetic ester

Present communication ...	14	3	1	7	—

* These represent relative percentage yields. In some cases the iodides were used.

All the anomalies in the above table will be seen to be due to the isopropyl compound. This is perhaps not so very remarkable, seeing that it differs from the others by being a secondary compound; its reactivity towards pyridine is indeed slightly less than that of the bromide of methylhexylcarbinol, the only other secondary bromide examined.

For the other alkyl compounds we have the reactivity increasing normally as the halogen atom is removed from the influence of the two methyl groups.

The bases examined exhibit steric influences in a remarkably regular manner. With every halogen compound employed the reactivities of the various bases are in the same relative order, the relationships being in many cases almost quantitative. This order, commencing with the most reactive, is: Pyridine, β -picoline, α -picoline, lutidine, quinoline, and 2-methylquinoline.

EXPERIMENTAL.

The isoamyl alcohol used as solvent was Kahlbaum's "Pyridine-free" quality. The final adjustment of volume was made after the graduated flasks had been immersed in the thermostat for some time. Times were therefore reckoned from that of the first titration. At definite intervals of time one-tenth of the volume was withdrawn by a warmed pipette, and the reaction arrested by adding cold distilled water. Volhard's thiocyanate method was found to be the most convenient.

The values of the velocity constant were determined from the formula for a bimolecular reaction, namely:

$$\frac{1}{(\theta_2 - \theta_1)} \left(\frac{1}{T_\infty - T_{\theta_2}} - \frac{1}{T_\infty - T_{\theta_1}} \right) \times F = k,$$

where θ_1 , θ_2 are the times in hours, and T_∞ is the calculated titration value when the action was complete.

The titration numbers are converted into normality figures by multiplying by the appropriate factor F .

The Effect of Excess of each Reacting Substance.

99° in thermostat. *iso*Amyl bromide (b. p. 117·5—118·5°) and pyridine (b. p. 114·1—114·5°).

I. 3·02 Grams of *iso*amyl bromide. 1·58 Grams of pyridine. Made up to 100 c.c. with *iso*amyl alcohol.

θ	0	0·33	1·25	3·25	6·50	8·00
20 - T	—	19·91	19·25	17·90	16·05	15·70
k	—	—	0·176	0·181	0·189	0·170

Mean $k = 0·179$

II. 6·04 Grams of *iso*amyl bromide. 1·58 Grams of pyridine in 100 c.c.

θ	0	0·25	3·25	6·50	8·00
20 - T	—	19·89	16·50	13·90	12·20
k	—	—	0·170	0·140	0·170

Mean $k = 0·170$ (omitting 2nd).

III. 3·02 Grams of *iso*amyl bromide. 3·16 Grams of pyridine in 100 c.c.

θ	0	3·25	6·50	8·0
20 - T	19·89	16·00	13·60	11·85
k	—	0·180	0·182	0·180

Mean $k = 0·174$.

These results were sufficient to show that the presence of excess of either of the constituents has no abnormal influence on the velocity of the reaction. The constants for II and III were obtained from the formula:

$$\frac{1}{\theta_2 - \theta_1} \left(\log \frac{a - x_2}{b - x_2} - \log \frac{a - x_1}{b - x_1} \right) = (a - b)k.$$

Determination of the Order of the Reaction.

IV. 3.02 Grams of *iso*amyl bromide. 1.58 Grams of pyridine in 100 c.c. Temperature 94—95° in water-bath.

θ	0	1.5	2.5	2.83	15.6
$20 - T$	20.0	18.8	18.08	17.95	11.6
k	—	0.185	0.214	0.207	0.205

Mean $k = 0.204$.

V. 3.02 Grams of *iso*amyl bromide. 1.58 Grams of pyridine in 50 c.c. 5 C.c. each titration.

θ	0	1.5	2.5	3.5	5	18.5	22
$20 - T$	20.0	17.94	16.85	15.91	14.70	7.96	7.15
k	—	0.191	0.187	0.184	0.180	0.205	0.204

Mean $k = 0.192$.

(a) *Calculation of the Order by van't Hoff's Method.*—Using the change during the first 1.5 hours in each case for dC/dt we have.

$$\log \frac{dC_1}{dt} - \log \frac{dC_2}{dt}$$

$$\text{Order of reaction, } n = \frac{\log \frac{C_1}{C_2}}{\log \frac{C_1}{C_2}} = 1.8 \text{ nearly.}$$

This method is seriously affected by the errors of experiment

(b) *Using the Formula of Noyes* (*Zeitsch. physikal. Chem.*, 1897, 19, 599):

$$n = 1 + \frac{\log \theta_1 - \log \theta_2}{\log C_{20} - \log C_{10}}$$

where θ_1 and θ_2 are the times for the same fractional part of the reaction to be completed when the initial concentrations are C_{10} and C_{20} respectively. A mean value of $n = 1.90$ was obtained graphically.

The reaction may therefore be regarded as strictly bimolecular.

The velocity determinations given below were carried out, except where otherwise stated, at 92.6° in a thermostat; the concentrations were varied from $N/5$ to $4N/5$ in order to keep the velocity between measurable limits. As above, θ represents the time interval in hours, T the titration value in c.c. of $N/10$ -silver nitrate, and k the velocity constant. In experiments VII and VIII the value of the velocity constant at 92.6° was obtained by multiplying the value at 91.5° by the known ratio of the values for pyridine and *iso*amyl bromide at these temperatures.

VI. *iso*Amyl Bromide and Pyridine ($2N/5$).

θ	0	1	2	3	4.06	5	7.25
$1/20 - T$	0.05311	0.05650	0.06053	0.06378	0.06812	0.07168	0.08136
k	—	0.170	0.185	0.182	0.186	0.186	0.179

Mean value of $k = 0.180$.

VII. *isoAmyl Bromide and α -Picoline (N/5) at 91.5°.*

	0	2.00	3	6.25	7.33	7.75	23.41
$100 - T$	19.70	19.20	18.85	18.19	18.03	17.80	15.07

$1/10 - T$	0.10063	0.10421	0.10494	0.10819	0.11080	0.1128	0.1148
k	—	0.0596	0.0540	0.0567	0.0585	0.0577	0.0577

Mean value of $k = 0.0571$.XVII. *iso*Propyl Bromide and Quinoline (4N/5).

θ	0	1	2	3	4	22	25
$1/10 - T$	0.05016	0.05071	0.05118	0.05171	0.05227	0.06313	0.06411
k	—	0.0137	0.0128	0.0129	0.0132	0.0147	0.0147

Mean value of $k = 0.0138$.

In these experiments with *iso*propyl bromide (b. p. 59.5–6) there are indications of a tendency for the "velocity constant" increase with time. With the far more reactive propyl bromide (b. p. 70–71°) this tendency was very pronounced, especially when the base was also rather volatile; for example, with the slightly volatile quinoline we have:

XVIII. *n*-Propyl Bromide and Quinoline (2N/5).

θ	0	19.43	20.63	21.9	71.4
$1/10 - T$	0.1011	0.1543	0.1580	0.1631	0.352
k	—	0.0685	0.0690	0.0708	0.103

whilst with pyridine:

XIX. Propyl Bromide and Pyridine (2N/5).

θ	1.02	3	4.03	7.02	7.50	8.5
$1/10 - T$	0.1155	0.1495	0.1712	0.2421	0.2625	0.290
k	0.388	0.412	0.445	0.501	0.562	0.66

The effect would appear to be due to a concentrated film of reacting substances in the unfilled portion of the flask. This film would become larger as the volume of solution remaining became less, so that the reaction would seem to increase in velocity as time passed. If this explanation be correct, it would indicate that no serious error due to this cause resulted in the other experiments where the velocity constant remained practically constant.

2-Methylquinoline (b. p. 244–245°) reacted so slowly that or

the commencement of its reactions could be followed. Figures were thus obtained which are, however, for this reason untrustworthy; thus with *iso*amyl bromide:

XX. *iso*Amyl Bromide and 2-Methylquinoline (4N/5).

t	0.5	14.75	25.5	26
$10 - T$	0.05053	0.05319	0.05562	0.05571
k	—	0.0047	0.0050	0.0051

The mean value for k (0.0049) gives an indication of the relative velocity. The following determinations are given for comparative purposes:

XXI. *sec*-Octyl Bromide and Pyridine (2N/5).

t	0	2.33	4	5	18.4
$10 - T$	0.1018	0.1096	0.1159	0.1191	0.1712
k	—	0.084	0.088	0.0865	0.94

Mean value for $k = 0.088$.

XXII. *iso*Amyl Iodide (N/5) and Pyridine (2N/5).

t	0	0.5	1.5	2.6	7.2
$10 - T$	0.10	0.43	0.87	1.39	2.86
k	—	0.357	0.301	0.310	0.348

$$\text{Where } k = 2.303 \times \frac{5}{t_2 - t_1} \left(\log_{10} \frac{10 - T_2}{5 - T_2} - \log_{10} \frac{10 - T_1}{5 - T_1} \right).$$

Mean value of $k = 0.329$.

XXIII. *iso*Amyl Chloride and Pyridine (4N/5).

t	0	18.7	19	22.5	28
$10 - T$	0.05005	0.05583	0.05627	0.05898	0.05879
k	—	0.0077	0.0081	0.0077	0.0079

Mean value of $k = 0.00785$.

I desire, in conclusion, to express my indebtedness to Professor T. Hewitt for kind interest and valuable advice. My thanks are also due to the Research Fund Committee of the East London College for a grant which defrayed the cost of the materials employed.

EAST LONDON COLLEGE.

CCXLV.—*Aminoalkylglyoxalines.*

By FRANK LEE PYMAN.

IN view of the great physiological activity of 4(or 5)- β -aminoethylglyoxaline (compare Dale and Laidlaw, *J. Physiol.*, 1910, **41**, 31) the preparation of several of its homologues has been carried out, and these have been physiologically tested by Dr. P. P. Laidlaw of the Wellcome Physiological Research Laboratories, to whom the author is indebted for the results given in this paper. In the connexion the recent preparation of other homologues of this base by Ewins (this vol., p. 2052) may be noted.

Barger and Dale (*J. Physiol.*, 1910, **41**, 19), in dealing with the relationship between the chemical constitution of the amines and their physiological action, have shown that the activity varies greatly with the length of the side-chain; in the fatty series the maximum of activity is attained at hexylamine, whilst the most active phenylalkylamine is phenylethylamine, having a fatty side-chain of two carbon atoms. It appeared, therefore, of interest to determine the optimum length of side-chain for physiological effect in the aminoalkylglyoxalines. For comparison with 4(or 5)- β -aminoethylglyoxaline, 4(or 5)-aminomethylglyoxaline and 4(or 5)- γ -aminopropylglyoxaline were required, but since the latter was not readily accessible its methyl homologue, 4(or 5)- γ -aminobutylglyoxaline, was prepared and tested in its place. Compared with 4(or 5)- β -aminoethylglyoxaline, the activity of these bases proved to be negligible.

4(or 5)-Aminomethylglyoxaline (I) has recently been described by Windaus and Opitz (*Ber.*, 1911, **44**, 1721), who prepared it by Curtius' method from glyoxaline-4(or 5)-acetic acid obtained from histidine. It may, however, readily be prepared synthetically by suitably oxidising 2-thiol-4(or 5)-aminomethylglyoxaline (II). It has previously been shown (this vol., p. 669) that the customary method of oxidising thiolglyoxalines to glyoxalines by means of nitric acid leads, in the case of this compound, to 4(or 5)-hydroxymethylglyoxaline (III). If, however, an oxidising agent not producing nitric acid were employed, the formation of 4(or 5)-aminomethylglyoxaline would be possible. Other oxidising agents were therefore tried, and

It was found that ferric chloride in calculated quantity oxidised 2-thiol-4(or 5)-aminomethylglyoxaline to 4(or 5)-aminomethylglyoxaline in a yield amounting to more than 50 per cent. of the theoretical:

Potassium permanganate is unsuitable for the oxidation of 2-thiol-4(or 5)-aminomethylglyoxaline to 4(or 5)-aminomethylglyoxaline, for it readily attacks the former substance, causing complete rupture of the glyoxaline ring; cold dilute aqueous solutions of potassium permanganate are immediately decolorised by 2-thiol-4(or 5)-aminomethylglyoxaline, but not by 4(or 5)-aminomethylglyoxaline or other glyoxalines not containing the 2-thiol group. This difference in behaviour is ascribed to the possibility of the thiol base reacting in the tautomeric thiocarbamide form as an unsaturated compound.

4(or 5)- γ -Aminobutylglyoxaline was readily prepared as follows:

Ethyl 4(or 5)-glyoxalinemethylacetoacetate (IV) (this vol., p. 1392) was converted into the corresponding ketone, 4(or 5)- γ -ketobutylglyoxaline (V), by hydrolysis with hydrochloric acid. This was next transformed into the oxime, 4(or 5)- γ -oximinobutylglyoxaline (VI), which on reduction by means of sodium amalgam and acetic acid gave 4(or 5)- γ -aminobutylglyoxaline (VII):

A quantity of $\alpha\beta$ -bis[4(or 5)-glyoxaline]-propionitrile (VIII) (this vol., p. 677) which is formed as a by-product in the preparation of $\alpha\beta$ -cyanomethylglyoxaline being available, it was thought of interest to reduce it to $\beta\gamma$ -bis[4(or 5)-glyoxaline]-propylamine (IX), which may be regarded as an aminoethylglyoxaline containing a glyoxalinemethyl substituent. This reduction was carried out with drum and alcohol, and the desired base was obtained, together with another compound, which was probably $\alpha\beta$ -bis[4(or 5)-glyoxaline]-propionic acid (X):

The physiological action of β -bis[4(or 5)-glyoxaline]propylamine is very slight compared with that of 4(or 5)- β -aminoethylglyoxaline.

The two isomeric *N*-methyl derivatives of 4(or 5)- β -aminoethylglyoxaline in which the methyl group substitutes the imino-hydrogen atom of the glyoxaline ring were next prepared. These compounds, 1-methyl-4(and 5)-aminoethylglyoxaline (XI and XII

were obtained by reduction of the corresponding methylcyanomethylglyoxalines. Their physiological action is negligible compared with that of 4(or 5)- β -aminoethylglyoxaline.

4(or 5)-Cyanomethylglyoxaline (XIII) (this vol., p. 676) yields, on methylation with methyl sulphate and alkali a mixture of the 1:4- and 1:5-methylcyanomethylglyoxalines, from which the former can readily be obtained in a pure state, and the latter less readily by fractional crystallisation of the picrates.

1-Methyl-4-cyanomethylglyoxaline (XIV) gave on reduction with sodium and alcohol 1-methyl-4- β -aminoethylglyoxaline (XV) together with small quantities of 1:4-dimethylglyoxaline (XVI) and 1-methylglyoxaline-4-acetic acid (XVII).

1-Methyl-5-cyanomethylglyoxaline (XVIII) when similarly treated yielded 1-methyl-5- β -aminoethylglyoxaline (XIX) and 1:5-dimethylglyoxaline (XX). As the constitution of the 1:4- and 1:5-dimethylglyoxalines has already been determined with a high degree of probability (Trans., 1910, 97, 1814), orientation of the methylated cyanomethylglyoxalines and their other reduction products follows:

1-Methylglyoxaline-4-acetic acid may readily be prepared by hydrolysing 1-methyl-4-cyanomethylglyoxaline with alkali. It

ester, ethyl 1-methylglyoxaline-4-acetate, was prepared by the action of alcoholic hydrogen chloride on 1-methyl-4-cyanomethylglyoxaline:

1-Methylglyoxaline-5-acetic acid (XXI) was obtained by hydrolysing 1-methyl-5-cyanomethylglyoxaline with alkali.

EXPERIMENTAL.

Oxidation of 2-Thiol-4(or 5)-aminomethylglyoxaline to 4(or 5)-Aminomethylglyoxaline.

1.29 Grams of 2-thiol-4(or 5)-aminomethylglyoxaline (this vol., p. 672) were dissolved in 50 c.c. of water, added to a solution of 9.8 grams of ferric chloride in 100 c.c. of water, and the mixture digested for half an hour in the water-bath. Thirty c.c. of 10 per cent. aqueous sodium carbonate were then added, followed by a hot solution of 4.6 grams of picric acid in 100 c.c. of boiling water. The liquor was then boiled with a little animal charcoal and filtered, and on cooling 3.2 grams of pure 4(or 5)-aminomethylglyoxaline dipicrate separated in the first crop; this quantity represents 6 per cent. of the theoretical yield.

4(or 5)-Aminomethylglyoxaline dipicrate crystallises from water in hexagonal or diamond-shaped plates, which melt at 210—211° (corr.). It contains 1H₂O, which is lost at 120°, but not at 100°. The water of crystallisation in this salt is not mentioned by Windaus and Opitz (*Ber.*, 1911, **44**, 1723), who give the melting point as 209°.

0.1749 * lost *nil* at 100°, lost 0.0054 at 120°. H₂O = 3.1.

0.2064 † gave 0.2550 CO₂ and 0.0496 H₂O. C = 33.7; H = 2.7.

C₄H₇N₃·2C₆H₃O₇N₃·H₂O requires C = 33.5; H = 2.6;

H₂O = 3.1 per cent.

4(or 5)-Aminomethylglyoxaline dihydrochloride was prepared by treating the picrate with hydrochloric acid, removing the picric acid by means of ether, evaporating the acid liquor to dryness, and crystallising the residue from water. It separates from water in colourless, prismatic needles, which contain $\frac{1}{2}$ H₂O, and after drying at 100° melt at 244—245° (corr.) after sintering from about 235°. Its aqueous solution is strongly acid:

0.1262, air-dried salt, lost 0.0068 at 100°. H₂O = 5.4.

C₄H₇N₃·2HCl· $\frac{1}{2}$ H₂O requires H₂O = 5.0 per cent.

* Air-dried.

† Dried at 100°.

For anhydrous salt: Found, C=28.0; H=5.6. Calc., C=28.5; H=5.3 per cent.

Windaus and Opitz (*loc. cit.*), who crystallised this salt from a mixture of methyl alcohol and ether, do not mention any water of crystallisation; they state that on heating, the salt sinters from 230° onwards.

4(or 5)-Aminomethylglyoxaline hydrogen oxalate crystallises from water in monoclinic, hexagonal plates, which decompose at 214° (corr.). It is anhydrous, and is sparingly soluble in cold water:

0.2478 gave 0.3155 CO₂ and 0.0898 H₂O. C=34.8; H=4.1.

C₄H₇N₃.2C₂H₂O₄ requires C=34.7; H=4.0 per cent.

4(or 5)-γ-Ketobutylglyoxaline [4(or 5)-Glyoxaline-ethyl Methyl

Fifteen grams of ethyl 4(or 5)-glyoxalinemethylacetate hydrogen oxalate (this vol., p. 1392) were converted into the base, and this boiled under a reflux condenser for three hours with 60 c.c. of hydrochloric acid and 90 c.c. of water. The liquid was then evaporated to dryness under diminished pressure, and the residue dissolved in a little water, mixed with sodium carbonate, and extracted with chloroform. The extract after drying and distillation of the solvent left the ketone as a viscid, brown oil, which solidified on keeping, forming large, buff crystals, melting at 76—78°, and amounting to 4.4 grams; this yield is 64 per cent. of the theoretical.

4(or 5)-γ-Ketobutylglyoxaline crystallises from anhydrous ethyl acetate in stout, colourless, prismatic needles, which melt at 80—81° (corr.). It is very readily soluble in water, alcohol, acetone, or chloroform, readily so in ethyl acetate, and very sparingly so in ether or benzene:

0.1278 gave 0.2854 CO₂ and 0.0882 H₂O. C=60.9; H=7.7.

C₇H₁₀ON₂ requires C=60.8; H=7.3 per cent.

The *picrate* crystallises from water or alcohol in fine, yellow needles, which melt at 192—193° (corr.). It is very sparingly soluble in cold water or alcohol, but fairly readily so in hot water.

0.1088 gave 0.1702 CO₂ and 0.0370 H₂O. C=42.6; H=3.8.

C₇H₁₀ON₂.C₆H₃O₇N₃ requires C=42.5; H=3.6 per cent.

4(or 5)-γ-Oximinobutylglyoxaline,

This oxime is readily prepared in good yield by heating on the water-bath an aqueous solution of the ketone with the calculated

amounts of hydroxylamine hydrochloride and sodium carbonate; on concentrating and cooling the solution, the oxime crystallises out, and is purified by recrystallisation from water.

4(or 5)- γ -Oximinobutylglyoxaline crystallises from water in clear, colourless plates, which melt at 152–153° (corr.). It is sparingly soluble in cold water or acetone, fairly readily so in alcohol or hot water, but very sparingly so in chloroform:

0.2134 gave 0.4284 CO₂ and 0.1407 H₂O. C=54.7; H=7.4.

C₇H₁₁ON₃ requires C=54.9; H=7.3 per cent.

The *picrate* crystallises from water in hard, spherical grains, which melt at 166–168° (corr.). This salt is sparingly soluble in cold, but readily so in hot, water.

4(or 5)- γ -Aminobutylglyoxaline,

2.3 Grams of 4(or 5)- γ -oximinobutylglyoxaline were dissolved in 10 c.c. of alcohol and 5 c.c. of glacial acetic acid. Fifty grams of 3 per cent. sodium amalgam were then added, and the mixture well shaken and cooled with water. Enough water was supplied from time to time to dissolve the separated sodium acetate, and two further quantities, each of 5 c.c., of acetic acid and 50 grams of sodium amalgam were subsequently added. When the sodium amalgam had been used up, the liquor was diluted with about 100 c.c. of water, and poured into a hot solution of 7 grams of picric acid in 200 c.c. of water, when on cooling 4(or 5)- γ -aminobutylglyoxaline dipicrate crystallised out. After recrystallisation from water 4.1 grams of the pure salt were obtained, that is, 45 per cent. of the theoretical.

4(or 5)- γ -Aminobutylglyoxaline *dipicrate* crystallises from water in long, golden, somewhat serrated spikes, which melt at 247° (corr.) to a brown liquid, which then decomposes. This salt is anhydrous, and very sparingly soluble in cold, but fairly readily so in hot, water:

0.1163 gave 0.1638 CO₂ and 0.0350 H₂O. C=38.4; H=3.4.

C₇H₁₁N₃.(C₆H₃O₇N₃)₂ requires C=38.2; H=3.2 per cent.

Reduction of $\alpha\beta$ -Bis[4(or 5)-glyoxaline]-propionitrile.

Nine grams of $\alpha\beta$ -bis[4(or 5)-glyoxaline]-propionitrile hydrogen maleate* were converted into the base in the manner previously described, and this was reduced by means of 5 grams of sodium

* This vol., p. 677; the formula of the base should read C₈H₉N₃.

and 75 c.c. of absolute alcohol. The reaction product was neutralised with hydrochloric acid, made strongly alkaline with sodium carbonate, evaporated to dryness under diminished pressure, and the residue completely extracted with absolute alcohol. After the removal of the bulk of the solvent, the extract was poured into a solution of 20 grams of picric acid in 500 c.c. of boiling water, when a viscous oil separated. After the solution had cooled somewhat it was decanted from the oil and filtered, when it deposited about 3 grams of crystals, melting at 195–200°. The very sparingly soluble oil also became crystalline on cooling, and was extracted with 500 c.c. of boiling water, filtered, and allowed to cool to about 50°, when 5.0 grams of orange needles, melting at 150–153°, separated; these were collected, and the mother liquor allowed to become quite cold, when a further 1.6 grams of crystals melting at about 210°, separated.

The more sparingly soluble picrate was readily purified by crystallisation from water, and proved to be $\beta\gamma$ -bis[4(or 5)-glyoxaline-propylamine tripicrate]; 3.4 grams of this salt were obtained in a pure state, decomposing at 158° (corr.), that is, 18 per cent. of the theoretical. The more easily soluble picrate was less readily purified; it melted and decomposed at 218–220° (corr.) when pure, and was probably $\alpha\beta$ -bis[4(or 5)-glyoxaline]-propionic acid dipicrate:

0.1300, air-dried salt, lost 0.0072 at 100°. $H_2O = 5.5$.

$C_6H_{10}O_2N_4 \cdot (C_6H_5O_7N_3)_2 \cdot 2H_2O$ requires $H_2O = 5.1$ per cent

0.1010 * gave 0.1392 CO_2 and 0.0268 H_2O . $C = 37.6$; $H = 3.0$.

0.1232 * „ 0.1706 CO_2 „ 0.0331 H_2O . $C = 37.8$; $H = 3.0$.

$C_6H_{10}O_2N_4 \cdot (C_6H_5O_7N_3)_2$ requires $C = 37.9$; $H = 2.4$ per cent

The tripicrate crystallises from water in beautiful, orange-yellow, flat needles, which soften from 150° and decompose at 158° (corr.). This salt is sparingly soluble in hot, and very sparingly so in cold, water. It is anhydrous:

0.1330 gave 0.1786 CO_2 and 0.0330 H_2O . $C = 36.6$; $H = 2.8$

$C_6H_{13}N_5 \cdot (C_6H_5O_7N_3)_3$ requires $C = 36.9$; $H = 2.5$ per cent.

The trihydrochloride was prepared by treating the picrate with hydrochloric acid and ether, and after evaporation of the excess of acid was obtained as a colourless varnish. This readily became crystalline when warmed with alcohol. The crystals were collected, dissolved in very little water, and hot alcohol added to the solution.

* Dried at 100°.

when the salt separated in beautiful, colourless, refracting prisms. The air-dried salt contains a molecule of water of crystallisation, which is not lost at 100° , but probably escapes at about 140° , for on heating the salt sinters at this temperature, but then remains unchanged until it melts at $235\text{--}237^{\circ}$ (corr.). It is readily soluble in water, giving an acid solution, but is insoluble in absolute alcohol:

0.1382 gave 0.1730 CO_2 and 0.0730 H_2O . $\text{C}=34.1$; $\text{H}=5.9$.

0.1482 „ 0.1981 AgCl . $\text{Cl}=33.1$.

$\text{C}_7\text{H}_{13}\text{N}_3 \cdot 3\text{HCl} \cdot \text{H}_2\text{O}$ requires $\text{C}=33.9$; $\text{H}=5.7$; $\text{Cl}=33.4$ per cent.

Methylation of 4(or 5)-Cyanomethylglyoxaline.

Twenty grams of 4(or 5)-cyanomethylglyoxaline (this vol., p. 676) were dissolved in 80 c.c. of 10 per cent. aqueous sodium hydroxide, and shaken with 16 grams of methyl sulphate added gradually while the liquid was shaken and cooled by running water. Another 70 c.c. of 10 per cent. aqueous sodium hydroxide and 16 grams of methyl sulphate were then added. The clear brown liquor was completely extracted by chloroform, and the solvent removed from the extract, when a brown oil resulted. This was dissolved in water, and poured into 2100 c.c. of warm 2 per cent. picric acid solution, when most of the 1-methyl-4-cyanomethylglyoxaline picrate crystallised out at once in a pure state. On concentrating the mother liquors, 1-methyl-5-cyanomethylglyoxaline picrate separated out, mixed with small quantities of its isomeride, and it was purified by recrystallisation from water.

There were isolated 28.5 grams of 1-methyl-4-cyanomethylglyoxaline picrate, melting at $209\text{--}210^{\circ}$ (corr.), and 9.9 grams of 1-methyl-5-cyanomethylglyoxaline picrate, melting at $156\text{--}157^{\circ}$ (corr.), these quantities amounting to 43 and 15 per cent. of the theoretical respectively.

This base crystallises from chloroform in clusters of plates, which melt at $34\text{--}36^{\circ}$ (corr.). It is very deliquescent, and readily soluble in water and the usual organic solvents, with the exception of ether and light petroleum:

0.1337 * gave 0.2917 CO_2 and 0.0731 H_2O . $\text{C}=59.5$; $\text{H}=6.1$.

$\text{C}_6\text{H}_7\text{N}_3$ requires $\text{C}=59.5$; $\text{H}=5.8$ per cent.

The hydrogen oxalate crystallises from water or alcohol in

* Dried at 100° .

prismatic needles, which melt at 116—117° (corr.). It is readily soluble in water, but sparingly so in alcohol:

0.1503 gave 0.2496 CO₂ and 0.0572 H₂O. C=45.3; H=4.3

0.1143 „ 19.6 c.c. N₂ at 18° and 759 mm. N=20.2.

C₆H₇N₃.C₂H₂O₄ requires C=45.5; H=4.3; N=19.9 per cent.

The *picrate* crystallises from water in flat, fern-like clusters of stout needles, or in rods of a rather pale yellow colour, which melt at 209—210° (corr.). It is anhydrous, and is very sparingly soluble in cold, but fairly readily so in hot, water:

0.1530 gave 0.2290 CO₂ and 0.0395 H₂O. C=40.8; H=3.0

C₆H₇N₃.C₆H₃O₇N₃ requires C=41.1; H=2.9 per cent.

The *mercurichloride* and *mercuri-iodide* both readily crystallise from water in long needles.

This base was obtained as an oil, which did not crystallise when kept for several hours at 0°. It is readily soluble in water, alcohol or chloroform.

The *hydrogen oxalate* crystallises from alcohol in prisms, which sinter slightly from 135°, and melt and effervesce at 139—140° (corr.). It is anhydrous. It is readily soluble in water, but sparingly so in alcohol:

0.1580 gave 0.2632 CO₂ and 0.0612 H₂O. C=45.4; H=4.3.

C₆H₇N₃.C₂H₂O₄ requires C=45.5; H=4.3 per cent.

The *picrate* crystallises from water in large, pale yellow, glistening leaflets, which melt at 156—157° (corr.). This salt is anhydrous, sparingly soluble in cold, but readily so in hot, water:

0.1507 gave 0.2284 CO₂ and 0.0411 H₂O. C=41.3; H=3.1.

C₆H₇N₃.C₆H₃O₇N₃ requires C=41.1; H=2.9 per cent.

0.75 Gram of 1-methyl-4-cyanomethylglyoxaline was dissolved in 20 c.c. of water, and boiled with 10 c.c. of 10 per cent. aqueous sodium hydroxide until no more ammonia was evolved. Then 9 c.c. of 10 per cent. hydrochloric acid were added, followed by 1.5 grams of picric acid in 40 c.c. of boiling water. On cooling 1.5 grams of 1-methylglyoxaline-4-acetic acid *picrate* separated in large, striated prisms, melting at 187—189° (corr.), and a further 0.4 gram equally pure was obtained on concentrating the mother liquor, the yield thus amounting to 83 per cent. of the theoretical.

0.1209 gave 0.1751 CO_2 and 0.0332 H_2O . $\text{C} = 39.5$; $\text{H} = 3.1$.
 $\text{C}_4\text{H}_7\text{O}_2\text{N}_2 \cdot \text{C}_6\text{H}_5\text{O}_7\text{N}_3$ requires $\text{C} = 39.0$; $\text{H} = 3.0$ per cent.

Ethyl 1-Methylglyoxaline-4-acetate, $\text{C}_4\text{H}_5\text{N}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$.

Eight grams of 1-methyl-4-cyanomethylglyoxaline picrate were converted into the base, and this boiled for two hours with 50 c.c. of 15 per cent. absolute alcoholic hydrogen chloride, when ammonium chloride separated. The mixture was evaporated to dryness under diminished pressure, dissolved in water, mixed with sodium carbonate, and extracted with chloroform, when ethyl 1-methylglyoxaline-4-acetate was obtained as a brown oil. This was converted into the picrate, and purified by crystallisation from water, when 4.2 grams of the pure salt were obtained, that is, 42 per cent. of the theoretical.

Ethyl 1-methylglyoxaline-4-acetate picrate crystallises from water in long, yellow fibres, having the appearance of glass wool. It is very sparingly soluble in cold, but readily so in hot, water. It melts at $133-134^\circ$ (corr.):

0.1092 * gave 0.1700 CO_2 and 0.0370 H_2O . $\text{C} = 42.4$; $\text{H} = 3.8$.
 $\text{C}_4\text{H}_{12}\text{O}_2\text{N}_2 \cdot \text{C}_6\text{H}_5\text{O}_7\text{N}_3$ requires $\text{C} = 42.3$; $\text{H} = 3.8$ per cent.

1-Methylglyoxaline-5-acetic Acid, $\text{CO}_2\text{H} \cdot \text{CH}_2 \cdot \underset{\text{CH}=\text{N} \geq \text{CH}}{\overset{\text{C} \cdot \text{NMe}}{\text{C}}}$.

This compound was prepared by hydrolysis of its nitrile, and isolated as the *picrate*. This salt crystallises from water in beautiful, hexagonal plates, which melt at $180-181^\circ$ (corr.), after entering a few degrees earlier. It is anhydrous and sparingly soluble in cold, but readily so in hot, water:

0.1200 gave 0.1733 CO_2 and 0.0358 H_2O . $\text{C} = 39.4$; $\text{H} = 3.3$.
 $\text{C}_4\text{H}_7\text{O}_2\text{N}_2 \cdot \text{C}_6\text{H}_5\text{O}_7\text{N}_3$ requires $\text{C} = 39.0$; $\text{H} = 3.0$ per cent.

Reduction of 1-Methyl-4-cyanomethylglyoxaline.

Seven grams of 1-methyl-4-cyanomethylglyoxaline were reduced by means of 10 grams of sodium and 100 c.c. of absolute alcohol. The reaction product was acidified with hydrochloric acid, made strongly alkaline with sodium carbonate, evaporated to dryness under diminished pressure, and the residue extracted with alcohol. The alcoholic extract was evaporated to dryness, and the residue extracted successively with ether, ethyl acetate, and absolute alcohol.

The ethereal extract amounted to 3.0 grams; it was dissolved

* Dried at 100° .

in water, and poured into a litre of warm 1 per cent. aqueous picric acid, when 6.6 grams of 1-methyl-4-β-aminoethylglyoxaline dipicrate separated in a pure state on cooling. The mother liquor was extracted with ether to remove free picric acid and evaporated to low bulk, when about 0.5 gram of a crude picrate, melting at about 140°, separated. After several crystallisations from water, a very small amount of 1:4-dimethylglyoxaline picrate was isolated from it, but was not obtained quite pure. This salt melted at 162–163° (corr.), the pure salt (Trans., 1910, 97, 1819, melting at 167–168° (corr.) in the same bath, whilst a mixture of the two melted at 162–163° (corr.), and a mixture of this salt with 1:5-dimethylglyoxaline picrate at 135–140°.

The ethyl acetate extract afforded a further 1.3 grams of pure 1-methyl-4-β-aminoethylglyoxaline dipicrate, so that the total yield of this compound amounted to 7.9 grams, that is, 23 per cent. of the theoretical.

The absolute alcohol extract gave, with picric acid, at first an amorphous precipitate, but later a small quantity of 1-methylglyoxaline-4-acetic acid picrate.

1-Methyl-4-β-aminoethylglyoxaline,

The dipicrate crystallises from water in large, flat needles, which melt at 217° (corr.). It is very sparingly soluble in cold water and is anhydrous:

0.1803 gave 0.2468 CO₂ and 0.0498 H₂O. C=37.3; H=3.1.

C₆H₁₁N₃.(C₆H₃O₃N₃)₂ requires C=37.0; H=2.9 per cent.

The dihydrochloride was prepared from the dipicrate by means of hydrochloric acid and ether. It crystallises from absolute alcohol in colourless prisms, which melt at 204–206° (corr.), after drying at 100°. It is deliquescent, and readily soluble in water, but sparingly so in absolute alcohol:

0.1186 * gave 0.1596 CO₂ and 0.0708 H₂O. C=36.7; H=6.7.

C₆H₁₁N₃.2HCl requires C=36.4; H=6.6 per cent.

Reduction of 1-Methyl-5-cyanomethylglyoxaline. Formation of 1-Methyl-5-β-aminoethylglyoxaline.

Three grams of 1-methyl-5-cyanomethylglyoxaline were reduced by means of sodium and alcohol, and the products worked up as in the case of the 1:4-compound.

The combined ethereal and ethyl acetate extracts gave first an amorphous picrate, then small quantities of 1-methyl-5-β-amino

ethylglyoxaline dipicrate, which formed yellow needles, melting at 201° (corr.), after drying at 100° :

0.1181 g. gave 0.1615 CO_2 and 0.0305 H_2O . $\text{C}=37.3$; $\text{H}=2.9$.

$\text{C}_8\text{H}_{11}\text{N}_3(\text{C}_6\text{H}_3\text{O}_7\text{N}_3)_2$ requires $\text{C}=37.0$; $\text{H}=2.9$ per cent.

The mother liquor from this salt then gave a small quantity of 1:5-dimethylglyoxaline picrate in clusters of slender needles, melting at $167\text{--}168^{\circ}$ (corr.):

0.0907 g. gave 0.1345 CO_2 and 0.0267 H_2O . $\text{C}=40.4$; $\text{H}=3.3$.

$\text{C}_7\text{H}_8\text{N}_2\text{C}_4\text{H}_3\text{O}_7\text{N}_3$ requires $\text{C}=40.6$; $\text{H}=3.4$ per cent.

This salt was identified by determination of the melting points of its mixtures with pure 1:4- and 1:5-dimethylglyoxaline picrates (Trans., 1910, 97, 1819), when it was found that the mixture with the 1:4-salt melted at $135\text{--}140^{\circ}$, whilst that with the 1:5-salt still melted at $167\text{--}168^{\circ}$ (corr.).

The alcoholic extract gave a very small quantity of a crystalline picrate which melted at $162\text{--}175^{\circ}$; it was probably impure methylglyoxaline-5-acetic acid picrate, but the quantity obtained was insufficient for identification.

THE WELLCOME CHEMICAL WORKS,
DARTFORD, KENT.

CXLVI.—*The Probable Cause of the Elimination of a Carbethoxyl Group as Ethyl Carbonate by the Action of Sodium Ethoxide.*

By FERDINAND BERNARD THOLE and JOCELYN FIELD THORPE.

SEVERAL instances have now been recorded in which the passage of an open-chain δ -cyanoethyl salt into an imino-derivative of *cyclopentane* through the agency of cold alcoholic sodium ethoxide is accompanied by the elimination of a carbethoxy-group as ethyl carbonate. It is sufficient for our purpose to select two examples of this type of reaction from the recent experiments of Mitchell and Thorpe (Trans., 1910, 97, 2261) on the formation of imino-derivatives of α -hydrindone. It was then shown that ethyl α -cyanobenzylmalonate (I) was transformed into ethyl 1-iminohydrindene-carboxylate (II), and that ethyl α -o-dicyano- β -phenylpropionate (III) was converted into 1-imino-2-cyanohydrindene (IV).

It was suggested that these and other reactions of the same kind

* Dried at 100° .

might be due to spatial conditions, and that, in the five-membered ring, the presence of two groups of large molecular volume attached

to any one carbon atom might not be a condition of stability, and consequently, when the compound was treated by a suitable reagent, one of these groups was eliminated.

An examination of the facts shows that several derivatives of the five-carbon ring are known which have more than one carbethoxyl group attached to any one carbon atom, such as, for example, ethyl *cyclopentane-1:1:3:3-tetracarboxylate* (V) and ethyl *hydrindene-2:2-dicarboxylate* (VI):

If our hypothesis is correct, these compounds should pass, on treatment with sodium ethoxide, into ethyl carbonate and the corresponding ethyl esters, thus:

and

We have therefore prepared these compounds, the former by Pospischill's method (*Ber.*, 1898, 31, 1950) from the disodium derivative of ethyl butanetetracarboxylate by the action of methylene iodide, and the latter by v. Baeyer and Perkin's method (*Ber.*, 1884, 17, 122) from *o*-xylene dibromide and ethyl sodiummalonate.

We find that both these esters are quite unacted on by cold alcoholic sodium ethoxide. It is evident, therefore, that the

influences causing the elimination of the carbethoxyl group prior to the formation of the five-ring imino-compounds cannot be ascribed to spatial conditions or to the over-weighting of any one carbon atom of the ring. A careful review of the facts showed, moreover, that the displacement of the carbethoxy-group by sodium in the manner illustrated by the equation:

could not be the determining cause of this reaction, because, *inter alia*, ethyl 1-iminohydrindene-2-carboxylate (II) and analogously substituted compounds do not react with sodium ethoxide to form sodium derivatives. Finally, we decided to compare the various cases of compounds in which this reaction had been noticed, and ultimately arrived at an explanation, which forms the subject of the present communication.

During some experiments on the constitution of glutaconic acid (trans., 1905, 87, 1681) it was found that ethyl α -cyano- $\alpha\beta\gamma$ -trimethylglutaconate (VII) when treated with sodium ethoxide was converted into ethyl α -cyano- $\alpha\beta\gamma$ -trimethylcrotonate (VIII) and ethylcarbonate, thus:

A comparison of ethyl α -cyano- $\alpha\beta\gamma$ -trimethylglutaconate (VII) with the normal ring-compound from ethyl α -cyanobenzylmalonate shows that these substances have one important point in common, namely, that it is necessary for each of them to part with a carbethoxyl group before the hydrogen atom necessary to permit the substance to react in its tautomeric form can be acquired, thus:

(Tautomeric forms.)

This view at once suggests a close relationship between compounds having the complex $\text{HC} \cdot \text{C} \cdot \text{C}$ and those, such as the imino-compounds, which have the complex $\text{HC} \cdot \text{C} \cdot \text{NH}$, and leads to the

general conclusion that when the terminal hydrogen atoms in systems of this type are all replaced, the tendency for the compound to acquire that hydrogen atom which is necessary to enable it to react in its tautomeric form is such that any group capable of replacement by hydrogen is at once eliminated in the presence of a suitable reagent.

In the next communication several instances are recorded in which this reaction has been employed for the preparation of substituted glutaconic acids. These examples clearly prove that when the mobile hydrogen atoms in derivatives of glutaconic acid are replaced, the tendency for the compound to acquire the mobile atom causes it to eliminate one carboxyl group as ethyl carbonate when it is treated with alcoholic sodium ethoxide.

EXPERIMENTAL.

Ethyl Hydrindene-2:2-dicarboxylate,

This substance was originally prepared by v. Baeyer and Perle (*Ber.*, 1884, 17, 122) by the condensation of *o*-xylylene dibromide and the sodium compound of ethyl malonate. It was, however, hydrolysed to the acid without further purification. The method of preparation used by us was the same as that employed by these chemists, but we find that the ester boils at 186°/19 mm., and that it sets to a crystalline mass on cooling. When recrystallised from a small quantity of alcohol it is obtained in long needles, which melt at 38°:

0.2030 gave 0.5092 CO₂ and 0.1272 H₂O. C=68.81; H=6.9.

C₁₆H₁₆O₄ requires C=68.7; H=6.9 per cent.

The ester is quite unaltered by sodium ethoxide.

Ethyl cyclopentane-1:1:3:3-tetracarboxylate,

This substance was prepared by Pospischill's method (*Ber.*, 1893, 31, 1950) from ethyl butanetetracarboxylate,

which was obtained both by the condensation of ethylene dibromide and ethyl sodiomalonate and by the condensation of ethyl cyclopropane-1:1-dicarboxylate, which is also formed in this action, with a further quantity of the sodium compound of ethyl malonate. The desired ester was obtained by condensing ethyl butanetetracarboxylate with methylene iodide. We find that it can be distilled:

under 15 mm. pressure when small quantities are employed, and boils at 225–227°:

0.2013 gave 0.4201 CO_2 and 0.1342 H_2O . $\text{C}=56.93$; $\text{H}=7.41$.

$\text{C}_{17}\text{H}_{24}\text{O}_8$ requires $\text{C}=57.0$; $\text{H}=7.3$ per cent.

The ester was treated with two atomic proportions of sodium dissolved in alcohol, but was recovered unchanged.

CXXLVII.—*The Chemistry of the Glutaconic Acids.*
Part I. Methods for the Preparation of the
Alkylglutaconic Acids which Prove the Identity of
the α - and γ -Positions in the Glutaconic Acid
*Molecule.**

By FERDINAND BERNARD THOLE and JOCELYN FIELD THORPE.

SOME years ago one of us, in conjunction with H. Rogerson (*Trans.*, 1905, **87**, 1669, 1685), published a new method by which alkyl derivatives of glutaconic acid, having a methyl group in the β -position, and any desired alkyl group in either the α - or γ -position, or in both of these, could be prepared in quantity. The method involved the condensation of the sodium derivative of ethyl cyanacetate with ethyl acetoacetate, when a reaction occurred which is expressed by the equation:

By heating this sodium derivative, or, better, the potassium compound, with alkyl iodides, the corresponding alkyl derivatives were produced, and these, when further treated with sodium hydride and an alkyl iodide, yielded the trialkylated esters, thus:

An important feature of this reaction is that the hydrogen of a complex $\text{CH}\cdot\text{CO}_2\text{Et}$, which is present in the dialkylated ester, is readily displaced by sodium. This is contrary to the conclusion arrived at by Blaise (*Bull. Soc. chim.*, 1903, [iii], **29**, 1016; *Compt. rend.*, 1903, **136**, 381, 692, 1140), who found that only those

* For the abstract of this paper see *Proc.*, 1911, **27**, 122.

derivatives of glutaconic ester which contain the complex $\cdot\text{C}\cdot\text{CHX}$ react with sodium ethoxide. Now it is certain that compounds having this structure react in this manner, a fact which is clearly proved, not only by the work of Henrich (*Monatsh.*, 1899, 20, 55), who discovered this reaction by preparing $\alpha\alpha$ -dimethylglutaconate from the product of the methylation of ethyl glutaconate,

but also by the subsequent work of Perkin and Smith (*Trans.* 1903, 83, 8) and of Blaise (*loc. cit.*). It is, however, also certain that the property of this complex of yielding a sodium compound is entirely determined by the tendency of the mobile hydrogen atom present in the glutaconic acid derivative to pass outside the three-carbon system to the neighbouring carbonyl group. Thus the sodium compounds of this type are always yellow, and there is no doubt that they possess a structure represented by the expression $\cdot\text{C}\cdot\text{C}\cdot\text{C}(\text{ONa})\cdot\text{OEt}$. Abundant proof will be given in this and in the subsequent papers of this series showing that the property of glutaconic acid derivatives of forming compounds of this type diminishes with the increase of alkyl groups in the molecule, and thus the trialkyl derivatives, $\text{CN}\cdot\text{CHMe}\cdot\text{CMe}\cdot\text{CMe}\cdot\text{CO}_2\text{Et}$ and $\text{CO}_2\text{Et}\cdot\text{CHMe}\cdot\text{CMe}\cdot\text{CMe}\cdot\text{CO}_2\text{Et}$, do not form sodium derivatives with sodium ethoxide (*Trans.*, 1905, 87, 1702, 1706). It has also been shown by Feist and Beyer (*Annalen*, 1906, 345, 117) that the introduction of a methyl group into the ester $\text{CO}_2\text{Et}\cdot\text{CHMe}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$ (or $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CMe}\cdot\text{CO}_2\text{Et}$) cannot be effected by the aid of sodium ethoxide and methyl iodide. It therefore follows that in the absence of the mobile hydrogen atom, and possibly, also, owing to the presence of negative groups on the more remote carbon atom, the hydrogen atom of the complex $\cdot\text{CHX}$ is displaceable by sodium, but such sodium compounds are without colour, and presumably have the metal attached to carbon.

The chief proof of the virtual tautomerism of the glutaconic acid molecule advanced in the former paper rested on the structure of two esters (I and II):

(I.)

(II.)

Ester (I) was prepared by the condensation of the potassium compound, to which we assigned the constitution

with methyl iodide. Ester (II) was prepared by the condensation

of ethyl sodiocyanoacetate and ethyl methylacetoacetate. The structure of these two esters was shown to be different by the transformation of (II) into a derivative of dihydroxypyridine by the action of concentrated sulphuric acid, thus:

whereas (I) remained unacted on under the same experimental conditions.

From the fact that esters (I) and (II) yielded the same dimethylglutaconic acid on hydrolysis, it was concluded that the molecule of glutaconic acid is symmetrical, and that the α - and γ -positions in this substance are identical. It was also shown that β -methyl- α -ethylglutaconic acid, $\text{CO}_2\text{H} \cdot \text{CHEt} \cdot \text{CMe} \cdot \text{CH} \cdot \text{CO}_2\text{H}$, and β -methyl- γ -ethylglutaconic acid, $\text{CO}_2\text{H} \cdot \text{CHEt} \cdot \text{CMe} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$, prepared by a similar method were also identical. Since that time the correctness of this conclusion has not been generally accepted, and it has been suggested (Meyer and Jacobson, "Lehrbuch der Organischen Chemie," 1910, 2te Aufl, I, ii, 440) that, during the process of the hydrolysis, the bond must have shifted in either one case or the other, thus yielding the same acid. This point was fully discussed at the time, but was discarded as highly improbable.

It is unfortunate that the real issue, namely, the identity of the α - and γ -positions, should have been masked in the previous paper by the mis-statement that only those derivatives of glutaconic acid which have the mobile hydrogen atom substituted can exist in two modifications. This error was quickly corrected by Feist (*Annalen*, 1906, **345**, 77), who pointed out that β -methylglutaconic acid, $\text{CO}_2\text{H} \cdot \text{CH}_2 \cdot \text{CMe} \cdot \text{CH} \cdot \text{CO}_2\text{H}$, had already been prepared in two well-defined modifications, a fact which had escaped our notice.

Since then, Feist (*Annalen*, 1909, **370**, 41) and Feist and Pomme (*ibid.*, 61) have shown that α -methylglutaconic acid,

can be isolated in two modifications, but that the *cis*-form is relatively unstable. It is therefore evident that, if our view of the constitution of glutaconic acid is correct, the occurrence of stereoisomeric forms must be independent of the mobile hydrogen atom, and it therefore seemed to us desirable to institute a series of experiments on the chemistry of these substances. In the present paper we shall show:

- (1) That the α -alkylglutaconic acids, $\text{CO}_2\text{H} \cdot \text{CHR} \cdot \text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$,

and the γ -alkylglutaconic acids, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CR}\cdot\text{CO}_2\text{H}$, are the same substances, and that α -methyl- γ -ethylglutaconic acid,

and γ -methyl- α -ethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CHEt}\cdot\text{CH}\cdot\text{CMe}\cdot\text{CO}_2\text{H}$ are identical.

(2) That the stability of the *cis*-forms of the α -substituted acids increases with the molecular weight of the substituting group.

It is probable that the cause of the identity of the α - and γ positions is of the same order as that determining the equality of the meta-positions in the benzene ring, and in the ensuing papers we propose to write the formulæ of these substances thus:

indicating the mobile hydrogen atom by means of heavy type; we have retained the older formulæ in the introduction for the sake of clearness.

At the same time it is necessary to offer some explanation respecting the cause of the existence of stereoisomerism among some members of this series, because it is evident that the presence of the mobile hydrogen atom must prevent the occurrence of isomerism corresponding with malic and fumaric acids. The explanation we suggest is as follows: The stereoisomerism of the acids of the type $\text{CO}_2\text{H}\cdot\text{CR}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$, in which the mobile hydrogen atom is displaced, has been clearly established, and there is no doubt that this isomerism is represented by the formulæ

Of the acids containing the mobile hydrogen atom, β -methylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{H}$, exists in two well-defined forms, and Feist has shown that α -methylglutaconic acid $\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$, can be isolated in a *cis*-modification melting at 118° , which is relatively unstable, and can only be formed from the anhydride in the presence of casein. In the present paper we show that *cis*- α -ethylglutaconic acid and *cis*- α -benzylglutaconic acid are stable substances. In spite of numerous attempts we have not yet succeeded in isolating any other of the "mobile" alkylglutaconic acids in two modifications, but we agree with Feist that such forms must be capable of existence, but are difficult to isolate owing to their instability. It is considered that the so-called stereoisomerism of these acids is a reality structural isomerism, and is a property depending on a difference in structure of the carboxyl groups. It is proposed to deal fully with this question in Part IV. of this series, but the terms

and *trans*- are retained in this and the succeeding paper for the sake of clearness.

Preparation of the Alkylglutaconic Acids.

The preparation of alkyl derivatives of glutaconic acids having a methyl group in the β -position has already been described; the preparation in quantity of alkylglutaconic acids having this position unoccupied was a problem which had to be solved.

The α -substituted derivatives can be readily prepared by the alkylation of the yellow sodium compound which Conrad and Guthzeit (*Annalen*, 1883, 222, 259) prepared by the action of chloroform on the sodium compound of ethyl malonate:

but the preparation of further alkylated products is a matter of some difficulty. (For a description of these methods compare Feist, *Annalen*, 1909, 370, 41).

We ultimately devised a method for the preparation of these acids which rests upon an observation recorded in the previous paper (*Trans.*, 1905, 77, 1702), namely, that ethyl α -cyano- $\alpha\beta$ -trimethylglutaconate readily passes into ethyl carbonate and ethyl α -cyano- $\alpha\beta$ -trimethylcrotonate when it is treated with cold sodium ethoxide, thus:

This reaction suggested the general principle that when the mobile hydrogen atoms in compounds of the type of glutaconic ester are all displaced the tendency for the compound to acquire the hydrogen atom necessary for tautomerism is such that the element is at once introduced in the presence of a suitable reagent.

The alkyl derivatives prepared by the action of an alkyl iodide on Conrad and Guthzeit's yellow sodium compound are of this type, and should therefore react with cold sodium ethoxide, thus:

Experiment showed that this reaction proceeded quantitatively, but that in the presence of sodium ethoxide the metal passed to the most negative carbon atom, yielding a sodium compound of the formula *:

* The sodium compounds, which are deep yellow, are written in this form for the sake of clearness, although they have undoubtedly the enolic formulae assigned to them by Heinrich (*Annalen*, 1910, 376, 122).

This was proved by treating the sodium compound, where $R = \text{Me}$, with methyl iodide, when the product on hydrolysis yielded Reformatzky's α -dimethylglutaconic acid,

unaccompanied by any other acid.

The speed of the reaction varies with the value of R ; thus when $R = \text{methyl}$ the change from the tetraethyl to the triethyl ester is complete in the course of an hour at the ordinary temperature. When $R = \text{ethyl}$, two to two and a-half hours are required, and when $R = \text{benzyl}$ the reaction takes at least twelve hours before the transformation is completely effected.

When the above sodium compound is treated with an alkyl iodide the ester $\text{CO}_2\text{Et}\cdot\text{CR}\cdot\text{CH}\cdot\text{CR}(\text{CO}_2\text{Et})_2$ is formed; this is another instance of a glutaconic ester in which the mobile hydrogen atoms are displaced.

It should therefore react with cold sodium ethoxide, thus:

This reaction also proceeds quantitatively, but here again the time varies with the value of R . It is not possible to eliminate more than one carboxy-group from an alkyl derivative of ethyl dicarboxyglutaconate or similarly constituted ethyl ester, even by using two equivalent proportions of sodium ethoxide; thus ethyl α -dicarboxy- α -methylglutaconate when left for several hours in contact with twice the quantity necessary to eliminate α -carboxy-group yields only the triethyl ester, thus:

It is evident that this is caused by the production of the sodium compound, $\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2\cdot\text{C}(\text{ONa})\cdot\text{OEt}$, and the elimination of a further carboxy-group from this substance would not supply the hydrogen atom necessary for virtual tautomerism.

It is therefore necessary in all these reactions to have a molecular proportion of sodium ethoxide present. If, however, the product does not form a sodium derivative, or forms a derivative which is dissociated by alcohol, then the change is effected by the aid of a trace of sodium ethoxide; thus the reaction:

can be brought to completion in the presence of one-tenth the molecular quantity of sodium ethoxide. By this means, therefore, we had at our disposal a method by which any alkyl derivative of glutaconic acid substituted in either the α - or γ -positions or in both of them by any desired alkyl group could be prepared:

quantity, and we then proceeded to gain fresh evidence of the identity of the α - and γ -positions in the glutaconic acid molecule.

The Identity of α - and γ -Alkylglutaconic Acids.

α -Methylglutaconic acid is prepared by the hydrolysis of the ester $(\text{CO}_2\text{Et})_2\text{CMe}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$, and we satisfied ourselves that the same acid, unaccompanied by any other modification, was formed from this ester, both by acid and alkaline hydrolysis.

The action of sodium ethoxide on the ester produces, as already mentioned, a sodium compound of the formula

and the ester prepared from this sodium derivative by the action of acids should on hydrolysis yield γ -methylglutaconic acid,

Both by acid and alkaline hydrolysis the ester yields the already known α -methylglutaconic acid unaccompanied by any other substance. In order to place the identity of these positions beyond question, we prepared the sodium compound:

from which was obtained the already known methylglutaconic acid. It is clear, therefore, that α -methyl- and γ -methylglutaconic acids are the same substance. In the same way it was shown that both β - and γ -ethylglutaconic acids and α - and γ -benzylglutaconic acids, respectively, are identical.

The Identity of α -Methyl- γ -ethylglutaconic Acid and γ -Methyl- α -ethylglutaconic Acid.

γ -Methyl- α -ethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CHEt}\cdot\text{CO}_2\text{H}$, was prepared by the following series of reactions: Ethyl α - γ -dicarboxy- α -methylglutaconate, $(\text{CO}_2\text{Et})_2\text{CMe}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$, was converted into the sodium compound, $\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CNa}(\text{CO}_2\text{Et})_2$, which on ethylation furnished the ethyl derivative,

This ester was hydrolysed (1) through the sodium salt,

and (2) through the compound $\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CHEt}\cdot\text{CO}_2\text{Et}$ (see p. 2192). The methylethylglutaconic acid prepared by these two processes was the same substance; it must therefore be γ -methyl- γ -ethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CHEt}\cdot\text{CO}_2\text{H}$.

α -Methyl- γ -ethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CEt}\cdot\text{CH}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$, was prepared in the following way: The sodium derivative,

on ethylation gave the ethyl compound,

and this on treatment with sodium ethoxide yielded the same compound, $\text{CO}_2\text{Et}\cdot\text{C}(\text{Et})\cdot\text{CH}\cdot\text{CNa}(\text{CO}_2\text{Et})_2$, which on methylation furnished the methyl compound, $\text{CO}_2\text{Et}\cdot\text{C}(\text{Et})\cdot\text{CH}\cdot\text{CMe}(\text{CO}_2\text{Et})_2$.

As in the previous case, this ester was hydrolysed (1) through the sodium salt, $\text{CO}_2\text{Na}\cdot\text{C}(\text{Et})\cdot\text{CH}\cdot\text{CMe}(\text{CO}_2\text{Na})_2$, and (2) through the compound $\text{CO}_2\text{Et}\cdot\text{C}(\text{Et})\cdot\text{CH}\cdot\text{CHMe}\cdot\text{CO}_2\text{Et}$ (see p. 2192). The same acid was produced by both these methods, and it may therefore be α -methyl- γ -ethylglutaconic acid,

γ -Methyl- α -ethylglutaconic acid and α -methyl- γ -ethylglutaconic acid prepared by these methods are the same compound.

During the course of these experiments it has been frequently noticed that the esters of substituted glutaconic acids tend to decompose during alkaline hydrolysis, yielding derivatives of malonic acid. A similar instance of this kind was recorded in a previous paper (Trans., 1905, 87, 1693; compare also *Chem. Annalen*, 1897, 297, 89; Bolam, *Ber.*, 1894, 27, 3061; Gollub, and Bolam, *J. pr. Chem.*, 1896, [ii], 54, 359), when it was found that ethyl α -cyano- β -methylglutaconate,

yielded some malonic acid when hydrolysed by alcoholic potassium hydroxide. In the present paper it is shown that the tendency for esters of this type to undergo fission appears to increase with the molecular weight of the groups present in the molecule, thus the ester $\text{CO}_2\text{Et}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$ is hydrolysed completely to α -methylglutaconic acid, but, under the same conditions, the ester $\text{CO}_2\text{Et}\cdot\text{CHEt}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$ yields a small quantity of ethyl malonic acid, whilst the ester $\text{CO}_2\text{Et}\cdot\text{CH}(\text{CH}_2\text{Ph})\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$ yields benzylmalonic acid, the amount representing about 15 per cent. of the ester hydrolysed. This last reaction recalls the behaviour of benzaldehyde towards potassium hydroxide, and it is possible that the mechanism of these reactions involves the formation of the aldehyde, thus:

It is significant that only those esters which contain a mobile hydrogen atom behave in this manner, and that the corresponding tetracarboxylic esters of the type $(\text{CO}_2\text{Et})_2\text{CR}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$ are hydrolysed directly to the acid without undergoing any disruption. It is of importance to remember this point when preparing the alkyl derivatives of glutaconic acid, because experiment shows that the best yield of acid is obtained from esters containing the mobile

hydrogen atom by hydrolysing them with acid hydrolysing agents. Whereas the esters which have the mobile hydrogen atom displaced are best hydrolysed by alkaline hydroxides.

Guthzeit and Dressel have shown (*Ber.*, 1889, 22, 1415) that when ethyl dicarbethoxyglutaconate is distilled under diminished pressure, alcohol is eliminated and ethyl 6-ethoxy- α -pyrone-3:5-dicarboxylate is formed, thus:

The formation of a pyrone derivative in this manner shows that in a compound of the type of ethyl dicarbethoxyglutaconate there is a considerable tendency for the mobile hydrogen atom to pass outside the three-carbon system, and, as a matter of fact, it is probable that this ester, which gives a marked coloration with ferric chloride, consists largely of the enolic form at the ordinary temperature.

It is shown in this and the succeeding papers that the tendency for the mobile hydrogen atom to pass outside the three-carbon system is mainly determined by the nature of the groups attached to the α -carbon atom, and it is therefore of interest to compare the properties of the corresponding triethyl esters, which also contain the mobile hydrogen atom, as regards their capacity for forming pyrone derivatives; thus ethyl carbethoxy- α -methylglutaconate, $\text{CO}_2\text{Et} \cdot \text{CHMe} \cdot \text{CH} \cdot \text{C}(\text{CO}_2\text{Et})_2$, gives no coloration with ferric chloride, and can be distilled without undergoing change. Ethyl carbethoxy- α -ethylglutaconate, $\text{CO}_2\text{Et} \cdot \text{CHEt} \cdot \text{CH} \cdot \text{C}(\text{CO}_2\text{Et})_2$, also gives no coloration with ferric chloride, and is likewise unaltered on distillation. Ethyl carbethoxy- α -benzylglutaconate,

on the other hand, gives a marked coloration with ferric chloride, and when slowly distilled passes into ethyl 6-ethoxy-3-benzyl- α -pyrone-5-carboxylate, thus:

So far, this is the only triethyl ester of the series which we have succeeded in transforming into the pyrone ring, and it is evident that the presence of a large group attached to the α -carbon atom is necessary in order to displace the mobile hydrogen atom from

the three-carbon system. The dicarboxylic esters of the series are quite unaltered on distillation.

EXPERIMENTAL.

Ethyl α -Dicarbethoxy- α -methylglutaconate, $(\text{CO}_2\text{Et})_2\text{CMe}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$

The methylation of the yellow sodium compound of ethyl dicarbethoxyglutaconate was effected by Conrad and Guthzeit (*Annalen*, 1883, **222**, 259), who employed the action of alcoholic methyl iodide in sealed tubes at a high temperature for this purpose. Ruhemann (*Trans.*, 1893, **63**, 880) found that the presence of alcohol led to unsatisfactory results, and therefore heated the yellow sodium compound to a high temperature with methyl iodide alone. Feist and Pomme (*Annalen*, 1909, **370**, 63), who succeeded in isolating the two stereoisomeric forms of α -methylglutaconic acid, prepared the acid of higher melting point by hydrolysing the above methyl derivative which they prepared by the action of alcoholic methyl sulphate on the yellow sodium derivative.

The first two methods of preparation are tedious, and such as the last-named process is concerned we were quite unable to reproduce the conditions given by Feist and Pomme in their paper. In our hands the action of methyl sulphate yielded hardly 10 per cent. of the methyl derivative, the remainder of the product comprising unaltered ethyl dicarbethoxyglutaconate,* together with ethyl 6-ethoxy- α -pyrone-3:5-dicarboxylate, melting at 94° , a substance which Guthzeit and Dressel (*Ber.*, 1889, **22**, 1415) had prepared previously. Ultimately we found that the best way to prepare ethyl dicarbethoxy- α -methylglutaconate is merely to treat a solution of the yellow sodium compound (50 grams) in alcohol (120 grams) with methyl iodide (30 grams) on the water-bath for five hours. The colourless solution was poured into water and extracted by ether; the ethereal extract, after being washed with water and shaken with a 10 per cent. solution of potassium hydroxide until the extract ceased to be yellow, was dried and evaporated. The residual oil yielded on distillation 40 grams of pure ethyl dicarbethoxy- α -methylglutaconate, boiling at 214° at 21 mm., that is, 83 per cent. of the theoretical amount. (Found: C=55.71; H=7.02. Calc., C=55.8; H=7.0 per cent.)

Hydrolysis.—Ten grams of the ethyl salt were boiled with dilute hydrochloric acid until completely hydrolysed, when the liquid was evaporated to a small bulk and allowed to crystallise. The acid

* The yellow colour of the sodium compound is entirely discharged in this experiment. The reaction is therefore complete.

is best prepared, however, by hydrolysis with an alcoholic solution containing one and a-half times the calculated quantity of potassium hydroxide, when the clear solution of the potassium salt, which evolves carbon dioxide on acidification, yields the pure acid on extraction by ether. Owing to the insolubility of α -methylglutaconic acid in dry ether, the acid separates in a very pure condition when the dried ethereal solution is evaporated to a small bulk. By both these methods the already known α -methylglutaconic acid melting at $145-146^\circ$ was obtained, unaccompanied by any other substance. (Found, C=49.84; H=5.70. Calc., C=50.0; H=5.6 per cent.)

Ethyl Carbethoxy- α -methylglutaconate,
 $\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{C}(\text{CO}_2\text{Et})_2$.

The elimination of one carbethoxy-group from ethyl dicarbethoxy α -methylglutaconate was effected as follows: Forty grams of the tetracetyl ester dissolved in 30 c.c. of alcohol were mixed with a solution containing 2.8 grams of sodium in 32 c.c. of alcohol. The solution became warm and deep yellow, whilst the characteristic odour, which always accompanies the production of ethyl carbonate in these reactions, was at once apparent. After an hour the mixture was poured into dilute hydrochloric acid, and the oil extracted by ether. The ethereal extract after being washed was shaken with a little dilute alkali, dried, and evaporated. The residual oil was then distilled under ordinary pressure until the thermometer registered 140° , when the operation was continued under diminished pressure. The triethyl ester distilled at $182^\circ/2$ mm. as a colourless oil without appreciable odour. Yield, 12 grams, or 93 per cent. of the theoretical:

0.311 gave 0.4838 CO_2 and 0.1505 H_2O . C=57.10; H=7.25.

$\text{C}_{13}\text{H}_{20}\text{O}_6$ requires C=57.3; H=7.4 per cent.

The substance gives no colour with ferric chloride.

The less volatile portion was fractionated under the ordinary pressure, and the large fraction, which boiled at 126° , was characterized as ethyl carbonate by analysis. (Found, C=50.58; H=8.50. Calc., C=50.8; H=8.5 per cent.)

α -Methylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CH}\cdot\text{CO}_2\text{H}$.

Ethyl carbethoxy α -methylglutaconate was subjected to the hydrolysing action of both acids and alkalis in order to prove that α - and γ -methylglutaconic acids were the same substance (compare p. 2193).

Acid Hydrolysis.—The ester was boiled with ten times its bulk of 10 per cent. hydrochloric acid until all had passed into solution, when the product was evaporated to half its volume, and the acid allowed to crystallise. The crude acid melted at 143—146°, and when recrystallised from water melted at 145—146°. The filtrate from the crude acid gave on evaporation an acid which melted at 142—144°, and it is therefore evident that no other substance is formed during the hydrolysis. The acid was proved to be the already known α -methylglutaconic acid by direct comparison with the acid prepared as described on p. 2197.

Alkaline Hydrolysis: Formation of the Sodium Salt,
 $\text{CO}_2\text{Na}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CNa}(\text{CO}_2\text{Na})_2$.

—Twenty-six grams of the ester were added to a solution containing 8.4 grams of sodium dissolved in alcohol, to which 25 c.c. of water had been added. The whole was then warmed on the water-bath, when the yellow solution gradually deposited a white precipitate of the sodium salt. This was collected and washed with alcohol, until quite colourless, when it was spread on a porous plate and dried at 80°:

0.4137 gave 0.4443 Na_2SO_4 . $\text{Na}=33.15$.

$\text{C}_7\text{H}_4\text{O}_6\text{Na}_4$ requires $\text{Na}=33.3$ per cent.

The sodium salt was dissolved in ice-cold water, and cautiously acidified by the addition of the calculated quantity of hydrochloric acid. The strongly alkaline solution which the salt forms with water effervesced freely on the addition of the acid, and when all carbon dioxide had been evolved the solution was extracted by ether. The dried ethereal solution when evaporated yielded a solid acid, which melted at 133—140°. This was then rubbed with dry ether, in which it was very sparingly soluble, and yielded an acid melting at 145—146°. The identity of this acid with α -methylglutaconic acid was proved (1) by a mixed melting-point determination, (2) by the formation of the characteristic chloro-anhydride (see Part II). (Found, $\text{C}=49.88$; $\text{H}=5.68$. Calc., $\text{C}=50.0$; $\text{H}=5.6$ per cent.).

The small quantity of acid which remained on evaporating the ethereal washings from the purification of the above acid melted at 125—133°; when rubbed with a little dry ether this yielded a further quantity of the acid, melting at 145—146°. The ultimate residue, which did not weigh more than 0.5 gram, remained viscid even after some weeks. It possibly contained some of Feist's *cis*-modification melting at 118°, but we were unable to isolate any pure substance from it.

Ethyl α -Dicarbethoxy- α -ethylglutaconate,
 $(\text{CO}_2\text{Et})_2\text{C}(\text{Et})\text{CH}(\text{C}(\text{CO}_2\text{Et})_2)$.

As in the case of the corresponding methyl derivative, we found that by far the best way to prepare this compound is to heat an alcoholic solution of the yellow sodium compound together with excess of ethyl iodide on the water-bath for twenty-four hours. The product was worked up as described for the methyl derivative (p. 2197). The oil obtained boiled at $213^\circ/20$ mm.; yield, 80 per cent. of the theoretical. (Found, C=56.89; H=7.06. Calc., C=57.0; H=7.3 per cent.)

Ethyl Carbethoxy- α -ethylglutaconate,
 $\text{CO}_2\text{Et}\cdot\text{C}(\text{Et})\text{CH}(\text{H})\cdot\text{C}(\text{CO}_2\text{Et})_2$.

This substance was prepared by the action of cold alcoholic sodium ethoxide on ethyl dicarbethoxy- α -ethylglutaconate, but the reaction requires a longer time than is the case with the corresponding methyl derivative.

Thirty-one grams of the ethyl salt dissolved in 25 c.c. of alcohol were added to a solution containing 2 grams of sodium dissolved in 25 c.c. of alcohol. The mixture became warm and deep yellow, but the heat developed was not so great as with the methyl derivative. After three hours at the ordinary temperature the mixture was poured into dilute hydrochloric acid, and the oil extracted by ether. The residual liquid was then fractionated, and the fraction boiling at $180^\circ/20$ mm. collected. Yield, 95 per cent. of the theoretical:

0.2416 gave 0.5170 CO_2 and 0.1649 H_2O . C=58.36; H=7.60.

$\text{C}_{14}\text{H}_{22}\text{O}_6$ requires C=58.7; H=7.0 per cent.

Ethyl Carbethoxy- α -ethylglutaconate is a moderately viscid, colourless liquid without appreciable odour, and does not give a colour with ferric chloride. It was not thought necessary, in this case, to collect the ethyl carbonate formed in the reaction, but its presence was obvious, both from the odour and from the large quantity of material of low boiling point present.

α (or γ)-Ethylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{C}(\text{Et})\text{CH}(\text{H})\cdot\text{CH}\cdot\text{CO}_2\text{H}$.

In the first instance we repeated the work of Guthzeit and Dressel (*Ber.*, 1890, 23, 3182) on the preparation of this acid from ethyl dicarbethoxy- α -ethylglutaconate in order to satisfy ourselves that the same substance was produced by both acid and alkaline hydrolysis. This we found to be the case, but the melting point

of the acid (118—120°) given by the above chemists is much too low; the acid when pure melts at 133—134°.

From Ethyl Carbethoxy- α -ethylglutaconate: Acid Hydrolysis.—The method was the same as that employed in the preparation of α -methylglutaconic acid. The crude acid melted at 128—131°, and when recrystallised from water melted at 133—134°. Some ethyl malonic acid (m. p. 112°) was found in the mother liquor from the hydrolysis. (Found, C=45.2; H=6.08. Calc., C=45.5; H=6.1 per cent.)

Alkaline Hydrolysis.—The process was the same as with α -methylglutaconic acid, and the sodium salt, $\text{CO}_2\text{Na}\cdot\text{CET}\cdot\text{CH}\cdot\text{CNa}(\text{CO}_2\text{Na})$, was obtained. The salt when dissolved in water and acidified with hydrochloric acid yielded on extraction with ether an acid melting at 128—130°, which after recrystallisation from water melted at 133—134°.

0.2294 gave 0.4476 CO_2 and 0.1294 H_2O . C=53.22; H=6.3.
 $\text{C}_7\text{H}_{10}\text{O}_4$ requires C=53.2; H=6.3 per cent.

This form of α -ethylglutaconic acid evidently represents the *trans*-modification corresponding with *trans*- α -methylglutaconic acid melting at 145—146°. An acid of lower melting point which is prepared by the action of potassium hydroxide on the chloroanhydride of the acid will be described in Part II. of this series.

Ethyl α -Dicarbethoxy- α -benzylglutaconate,
 $(\text{CO}_2\text{Et})_2\text{C}(\text{CH}_2\text{Ph})\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$.

The preparation of this substance was carried out in the same manner as that employed for the production of the alkyl derivative already described. The oil boiled at 253°/18 mm., and set to a solid mass on cooling. The melting point of this ester (78°) shows it to be the same substance as prepared by Ruhemann (*Trans* 1893, 63, 259) and by Conrad and Guthzeit (*Annalen*, 1883, 222 261).

Ethyl γ -Carbethoxy- α -benzylglutaconate,
 $\text{CO}_2\text{Et}\cdot\text{C}(\text{CH}_2\text{Ph})\cdot\text{CH}(\text{H})\cdot\text{C}(\text{CO}_2\text{Et})_2$.

Thirty-five grams of ethyl dicarbethoxy- α -benzylglutaconate were dissolved in an equal volume of alcohol and mixed with a solution containing 1.9 grams of sodium dissolved in 25 c.c. of alcohol. The solution, which became deep orange and slightly warm, was kept at the ordinary temperature for twelve hours, when it was poured into dilute hydrochloric acid and the oil extracted by ether. The ethereal extract was then purified in the usual manner, and the oil which remained on evaporation distilled under diminished pressure. Ethyl carbonate, recognisable by its odour, passed over

but was not collected; the triethyl ester then distilled as a colourless, fairly viscous liquid at 218°/22 mm.:

d 2292 gave 0.5494 CO₂ and 0.1448 H₂O. C = 65.37; H = 7.02.

C₁₂H₁₄O₆ requires C = 65.5; H = 6.9 per cent.

An alcoholic solution of ethyl carbethoxy- α -benzylglutaconate gives a reddish-brown colour with ferric chloride.

Ethyl 6-Ethoxy-3-benzyl- α -pyrone-5-carboxylate,

There is always a quantity of material of higher boiling point formed in this reaction, and its presence is evidently caused by the decomposition of ethyl carbethoxy- α -benzylglutaconate during distillation, as when the pure triethyl ester is again distilled a further quantity of the fraction of higher boiling point is obtained. The pure decomposition product boils at 261°/25 mm., and sets to a crystalline mass on cooling. It crystallises from dilute alcohol in voluminous needles melting at 70°:

d 2044 gave 0.5044 CO₂ and 0.1095 H₂O. C = 67.35; H = 5.97.

C₁₇H₁₈O₅ requires C = 67.6; H = 6.0 per cent.

The ester yields α -benzylglutaconate acid on alkaline hydrolysis.

nor- γ -Benzylglutaconic Acid, CO₂H · C(CH₂Ph) · CH(H) · CH · CO₂H.

This acid is the sole product formed by the hydrolysis of ethyl carbethoxy- α -benzylglutaconate by either hydrochloric acid or alcoholic potassium hydroxide. It crystallises from water in clusters of needles melting at 153–154°. (Found, C = 65.40; H = 5.60. Calc., C = 65.5; H = 5.5 per cent.) In order to show the identity of the α - and γ -positions, the same process was adopted as with the α -methyl and α -ethyl acids. In this case, however, the quantity of sodium salt precipitated by the action of alcoholic sodium hydroxide containing a little water was much smaller than would be caused by the conversion of the ester into the sodium salt. When this salt was dissolved in water and acidified, a soluble acid was extracted by ether, which when recrystallised from an equal volume of concentrated hydrochloric acid and water melted at 120°, and was proved to be benzylmalonic acid. (Found, C = 61.67; H = 5.06. Calc., C = 61.9; H = 5.2 per cent. *Silver salt*: Found, Ag = 53.0. Calc., Ag = 53.0 per cent.)

The filtrate from the sodium salt yielded benzylglutaconic acid melting at 153–154°. This acid is probably the *trans*-modification of α -benzylglutaconate acid, as there is an acid of lower melting point which can be prepared from the chloro-anhydride by the action of potassium hydroxide. This substance, which is evidently

the *cis*-modification, crystallises from water in small plates, melting at 139°.

A full description of the preparation and properties of these substances will be found in Part II.

Ethyl Carbethoxy- α - γ -dimethylglutaconate,

This substance was usually prepared by treating the alcoholic solution of the sodium compound formed as described on p. 2157 with 20 per cent. excess of methyl iodide, and warming on the water-bath until the yellow colour of the solution was discharged. The product was then poured into water, and the oil extracted by ether. It was soon evident that the large quantity of methyl iodide used in the experiment had caused a partial conversion of the triethyl ester, and it was found possible by working with large quantities and isolating the first and last runnings from the distillation to obtain the triethyl and methyl diethyl esters in a condition sufficiently pure for analysis. It is, of course, well known that interchange of alkyloxy-groups frequently occurs in reactions of this type, but as it was necessary for our purpose to establish the constitution of our product, we thought it desirable, in one instance, to isolate the two esters and to hydrolyse them separately. With this object in view, 109 grams of ethyl dicarbethoxy- α -methylglutaconate were mixed with 60 c.c. of alcohol, and treated with a solution containing 7.3 grams of sodium dissolved in 90 c.c. of alcohol. After an hour 55 grams of methyl iodide were added and the solution was heated on the water-bath until the yellow colour had disappeared. Water was then added, and the ethyl ester isolated in the usual way.

Methyl Diethyl Carbethoxy- α - γ -dimethylglutaconate.—As soon as all ethyl carbonate had distilled over, the temperature remained constant at 175°/20 mm., and the small fraction collected at this temperature was analysed:

0.2243 gave 0.4719 CO_2 and 0.1519 H_2O . $\text{C}=57.42$; $\text{H}=7.51$.

$\text{C}_{13}\text{H}_{20}\text{O}_6$ requires $\text{C}=57.4$; $\text{H}=7.4$ per cent.

Ethyl Carbethoxy- α - γ -dimethylglutaconate.—The temperature then rose slowly, while the greater portion of the ester distilled over. It finally remained constant at 178°/20 mm., and the small fraction distilling at this temperature was analysed:

0.2397 gave 0.5167 CO_2 and 0.1656 H_2O . $\text{C}=58.78$; $\text{H}=7.67$.

$\text{C}_{14}\text{H}_{22}\text{O}_6$ requires $\text{C}=58.7$; $\text{H}=7.7$ per cent.

The two esters were hydrolysed separately by means of dilute hydrochloric acid, and as in each case α - γ -dimethylglutaconic acid

as obtained as sole product, it is evident that they have the structures assigned to them above.

In the other cases of this kind which occur in this paper it was not thought necessary to isolate the two ethyl esters, and the last instant fraction was always analysed, unless stated otherwise.

Ethyl α -Dimethylglutaconate, $(\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CMe}\cdot\text{CO}_2\text{Et})$.

The conversion of ethyl carbethoxy- α -dimethylglutaconate into ethyl carbonate and the above ester was effected in the following way. Sixty-one grams of the triethyl ester were mixed with 40 c.c. of alcohol, and treated with a cold solution of 4.9 grams of sodium in 50 c.c. of alcohol. The mixture turned yellow after a few seconds, and then became slightly warm; it was kept at the ordinary temperature for one and a-quarter hours, when it was poured into water and extracted by ether without acidifying. The oil obtained on evaporating the dried ethereal solution was distilled under the ordinary pressure until the thermometer registered 135° , when the oil remaining was distilled under diminished pressure. The whole amount distilled between $174\text{--}176^\circ/81$ mm., and the last runnings, constituting the above ester, were analysed:

0.2265 gave 0.4979 CO_2 and 0.1647 H_2O . $\text{C}=59.95$; $\text{H}=8.10$.

$\text{C}_{10}\text{H}_{16}\text{O}_4$ requires $\text{C}=60.0$; $\text{H}=8.0$ per cent.

The large fraction obtained by distilling under ordinary pressure as described above was again distilled, and the fraction boiling at 174° was shown to be ethyl carbonate. (Found, $\text{C}=50.70$; $\text{H}=8.36$. Calc. $\text{C}=50.9$; $\text{H}=8.5$ per cent.)

The above conversion under the experimental conditions described was practically quantitative. When it is desired to prepare α -dimethylglutaconic acid in quantity, it is always advisable to hydrolyse the dialkyl rather than the triethyl ester. It was found that the tertiary esters of the type

are only very slowly hydrolysed by dilute hydrochloric acid, whereas the "mobile" ethyl esters, $\text{CO}_2\text{R}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CMe}\cdot\text{CO}_2\text{R}$, are rapidly converted into the acid under the same conditions.

α -Dimethylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CMe}\cdot\text{CO}_2\text{H}$.

This acid is obtained in a yield of 90 per cent. of the theory when the dialkyl ester is boiled with ten times its volume of 10 per cent. hydrochloric acid until all oil has passed into solution. The greater proportion of the acid separates when the clear hydrochloric acid solution is cooled, and a further quantity is obtained on evaporating the filtrate to a small bulk.

Forty grams of the dialkyl ester gave in this way 23 grams of acid melting at 145—147°, which separated directly from the hydrochloric acid solution; a further 3 grams, melting at 137—140°, were obtained on evaporating the filtrate. Both products when recrystallised once from dilute hydrochloric acid gave pure α - γ -dimethylglutaconic acid, melting at 147°. (Found, C=53.2, H=6.23. Calc., C=53.2; H=6.3 per cent.)

The constitution of this acid was proved, both by the formation of methylmalonic acid from it on oxidation with alkaline permanganate and by direct comparison with a specimen of α - γ -dimethylglutaconic acid prepared by Reformatsky's method from ethyl β -hydroxy- α -dimethylglutarate,

which was kindly sent us by Professor Feist.

The silver salt is a curdy, white precipitate:

0.4055 gave 0.2338 Ag. Ag=57.74.

$\text{C}_7\text{H}_8\text{O}_4\text{Ag}_2$ requires Ag=58.0 per cent.

This ester may be prepared by treating the sodium derivative obtained by the action of sodium ethoxide on ethyl dicarbethoxy- α -methylglutaconate as described on p. 2197 with ethyl iodide. Forty grams of ethyl dicarboxy- α -methylglutaconate were mixed with 30 grams of alcohol, and a solution containing 3 grams of sodium dissolved in 40 c.c. of alcohol were added. After the mixture had been kept at the ordinary temperature for one hour, 30 grams of ethyl iodide were added, and the solution was heated on the water bath for twelve hours. The pale yellow solution was then poured into water, and the ester isolated in the usual way. The oil when fractionated yielded the usual amount of ethyl carbonate and a constant fraction boiling at 180°/20 mm. Yield, 80 per cent of the theoretical:

0.2018 gave 0.4427 CO_2 and 0.1487 H_2O . C=59.83; H=8.19

$\text{C}_{15}\text{H}_{24}\text{O}_6$ requires C=60.0; H=8.0 per cent.

The fractionation has, however, to be carefully conducted because a small quantity of the diethyl ester is also formed in the reaction. This secondary change is evidently due to the partial dissociation of the sodium compound in solution.

Ethyl α -Methyl- γ -ethylglutaconate,
 $\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CET}\cdot\text{CO}_2\text{Et}_2$

The transformation of ethyl carbethoxy- γ -methyl- α -ethylglutaconate into ethyl carbonate and the above ester was effected in the usual manner: Twenty grams of the ester were dissolved in 10 c.c. of alcohol, and mixed with a solution containing 1.6 grams of sodium dissolved in 20 c.c. of alcohol. The solution, which slowly became yellow and developed a slight amount of heat, was kept at the ordinary temperature for two hours, and then worked up as usual. The oil obtained distilled at $163^\circ/23$ mm.:

$n_D^{20} 1.177$ gave 0.5027 CO_2 and 0.1746 H_2O . C=62.96; H=8.91.

$\text{C}_{12}\text{H}_{20}\text{O}_4$ requires C=63.1; H=8.8 per cent.

The yield of the diethyl ester by this process is almost quantitative. The ethyl carbonate formed in the reaction was refracted under ordinary pressure, and the large fraction boiling at 126° was collected. (Found, C=50.71; H=8.59. Calc., C=50.8; H=8.5 per cent.)

Ethyl Carbethoxy- α -methyl- γ -ethylglutaconate,
 $\text{CO}_2\text{Et}\cdot\text{CET}\cdot\text{CH}\cdot\text{CMe}(\text{CO}_2\text{Et})_2$

The preparation of this substance from ethyl dicarbethoxy- α -ethylglutaconate (see p. 2199) was effected in the following manner: Sixty-two grams of the ester were mixed with 40 c.c. of alcohol, and a solution containing 4 grams of sodium dissolved in 20 c.c. of alcohol was added. After three hours at the ordinary temperature, 30 grams of methyl iodide were added, and the mixture heated on the water-bath for eight hours, by which time the strong yellow colour of the liquid had almost disappeared. The product was then poured into water, and the oil isolated in the usual manner. After the ethyl carbonate had been removed by distillation under ordinary pressure, the residue was fractionated under diminished pressure, and the small fraction boiling at $127^\circ/23$ mm. was collected:

$n_D^{20} 1.247$ gave 0.5078 CO_2 and 0.1654 H_2O . C=59.01; H=7.82.

$\text{C}_{14}\text{H}_{22}\text{O}_6$ requires C=58.7; H=7.7 per cent.

This is therefore the methyl diethyl ester formed as explained on p. 2202. The main bulk of the product distilled between 180° and 183° , the yield of methyl diethyl and triethyl esters representing about 80 per cent. of the theoretical amount.

Ethyl α -Methyl- γ -ethylglutaconate, $\text{CO}_2\text{Et}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CEt}\cdot\text{CO}_2\text{Et}$

Although we have no direct evidence that the ethyl ester prepared by the elimination of a carbethoxyl group from ethyl carbethoxy- γ -methyl- α -ethylglutaconate and ethyl carbethoxy- γ -methyl- γ -ethylglutaconate respectively are the same substance, excepting that they yield the same acid on hydrolysis, yet from the identity of the corresponding acids which we have established in this communication it would be unreasonable to suppose that the ethyl esters of the acids can be different compounds. We have therefore given to the above ethyl ester the same name and formula as that assigned to the ester described on p. 2205. The diethyl ester is prepared from ethyl carbethoxy- α -methyl- γ -ethylglutaconate as follows: Thirty grams of the mixed esters prepared as described above were dissolved in 15 c.c. of alcohol, and treated with a solution containing 2.3 grams of sodium dissolved in 30 c.c. of alcohol. The mixture was kept for three hours at the ordinary temperature, when it was poured into water and extracted by ether without acidifying. After the ethereal solution had been purified in the usual manner, the residual oil was distilled free from ethyl carbonate under ordinary pressure, and the remainder fractionated under diminished pressure. A small portion which distilled first at $160^\circ/21$ mm. was analysed:

0.2111 gave 0.4782 CO_2 and 0.1573 H_2O . $\text{C}=61.77$; $\text{H}=8.30$

$\text{C}_{11}\text{H}_{18}\text{O}_4$ requires $\text{C}=61.7$; $\text{H}=8.4$ per cent.

The liquid was therefore the methyl ethyl ester. The main bulk of the product distilled at $160\text{--}163^\circ/21$ mm., the yield of the mixed esters being practically quantitative.

The ethyl carbonate formed in the reaction was obtained by refractionating the material of low boiling point, the portion boiling at 126° being analysed. (Found, $\text{C}=50.70$; $\text{H}=8.45$. Calc. $\text{C}=50.0$; $\text{H}=8.5$ per cent.)

 α -Methyl- γ -ethylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CEt}\cdot\text{CO}_2\text{H}$

For the sake of convenience we have placed all the experimental relating to this acid under one heading, but in order to show the identity of α -methyl- γ -ethylglutaconic acid and γ -methyl- α -ethylglutaconic acid it was necessary to prepare it by four different processes:

(1) *From Ethyl Carbethoxy- γ -methyl- α -ethylglutaconate by Alkaline Hydrolysis.*—Ten grams of the ester were added to an alcoholic solution containing 2.3 grams of sodium in 40 c.c. of alcohol, to which 5 c.c. of water had been added. A gelatinous

sodium salt slowly separated when the solution was warmed on the water-bath, and was collected. The salt was then thoroughly mixed with cold alcohol and again collected, this process being repeated three times. The salt still retained its gelatinous nature, but in spite of that was quite easy to filter; it was spread on a porous plate, and dried at 80° , when it was obtained as a fine, white powder:

0.3143 gave 0.2358 Na_2SO_4 . $\text{Na}=24.31$.

$\text{C}_8\text{H}_9\text{O}_6\text{Na}_3$ requires $\text{Na}=24.5$ per cent.

This substance was therefore the sodium salt,

The Acid from the Sodium Salt.—The salt was dissolved in a little ice-cold water, and the clear solution cautiously acidified by the addition of the calculated quantity of hydrochloric acid, when a vigorous evolution of carbon dioxide ensued. The solution, which had become turbid owing to the separation of the acid as an oil, was extracted by ether, and the ethereal extract dried and evaporated. The residual gum was then dissolved in a little water, and the acid allowed to crystallise. It melted at $114-115^{\circ}$, and after being recrystallised from water, at 116° .

(2) *From Ethyl γ -Methyl- α -ethylglutamate by Acid Hydrolysis.* Ten grams of the ester were mixed with ten times its volume of 10 per cent. hydrochloric acid, and heated on the sand-bath until all oil had passed into solution. The acid separated as a gum when the hydrochloric acid solution was cooled, but when the liquid was scratched with a crystal of the acid obtained in the previous experiment while still warm, the acid separated in the crystalline condition. The crude product melted at $113-115^{\circ}$, and, after being recrystallised from water, at 116° . The identity of this acid with that obtained in the first experiment was established by direct comparison:

0.2105 gave 0.4297 CO_2 and 0.1366 H_2O . $\text{C}=55.67$; $\text{H}=7.22$.

$\text{C}_8\text{H}_{12}\text{O}_4$ requires $\text{C}=55.8$; $\text{H}=7.0$ per cent.

(3) *From Ethyl Carbethoxy- α -methyl- γ -ethylglutamate by Alkaline Hydrolysis.*—The conditions of this experiment were essentially the same as those described in experiment (1), and a similar salt was obtained:

0.3040 gave 0.2289 Na_2SO_4 . $\text{Na}=24.39$.

$\text{C}_8\text{H}_9\text{O}_6\text{Na}_3$ requires $\text{Na}=24.5$ per cent.

This substance was therefore the sodium salt,

Conversion into the Acid.—The salt was dissolved in a little ice-cold water, and the clear solution cautiously acidified by the

addition of the calculated quantity of hydrochloric acid. A vigorous evolution of carbon dioxide took place, and the solution became turbid owing to the separation of the acid, which melted at 115° , after having been once recrystallised from water.

(4) *From Ethyl α -Methyl- γ -ethylglutaconate by Acid Hydrolysis.*—The same conditions as in experiment (2) were observed, and the acid melting at 116° was obtained. A direct comparison of this acid with that obtained in experiment (3) showed them to be the same substance:

0.2336 gave 0.4788 CO_2 and 0.1456 H_2O . $\text{C} = 55.89$; $\text{H} = 6.94$;

$\text{C}_8\text{H}_{12}\text{O}_4$ requires $\text{C} = 55.8$; $\text{H} = 7.0$ per cent.

The identity of the four acids obtained by the processes was established by the mixed melting-point method, and by the conversion of each product into the hydroxy-anil described below. The acid crystallises from benzene in small needles; the crystals from water are not well defined.

The Hydroxy-anil of α -Methyl- γ -ethylglutaconic Acid. A description of the aniline derivatives of α -methyl- γ -ethylglutaconic acid will be given in a future communication, but it is necessary here to give a brief account of the preparation of this anil, as its production was used as a means of identifying the acids prepared by the methods given above. It is formed when the acid is boiled with excess of aniline for two hours, and can be isolated by pouring the product into dilute hydrochloric acid, extracting the insoluble oil by means of ether, and shaking the ethereal solution with aqueous sodium carbonate. The oil which separates when the alkaline washings are acidified slowly becomes solid, and crystallises from dilute alcohol in long needles, melting at 92° .

THE SORBY RESEARCH LABORATORY,
THE UNIVERSITY, SHEFFIELD.

CCXLVIII.—*The Chemistry of the Glutaconic Acids.* *Part II. The Reactions of the Alkylglutaconic Acids Having one Mobile Hydrogen Atom.*

By FERDINAND BERNARD THOLE and JOCELYN FIELD THORPE

FOR the purposes of the present papers we have divided the acids of the glutaconic acid series into three classes, namely:

Class I.—Containing those alkyl derivatives in which there is no mobile hydrogen atom, or, in other words, those compounds in which both hydrogen atoms attached to the α -carbon atom are

displaced. A typical member of this class is $\alpha\alpha$ -dimethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CMe}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$.

Class II.—Containing those alkyl derivatives in which there is one mobile hydrogen atom, that is to say, those in which one hydrogen atom of the methylene group is displaced by an alkyl radicle, as in α -methylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$, or, as we prefer to write the formula, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CH}\cdot\text{CO}_2\text{H}$.

Class III.—Containing those compounds in which both hydrogen atoms of the methylene group are free, as in glutaconic acid itself, and the β monoalkyl derivatives, such as β -methylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{H}$ or $\text{CO}_2\text{H}\cdot\text{CH}\cdot\text{CMe}(\text{H})\cdot\text{CH}\cdot\text{CO}_2\text{H}$.

As regards a compound falling within class I, the fixing of the double bond causes it to exhibit all the properties of a maleic or fumaric acid, and to exist in well-defined *cis*- and *trans*-modifications, which may be represented by the formulæ:

The known acids of this class may be summarised as follows:

	<i>trans.</i>	<i>cis.</i>	Anhydride.	Semi-anilide
$\alpha\alpha$ -Dimethylglutaconic acid,* $\text{CO}_2\text{H}\cdot\text{CMe}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$	172°	134°–135	liquid	164°
$\alpha\beta$ -Trimethylglutaconic acid,† $\text{CO}_2\text{H}\cdot\text{CMe}_2\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{H}$	148	133	107°	138
$\alpha\gamma$ -Trimethylglutaconic acid,‡ $\text{CO}_2\text{H}\cdot\text{CMe}_2\cdot\text{CH}\cdot\text{CMe}\cdot\text{CO}_2\text{H}$	150	125	88	—

* Perkin and Smith (Trans., 1903, 83, 8); Heinrich (Monatsh., 1899, 20, 560); Perkin (Trans., 1902, 81, 253); Blaise (Compt. rend., 1903, 136, 381, 602).

† Perkin and Thorpe (Trans., 1897, 71, 1182); Perkin and Smith (Trans., 1903, 83, 774).

‡ Perkin and Smith (Trans., 1903, 83, 771; 1904, 85, 155).

So far, therefore, as the reactions of the mobile hydrogen atom are concerned, these compounds are without interest, as their reactions are in all respects normal. It is only with the members of classes II and III that the remarkable properties which we shall show are associated with the presence of the mobile hydrogen atom are in evidence; it is therefore with some of the acids of class II that we propose to deal in the present section, reserving a description of other acids for subsequent parts of this series.

It is apparent that the acids falling within class II may be of three types: (a) the monosubstituted derivatives, as α -methylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$; (b) the disubstituted derivatives, such as $\alpha\beta$ -dimethylglutaconic acid,

and $\alpha\gamma$ -dimethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{CMe}\cdot\text{CO}_2\text{H}$; and

(c) the trisubstituted derivatives, such as $\alpha\beta\gamma$ -trimethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{CMe}\cdot\text{CMe}\cdot\text{CO}_2\text{H}$. In the present paper we propose to deal with these derivatives in the above order.

(a) *The Monosubstituted Derivatives.*—The known acids of this type may be summarised as follows:

α -Methylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$.—This acid has been prepared by Conrad and Guthzeit (*Annalen*, 1883, 222, 259), Ruhemann (*Trans.*, 1893, 63, 880), Smoluchowsky (*Munster*, 1894, 15, 56), and by Feist and Pomme (*Annalen*, 1909, 370, 61). The stable form of the acid is undoubtedly the *trans*-*modification which melts, as found by Feist and Pomme, at $145\text{--}146^\circ$. This is, moreover, the chief form in which the acid is obtained, both by the acid or alkaline hydrolysis of its esters. The last-named investigators were unable to cause the acid to react with acetyl chloride, but prepared an anhydride, melting at 85° , through the agency of phosphorus pentachloride. From this anhydride they prepared a semianilide, melting at 165° , and an unstable *cis*-acid, melting at 118° . They also prepared an anil, melting at 229° , by treating the acid of higher melting point with aniline at 150° .

α -Ethylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CHEt}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$.—This acid has been prepared by Guthzeit and Dressel (*Ber.*, 1890, 23, 318). The melting point is given as $118\text{--}120^\circ$, but, as we have shown in Part I. of this series, this is much too low, and the acid when pure melts at $133\text{--}134^\circ$. No other derivatives of this acid have been described.

α -Benzylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CH}(\text{CH}_2\text{Ph})\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$.—This acid has been prepared by Conrad and Guthzeit (*Annalen*, 1883, 222, 261), Ruhemann (*Trans.*, 1893, 63, 259), Guthzeit and Laska (*J. pr. Chem.*, 1896, [ii], 54, 369), and by Guthzeit and Bolam (*ibid.*, 1898, [ii], 58, 428). We find the melting point to be $153\text{--}154^\circ$, which is a little higher than that previously recorded. No derivatives of this acid seem to have been described.

We have selected these three acids for experiment as being typical of the α -monosubstituted derivatives of glutaconic acid, and the results of our experiments are briefly as follows:

These compounds react with acetyl chloride at the temperature of the boiling reagent, but under these conditions the interaction is slow, and is rarely complete. In sealed tubes at 100° , however, the action is rapid, and after four hours no unchanged acid remains. The product is not the true anhydride, but is a mixture

* The terms *cis*- and *trans*- are used in this paper in connexion with the acids of classes II and III for the sake of convenience pending a discussion of the subject in a subsequent part of the series. For the same reason the older formula for the "mobile" acids are retained in the introduction to this part.

two substances, one of which is the hydroxy-anhydride (I), the other the chloro-anhydride (II):

These compounds are, of course, derivatives of α -pyrone, and are named in the experimental portion of this section, but their close relationship to the substituted glutaconic acid renders it advisable to adopt the names hydroxy-anhydride and chloro-anhydride when referring to them in the introduction.

The proportion in which these substances are formed depends entirely on the time during which the reagent is allowed to react, and on prolonged heating at 100° the chloro-anhydride is the sole product. The mechanism of this abnormal reaction is probably thus: The first action of acetyl chloride produces the normal anhydride, but at the temperature of the reaction the mobile hydrogen atom passes outside the three-carbon system to the neighbouring carbonyl group, where it is slowly attacked by acetyl chloride, yielding the acetyl-anhydride (III). This compound is, however, rapidly converted by the hydrogen chloride formed in the reaction into the chloro-anhydride, thus:

Strong support is given to this view, because in one case (that of α -dimethylglutaconic acid) we were able to isolate the acetyl-anhydride, and to show that it was an intermediate product in the transformation of the hydroxy-anhydride into the chloro-anhydride.

As the behaviour of the derivatives of the three acids is much the same, and is only modified by the presence of the heavier grouping, the general properties of these curious substances can be indicated by referring to the α -benzyl derivatives.

The mixture of the hydroxy-anhydride and chloro-anhydride obtained by heating α -benzylglutaconic acid with acetyl chloride, is readily separated by means of ether:

The hydroxy-anhydride acts as a monobasic acid, and is characterised by giving a crystalline monopotassium salt (IV), which is very soluble in water, and the solution when acidified again yields

the hydroxy-anhydride. These changes can therefore be represented thus:

When the chloro-anhydride is treated with excess of aqueous potassium hydroxide it is ultimately converted into the sparingly soluble potassium salt of the hydroxy-pyrone, from which the hydroxy-anhydride is obtained on acidifying:

When the hydroxy anhydride is warmed with excess of potassium hydroxide, it is slowly converted into the dipotassium salt of the *cis*-acid. This acid melts at 139°, and is completely transformed into the *trans*-modification of the acid * when it is boiled for a few minutes with hydrochloric acid:

When the hydroxy-anhydride is boiled with alcohol it is converted into the acid ester:

The hydroxy-anhydrides and the chloro-anhydrides from the α -methyl and α -ethyl acids behave in an analogous manner, but the stability of the anhydride increases with the weight of the group attached to the α -carbon atom; thus the hydroxy-anhydride from the α -methyl acid is rapidly converted into the salt of the *trans*-acid when it is dissolved in excess of sodium hydrogen carbonate solution at the ordinary temperature, and the titration of this substance has therefore to be effected very quickly, otherwise the figures obtained are too high. The hydroxy-anhydride from the α -ethyl acid is much more stable, and can be titrated without any special precautions; but it is slowly converted into the salt of the *cis*-acid in the presence of excess of sodium hydrogen carbonate solution. The stability of the *cis*-forms of these acids increases with the molecular weight of the group occupying the α -position.

* See footnote, p. 2210.

but the *cis*-form is always produced when the anhydride is hydrolyzed by strong alkali hydroxide or by alkali carbonates in the presence of casein.

In the above description of the hydroxy-anhydrides and chloro-anhydrides it will be noticed that we have assigned to them a constitution in which the substituting group is attached to the carbon atom. It is, of course, obvious that in these substances the double bonds must be fixed, and that the virtual tautomerism of the glutaconic acid ceases when the mobile hydrogen passes outside the three-carbon system. There must, therefore, be two forms of these compounds, which can be represented in the case of the hydroxy-anhydride by the formula V and VI:

We are satisfied that the compounds described by us have a structure represented by formula V, because they yield no trace of a pyruvic acid on oxidation, but give oxalic acid as chief product. It is probable that compounds constituted as in formula VI would give pyruvic acid or a homologue under these conditions.

The normal anhydrides of the α -substituted glutaconic acids are formed, as Feist and Pomme (*loc. cit.*) have shown in the case of the α -methyl acid, by treating the acid with sufficient phosphorus pentachloride to convert it into the monoacid chloride when a reaction ensues, which is represented by the equation:

Under these conditions, therefore, the mobile hydrogen atom remains within the three-carbon system, but we find that these normal anhydrides are without exception converted into the hydroxy-anhydrides on distillation, thus:

The Aniline Derivatives of the α -Substituted Glutaconic Acids.—

Up to the present time the only derivatives of this type which have been described are a semianilide, melting at 165°, which Feist and Pomme prepared from the normal anhydride of α -methylglutaconic acid, and an anil melting at 229°, which the same chemists prepared by heating α -methylglutaconic acid with one molecule of aniline at 150°. We have tried on several occasions to prepare the anil melting at 229°, but we have always obtained a semianilide melting at 189°. We therefore sent a small quantity of α -methylglutaconic acid to Professor Feist and asked him to prepare for us some of his anil. Strangely enough, he also obtained our semianilide melting

at 189°, and it is evident, therefore, that the preparation of the anil depends on conditions which cannot be easily reproduced. During our many experiments with α -methylglutaconic acid we have not as yet succeeded in isolating any aniline derivative having this melting point, and the structure of this substance must therefore remain for the present unsolved. The *trans*-modifications of α -methyl-, α -ethyl-, and α -benzyl-glutaconic acids behave in a precisely similar manner when heated with aniline at 150°, and yield well-defined semianilides, which, since they lose carbon dioxide when heated a few degrees above their melting points, yielding anilides of monobasic acids, are probably constituted in accordance with formula VIII:

The only other formula for a semianilide losing carbon dioxide in this manner would be formula VII. That the semianilides prepared by us have a structure represented by formula VIII is proved by the formation of malonic acid from them on oxidation. It is clear that a compound of formula VII would give the alkyl malonic acid when oxidised.

The *cis*-modifications of the three α -substituted acids also give, on heating with aniline,* the *trans*-modifications of the semianilides identical with those prepared from the *trans*-acids, and it is evident, therefore, that a complete rearrangement to the stable *trans* form occurs at the temperature of the reaction. The *cis*-modifications of the semianilide can, however, be readily prepared from the hydroxy anhydrides by warming them in benzene solution with aniline, thus:

The structure of these substances is clear from the fact that on heating at 150° they are completely transformed into the *trans*-semianilides; thus the α -methyl derivative behaves as follows:

* It is probable, and it is assumed, that these anilic acids represent true maleic and fumaric forms, and that in them the double bond is fixed.

The *cis*-semianilides prepared from the hydroxy-anhydrides are not the same compounds as are obtained from the normal anhydride and aniline; thus the *trans*-semianilide from α -methylglutaconic acid melts at 189°, whilst the *cis*-semianilide from the hydroxy-anhydride melts at 148°. The semianilide formed from the normal anhydride by Feist and Pomme melts at 165°. It is probable that this substance is formed in accordance with the following equation (see p. 2201):

The normal anhydrides of these acids are, however, so difficult to prepare that we have not as yet been able to obtain enough of this semianilide to enable us to study the products formed from it on oxidation.

The derivatives of the α -monosubstituted glutaconic acids may therefore be summarised as follows:

	<i>trans</i> -Form.	<i>cis</i> -Form.	Normal anhydride.	Hydroxy-anhydride.	Chloro-anhydride.	<i>cis</i> -Semianilide.	<i>trans</i> -Semianilide.	Semianilide from normal anhydride.
α -Methylglutaconic acid,								
$\text{CO}_2\text{H} \cdot \text{Me} \cdot \text{CH}(\text{H}) \cdot \text{CH} \cdot \text{CO}_2\text{H}$...	145—146°	118°	85°	74·5°	71°	118°	189°	165°
α -Ethylglutaconic acid,								
$\text{CO}_2\text{H} \cdot \text{Et} \cdot \text{CH}(\text{H}) \cdot \text{CH} \cdot \text{CO}_2\text{H}$...	133—134°	108°	liquid	liquid	39°	121°	170°	149°
					B. p.			
					175°/23.			
α -Benzylglutaconic acid,								
$\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_5 \cdot \text{CH}(\text{H}) \cdot \text{CH} \cdot \text{CO}_2\text{H}$	153—154°	139°	—	90·0°	74°	143°	175°	—

The conclusion to be drawn from these experiments is that the stable form of the α -substituted acid and its derivatives at low temperatures contains the mobile hydrogen atom in the three-carbon system, but that at high temperatures the hydrogen atom passes to the carbonyl oxygen.

(c) *The Disubstituted Derivatives.*—There are four acids of this type known:

$\alpha\beta$ *Dimethylglutaconic acid*, $\text{CO}_2\text{H} \cdot \text{CMe} \cdot \text{CMe}(\text{H}) \cdot \text{CH} \cdot \text{CO}_2\text{H}$, has been prepared by Rogerson and Thorpe (*Trans.*, 1905, **87**, 1696) and by Feist and Beyer (*Annalen*, 1906, **345**, 117). The acid melts at 148°, and gives a liquid anhydride boiling at 163°/15 mm.*; the semianilide prepared from this anhydride melts at 139°.

α *Dimethylglutaconic acid*, $\text{CO}_2\text{H} \cdot \text{CMe} \cdot \text{CH}(\text{H}) \cdot \text{CMe} \cdot \text{CO}_2\text{H}$, was

* Through a clerical error the pressure given in the original paper was 25 mm.

first prepared by Reformatzky (*J. Russ. Phys. Chem. Soc.*, 1898, **30**, 453), and subsequently by Blaise (*Bull. Soc. chim.*, 1903, **29**, 1016; *Compt. rend.*, 1903, **136**, 381, 692, 1140). It has been more recently investigated by Feist and Reuter (*Annalen*, 1909, **370**, 82), but these chemists were unable to cause the acid to react with acetyl chloride.

β-Methyl-α-ethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CET}\cdot\text{CMe}(\text{H})\cdot\text{CH}\cdot\text{CO}_2\text{H}$ has been prepared by Rogerson and Thorpe (*Trans.*, 1905, **87**, 1709). It melts at 164° , gives an anhydride melting at 53° , and a semianilide melting at 129° .

α-Methyl-γ-ethylglutaconic acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}(\text{H})\cdot\text{CET}\cdot\text{CO}_2\text{H}$ is described in Part I. of this series (this vol., p. 2197).

Of these acids we propose here to describe only the $\alpha\beta$ - and $\alpha\gamma$ -dimethyl derivatives, leaving the other acids of this series to be dealt with in a subsequent paper.

It is certainly remarkable that Feist and Reuter should have been unable to cause the $\alpha\gamma$ -dimethyl acid to react with acetyl chloride, because in our hands interaction between these substances proceeded smoothly and rapidly at the temperature of the boiling reagent. The probable cause of this discrepancy has revealed itself during some recent experiments with glutaconic acid. This acid does not react with Kahlbaum's pure acetyl chloride under the conditions given by Buchner (*Ber.*, 1894, **27**, 382), but readily does so with Kahlbaum's "Acetyl chloride II." The presence of traces of phosphorus trichloride or phosphoryl chloride in the less pure reagent presumably acts as a "catalyst."

αβ-Dimethylglutaconic Acid.—This acid is converted into the anhydride when it is heated a few degrees above its melting point. The anhydride is also formed when the acid is heated for from ten to fifteen minutes on the water-bath with acetyl chloride, but under these conditions the product consists for the most part of the hydroxy-anhydride, and is composed entirely of this substance. On the heating with acetyl chloride is continued for one hour. And moreover, the normal anhydride is completely converted into the hydroxy-anhydride on distillation, it is evident that the compound described in the former paper as the normal anhydride must be the hydroxy-anhydride of formula IX. This conclusion was tested by a titration of the anhydride, when figures corresponding with the formation of the salt of the hydroxy-pyrone (X) were obtained:

When the cold neutral solution of the salt is acidified, the hydroxy-anhydride is again precipitated, and at the ordinary

temperature there appears to be little tendency for the mobile hydrogen atom to re-enter the three-carbon system; but this change takes place with great rapidity when the solution is boiled, yielding the sodium hydrogen salt of the original acid*:

If, therefore, the $\alpha\beta$ -dimethyl acid is heated for one hour with acetyl chloride, the product after removing the reagent can be extracted entirely from its solution in ether by aqueous sodium hydrogen carbonate. After heating for six hours a considerable quantity of solid remains dissolved in the ether, and this was proved to be the acetyl-anhydride (XI). No trace of the chloro-anhydride is formed under these conditions:

The acetyl-anhydride is readily hydrolysed to the acid from which it was derived, and its formation clearly indicates the mechanism of the reactions by which the chloro-anhydrides are produced. The chloro-anhydride of the $\alpha\beta$ -dimethyl acid is difficult to prepare, but is obtained in small amount by the prolonged action of acetyl chloride at 100°, and is, moreover, formed when the acetyl anhydride is heated in a sealed tube with a solution of hydrogen chloride in acetic acid. Apart from other considerations the constitution of the acetyl-anhydride* is shown by the formation of acetanilide and the semianilide of $\alpha\beta$ -dimethylglutaconic acid when it is treated with excess of aniline:

α , Dimethylglutaconic Acid.—This acid readily yields the normal anhydride, and it is therefore evident that the presence of a second methyl group attached to the γ -carbon atom has a marked restraining effect on the tendency of the mobile hydrogen atom to remain outside the three-carbon system. The normal

* Incidentally these reactions are clearly another proof of the identity of the α - and γ -positions.

anhydride can be quantitatively converted into the crystalline hydroxy-anhydride by heating:

The hydroxy-anhydride is readily produced when the acid is heated with acetyl chloride at 100°, and at the same time there is formed a small quantity of the chloro-anhydride, melting at 82-83°, which is undoubtedly the same substance as that prepared in small quantity by Feist and Reuter (*Annalen*, 1909, 370, 34) by the action of phosphorus pentachloride on the acid. The formation of the acetyl-anhydride could not be detected, and it is evident that the acetylation, and therefore chlorination, of the hydroxy-anhydride takes place with great difficulty.

The hydroxy-anhydride on titration gives figures closely approximating to those required for the monobasic hydroxy-pyrone, but even at the ordinary temperature the passage of the mobile hydrogen atom into the three-carbon system is very rapid, and the change is complete in the course of a few minutes:

The acid produced is again the only known form of the acid.

The Aniline Derivatives of the Members of Section (b).—The fact that the stable form of the acids of this class form anhydrides with greater ease than the mono- α -substituted derivatives, enables them to form certain interesting derivatives with aniline, a study of which throws considerable light on the properties conferred on these compounds by the presence of the mobile hydrogen atom; for example, the hydroxy-anhydride of $\alpha\beta$ -dimethylglutaconic acid yields a semianilide melting at 139°:

which gives an hydroxy-anil in accordance with the scheme:

The hydroxy-anil behaves in the same manner as the hydroxy-anhydrides, and titrates as a monobasic acid. The neutral solution regenerates the hydroxy-anil when acidified, and it is therefore evident that the change must be represented by the scheme:

We have not yet succeeded in finding the conditions under which this substance is converted into the semianilide or normal anil, that is to say, the conditions which cause the mobile hydrogen atom to pass into the three-carbon system, and it is therefore evident that with the $\alpha\beta$ -disubstituted derivatives the tendency for the mobile hydrogen atom to remain outside the three-carbon system is very considerable. Further experiments on the $\alpha\beta$ -dimethyl acid and on higher members of the series are in progress, but so far we have not been able to prepare the normal anhydride of any of these acids in a pure condition.

With the $\alpha\gamma$ -disubstituted derivatives the attachment of an alkyl group to the γ -carbon atom so far modifies the mobility of the hydrogen atom as to cause both forms to be stable. This decreased mobility, which is indicated by the ready manner in which both the normal and hydroxy-anhydrides can be isolated from $\alpha\gamma$ -dimethylglutaconic acid, causes this acid, in the form of its aniline derivatives, to exhibit properties which may be regarded as typical of a compound belonging to this class, in which a state of equilibrium within the molecule enables either the one form or the other to be capable of isolation, and to be readily convertible the one into the other; thus, when the normal anhydride of $\alpha\gamma$ -dimethylglutaconic acid is treated with aniline, a semianilide is formed, which when heated at 150° passes with loss of water into the hydroxy-anil:

This hydroxy-anil behaves as a monobasic acid, and if the cold neutral solution of the salt is acidified, the unaltered anil is precipitated. If, however, the neutral solution is raised to the boiling point and then acidified, the semianilide (m. p. 166°) is obtained as sole product, showing that at 100° the re-entry of the mobile hydrogen atom into the three-carbon system with fission of

the ring is complete. This change may therefore be represented as follows:

The increased stability of the "normal" forms of these compounds causes them, moreover, to exhibit a further interesting change; thus, when a solution of the hydroxy-anil in excess of alkali is titrated with hydrochloric acid, using phenolphthalein as indicator, a definite end-point is reached corresponding with the formation of the alkali salt of the hydroxy-pyrone. On remaining for a few moments the colour of the indicator returns, showing that the solution has become again alkaline. More acid may then be added when the colour again returns on keeping, and this process may be repeated until finally the solution remains neutral. At this stage a considerable quantity of crystalline material separates; this substance is the true anil of the acid. The filtrate from the crystalline anil yields the hydroxy-anil when acidified, and from the recovered substance more of the anil may be prepared by repeating the above process.

It is probable that this behaviour is due to the dissociation of the alkali salt in neutral solution, and the consequent migration of the mobile hydrogen atom, thus:

There is one point respecting the semianilides of the substituted glutaconic acid which requires a brief explanation. It will be remembered that the semianilide prepared by Feist and Pomeroy from the normal anhydride of α -methylglutaconic acid melts at 165° , and is not the same compound as that prepared by us from the hydroxy-anhydride and aniline, which melts at 148° , and is converted on heating into the *trans*-semianilide, melting at 149° .

On the other hand, the semianilides prepared from the normal anhydride and the hydroxy-anhydride of α -dimethylglutaconic acid and aniline are, as already mentioned, identical. The explanation of this apparent discrepancy is, however, obvious, because it is evident that, whereas there are two possible forms of the hydroxy-anhydride of α -methylglutaconic acid, namely:

there is only one possible modification of the hydroxy-anhydride of α,γ -dimethylglutaconic acid, as also of the hydroxy-anil:

The semianilide which is formed from this hydroxy-anil must therefore have the structure:

Thus, it will be noticed, is the same formula as that which we have assigned to the semianilide prepared by Feist and Pomme (see p. 2215), and it is evident, therefore, that the normal anhydrides behave in the same manner in both cases.

The derivatives of the acids of section (b) may be therefore summarised as follows:

	Normal an- Acid.	Hydroxy- anhydride.	Chloro- anhydride.	Hydroxy- anil.	Semianilide.
α -Dimethylglutaconic acid					
$\text{CO}_2\text{H} \cdot \text{CMe} \cdot \text{CMe} \cdot (\text{H}) \cdot \text{CH} \cdot \text{CO}_2\text{H}$ 146°	—	B. p. 183°/ 25 mm.	liquid 125° B. p. 133°/ 25 mm.	130°	—
α -Trimethylglutaconic acid					
$\text{CO}_2\text{H} \cdot \text{CMe} \cdot \text{CH}(\text{H}) \cdot \text{CMe} \cdot \text{CO}_2\text{H}$ 147	liquid	75	82	83	112 166 174

The Acids of Section (c).—The only acid of this kind which is at present known is $\alpha\beta\gamma$ -trimethylglutaconic acid,

which was prepared by Rogerson and Thorpe (Trans., 1905, 87, 1504). The acid melts at 127°, and gives an anhydride when boiled with acetic anhydride, which melts at 119°. As in the case of the $\alpha\beta$ -dimethyl acid, there is no doubt that this anhydride is the hydroxy-anhydride. The normal anhydride is a liquid, and is formed by the action of boiling acetyl chloride on the acid. The normal anhydride is quite insoluble in aqueous sodium hydrogen carbonate, and when distilled is completely converted into the hydroxy-anhydride:

No trace of the chloro-anhydride or acetyl-anhydride could be detected among the products formed in these reactions. The hydroxy-anhydride exhibits all the properties of the other members of the series; thus, when rapidly titrated it yields figures corresponding with those required for the hydroxy-pyrone, but the

neutral solution of the salt rapidly changes on keeping, yielding the monoalkali salt of the original acid:

The Aniline Derivatives.—The behaviour of the $\alpha\beta\gamma$ -trimethyl acid towards aniline is comparable with that of the $\alpha\gamma$ -dimethyl acid, although it is evident that the presence of the methyl group on the β carbon atom slightly increases the tendency for the mobile hydrogen atom to remain outside the three-carbon system; thus, when either the normal or hydroxy-anhydride is treated with aniline, the same semianilide is formed, and this compound when heated at 150° passes into the hydroxy-anil. The latter is also formed when the acid is heated with one molecular proportion of aniline at 150°. The tendency for the mobile hydrogen atom to pass back into the three-carbon system is, however, clearly shown by the fact that an alkaline solution of the hydroxy-anil slowly passes into the true anil and the semianilide, even at the ordinary temperature, and that the change is quickly completed if the solution is gently warmed. These reactions may therefore be represented in the following way:

The derivatives of this acid which we have prepared are:

	Acid ($\alpha\gamma$ -form)	Normal anhydride	Hydroxy- anhydride	Hydroxy- anil.	Semi- anilide	At.
$\alpha\beta\gamma$ -Trimethylglutaconic Acid						
$\text{CO}_2\text{H} \cdot \text{CMe} \cdot \text{CMe}(\text{H}) \cdot \text{CMe} \cdot \text{CO}_2\text{H}$	127°	Liquid	119°	103°	151°	142°

It is desirable to emphasise the following conclusions which may be drawn from the above experiments:

(1) The tendency for the mobile hydrogen atom to pass to a neighbouring carbonyl group is clearly shown by the α -monosubstituted derivatives of glutaconic acid as soon as ring-formation is effected (and the necessary carbonyl group supplied) by transforming the acids into their anhydrides.

(2) The increase in weight of the group occupying the α -position increases the tendency for the mobile hydrogen atom to remain outside the three-carbon system.

(3) This phenomenon cannot be illustrated by the aniline deriva-

ative of the α -monosubstituted acids, because the *cis*-semianilides are converted into stable *trans*-modifications at a lower temperature than that required to throw the mobile hydrogen atom out of the three-carbon system.

(4) The presence of a methyl group at the β -carbon atom considerably increases the tendency for the mobile hydrogen atom to remain outside the three-carbon system.

(5) The presence of methyl groups at both the α - and γ -carbon atoms increases the tendency for the hydrogen atom to remain within the three-carbon system.

(6) The conditions which tend to throw the mobile hydrogen atom outside the three-carbon system are also the conditions which confer stability on the *cis*-form of the acids.

(7) The less stable *cis*-forms can be prepared from the hydroxy-anhydrides in the presence of excess of strong alkali, as well as by the aid of an "anticatalyst" (casein).

EXPERIMENTAL.

The cis-Forms of the α -Monosubstituted Glutaconic Acids with their Normal Anhydrides, Hydroxy-anhydrides, and Chloro-anhydrides.

cis- α -Methylglutaconic Acid and its Normal Anhydride.—These compounds have been fully described by Feist and Pomme (*Annalen*, 1909, 370, 61).

The Hydroxy-anhydride of α -Methylglutaconic Acid (6-Hydroxy-

This compound may be prepared by the distillation of the normal anhydride under diminished pressure, but is more easily obtained by heating the acid with twice the theoretical quantity of acetyl chloride in a sealed tube at 100° for six hours. The product, after evaporating the excess of acetyl chloride on the water-bath, consists of about equal proportions of the hydroxy-anhydride and the chloro-anhydride, which can be separated by dissolving the mixture in dry ether and shaking the solution with aqueous sodium hydrogen carbonate until the lower layer is alkaline. The deep magenta-red aqueous solution is then quickly acidified, and the oil which separates is extracted by shaking once with ether. The hydroxy-anhydride is purified by distilling the ethereal residue under diminished pressure. It may also be obtained free from the chloro-anhydride by boiling the acid with excess of acetic anhydride for two hours and distilling the product, but in this case the formation of highly-coloured by-products considerably diminishes the yield.

The hydroxy-anhydride boils at 167°/18 mm. as a colourless oil, which solidifies on cooling. It crystallises from benzene in long prisms, melting at 74·5°:

0·1570 gave 0·3260 CO₂ and 0·0655 H₂O. C=56·78; H=4·65
C₆H₆O₃ requires C=57·1; H=4·7 per cent.

The hydroxy-anhydride is sparingly soluble in cold water, but dissolves on warming, yielding a solution from which the anhydride partly separates on cooling. It is, however, slowly converted by warm water into the *trans*-form of the α -methyl acid. It dissolves in sodium hydrogen carbonate solution with effervescence, yielding the monoalkali salt of the hydroxy-pyrone, but at the same time a partial change into the dialkali salt of the normal acid ensues, a fact which is clearly shown by the following titration, in which the anhydride was dissolved in excess of standard alkali and titrated back by hydrochloric acid:

0·1902 required 36·6 c.c. of NaOH solution (1 c.c.=0·0017 N_{NaOH}) for complete neutralisation. C₆H₆O₃ (monobasic) requires 35·34 c.c.*

The amount of alkali required for neutralisation increases with the time the alkaline solution of the salt is kept, and it is therefore evident that the change to the dialkali salt of the normal acid takes place fairly rapidly at the ordinary temperature. The neutral solution of the alkali salt of the hydroxy-pyrone formed in the above titration exhibits the characteristic property of all these substances of slowly developing a deep blue colour on keeping. This colour gradually changes through purple to red, and finally the solution becomes yellow. The silver salt of the monobasic acid prepared through the ammonium salt, blackens almost at once.

The pure *cis*-form can be prepared by dissolving the anhydride in strong aqueous alkali, or by employing the "casein" method of Feist (compare *Annalen*, 1909, 370, 52).

Oxidation.—The hydroxy-anhydride was oxidised in ice-cold alkaline solution by means of the requisite amount of permanganate. Oxalic acid was the only product which could be isolated.

The Chloro-anhydride of α -Methylglutaconic Acid (6-Chloro

The preparation of this compound has been partly described in the preceding section, since it remains in the ethereal solution after

* Better numbers can be obtained by dissolving the hydroxy-anhydride in cold alcohol and rapidly titrating with alkali direct; thus, 0·1712 required 31·9 c.c. of NaOH (1 c.c.=0·0017 N_{NaOH}); C₆H₆O₃ requires 31·8 c.c. (monobasic).

all the acid constituents have been extracted by alkali. It is also produced in considerable quantities when the α -methyl acid is boiled with excess of acetyl chloride on the water-bath for four hours. In this case, however, some normal anhydride accompanies the halogen derivative, but owing to the ease with which the latter substance crystallises, it can be readily isolated in a pure condition by spreading on a porous plate. The chloro-anhydride distils without decomposition at $130^{\circ}/25$ mm., and the distillate sets to a solid mass on cooling. It shows a most marked tendency to crystallise, and can be obtained from light petroleum (b. p. $50-60^{\circ}$) in long, colourless prisms, melting at 71° :

0.2351 gave 0.4285 CO_2 and 0.0728 H_2O . $\text{C}=49.70$; $\text{H}=3.45$.

0.2344 " 0.2330 AgCl . $\text{Cl}=24.58$.

$\text{C}_6\text{H}_7\text{O}_2\text{Cl}$ requires $\text{C}=49.8$; $\text{H}=3.5$; $\text{Cl}=24.6$ per cent.

The chloro-anhydride is readily soluble in benzene, and can be distilled under the ordinary pressure without decomposition. It is remarkably stable towards boiling water, and a small quantity separates unchanged when the hot aqueous solution is cooled. It is readily volatile with steam, but is slowly hydrolysed by boiling water and more quickly by aqueous alkalis.

Owing to the hydrogen chloride generated in the former process the acid produced is entirely the *trans*-modification, but in the presence of excess of strong alkali the *cis*-form is alone obtained. The action of excess of aniline on the chloro-anhydride in benzene solution yields a precipitate of aniline hydrochloride. The residue obtained on evaporating the filtered benzene solution gives a solid substance when rubbed with dilute hydrochloric acid, which crystallises from dilute alcohol in small, colourless needles, melting at 158° :

The compound is insoluble in aqueous alkaline carbonates, and would therefore appear to be the *anilide* of the acid,

0.1216 gave 0.3252 CO_2 and 0.0713 H_2O . $\text{C}=73.04$; $\text{H}=6.54$.

$\text{C}_{18}\text{H}_{18}\text{O}_2\text{N}_2$ requires $\text{C}=73.5$; $\text{H}=6.1$ per cent.

The action of aniline on the chloro-anhydride under other conditions will be described in a future communication.

cis- α -Ethylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CET}\cdot\text{CH}(\text{H})\cdot\text{CH}\cdot\text{CO}_2\text{H}$.

Since this acid is much more stable than the corresponding *trans*-modification of α -methylglutaconic acid, it can be readily prepared either from the chloro-anhydride and aqueous potassium hydroxide or from the hydroxy-anhydride with the same reagent, but in this case also the presence of hydrochloric acid causes a

complete conversion of the *cis*- into the *trans*-modifications, and when therefore the chloro-anhydride is boiled with water or when it is left for a long time in contact with moist air, the *trans*-form of the acid melting at 133—134° is alone formed. The *cis*-acid is best prepared in quantity by dissolving the hydroxy-anhydride in excess of strong alkali, adding *N*-hydrochloric acid until neutral, and then warming the solution on the water-bath for a few minutes until a test portion gives no precipitate of unaltered hydroxy-anhydride on the addition of acid. The solution is then acidified when quite cold, and extracted by ether. The acid crystallises from chloroform in small prisms, melting at 108°:

0.2091 gave 0.4055 CO₂ and 0.1148 H₂O. C=52.90; H=6.12

C₇H₁₀O₄ requires C=53.2; H=6.3 per cent.

The silver salt is a white, curdy precipitate:

0.2571 gave 0.1492 Ag. Ag=58.03.

C₇H₈O₄Ag₂ requires Ag=58.06 per cent.

The *cis*-acid is fairly stable towards hydrochloric acid unless the mineral acid is generated *in situ*, as is the case when the chloro-anhydride is treated with water. It can be recrystallised from equal proportions of concentrated hydrochloric acid and water, but if boiled for some time with this mixture gradual conversion of the *cis*- into the *trans*-form ensues, and the change is usually complete after heating for thirty minutes. The acid is very stable toward alkalis, and it may be boiled for a considerable time with excess of alkali hydroxide without undergoing change.

The Normal Anhydride of cis-α-Ethylglutaconic Acid,

An attempt to prepare this substance by the action of acetyl chloride on the *cis*-acid yielded the hydroxy-anhydride as sole product. Ultimately the normal anhydride was prepared in small quantity by the action of phosphorus pentachloride on the *trans*-acid, the conditions employed being the same as those used by Feist and Pomme (*Annalen*, 1909, 370, 69) for the preparation of the normal anhydride from *trans*-α-methylglutaconic acid. The anhydride is a liquid, insoluble in aqueous sodium hydrogen carbonate, and is completely converted into the hydroxy-anhydride on distillation under diminished pressure. It is therefore a matter of some difficulty to obtain this substance in a pure condition, but the following analysis was made of a specimen which had been purified by dissolving in ether and washing with sodium hydrogen carbonate solution:

0.1917 gave 0.4181 CO_2 and 0.1025 H_2O . $\text{C}=59.49$; $\text{H}=5.94$.
 $\text{C}_7\text{H}_5\text{O}_3$ requires $\text{C}=60.0$; $\text{H}=5.7$ per cent.

The Hydroxy-anhydride of α -Ethylglutaconic Acid (6-Hydroxy-3-ethyl- α -pyrone), $\text{CH} \begin{smallmatrix} \text{CEt} \text{---} \text{CO} \\ \text{CH:C(OH)} \end{smallmatrix} \text{O}$.

This compound is obtained, accompanied by the chloro-anhydride, by heating either the *cis*- or the *trans*-acid with twice the theoretical quantity of acetyl chloride in a sealed tube at 100° for six hours. The separation may be effected by evaporating the excess of chloride on the water-bath, dissolving the residue in pure ether, and shaking with aqueous sodium hydrogen carbonate until the lower layer is alkaline. The deep red alkaline solution deposits the anhydride as an oil when it is acidified, and this is then extracted by shaking once with ether. Some *cis*-acid, formed by the action of the alkali on the anhydride, is always extracted by this method, and it is therefore necessary to dissolve the ethereal residue in benzene, in which the *cis*-acid is quite insoluble, and filter in order to obtain the hydroxy-anhydride pure.

The anhydride distils as a mobile liquid at $176^\circ/23$ mm., and dissolves in aqueous sodium hydrogen carbonate with effervescence:

0.2513 gave 0.5052 CO_2 and 0.1146 H_2O . $\text{C}=59.52$; $\text{H}=5.52$.

$\text{C}_7\text{H}_5\text{O}_3$ requires $\text{C}=60.0$; $\text{H}=5.7$ per cent.

0.1540 required 36.8 c.c. of NaOH solution (1 c.c. = 0.001193 gram NaOH) for complete neutralisation. $\text{C}_7\text{H}_5\text{O}_3$ (monohasic) requires 36.9 c.c.

It is evident, therefore, that the tendency for the mobile hydrogen atom to pass back into the three carbon system is less with this compound than with the corresponding methyl derivative; in fact, the hydroxy-anhydride is almost completely recovered when the cold neutral solution is acidified. If, however, the neutral solution is boiled, the change to the mono-alkali salt of the *cis*-acid is rapidly effected. The neutral solution slowly becomes deep blue with violet fluorescence when kept, the colour changing first to red and then to yellow on further keeping. The hydroxy-anhydride is completely converted into the *trans*-acid when boiled with dilute hydrochloric acid.

The Chloro-anhydride of α -Ethylglutaconic Acid (6-Chloro-

3-ethyl- α -pyrone), $\text{CH} \begin{smallmatrix} \text{CEt} \text{---} \text{CO} \\ \text{CH:CCl} \end{smallmatrix} \text{O}$.

The ethereal solution, after extracting the hydroxy-anhydride in the experiment described above, yields the chloro-anhydride on

evaporating. It can also be formed from the *trans*-acid by boiling it with excess of acetyl chloride for four hours, and is isolated in the same manner as in the sealed-tube experiment. By either process the anhydride is obtained as a liquid, which distils at $133^{\circ}/23$ mm. as a colourless oil, solidifying to a mass of crystals on cooling. The solid melts sharply at 39° after being in contact with porous porcelain, but as it is readily soluble in all "inert" solvents it cannot be recrystallised:

0.1890 gave 0.1700 AgCl. Cl = 22.25.

$C_7H_7O_2Cl$ requires Cl = 22.4 per cent.

The chloro-anhydride dissolves slowly in excess of strong alkali hydroxide, the solution becoming warm and red in colour. When all oil has passed into solution the immediate addition of acid causes the separation of an oil free from halogen, which proved on examination to be the pure hydroxy-anhydride.

If the alkaline solution is allowed to remain until no oil is precipitated by acid, ether extracts the *cis*-acid from the acidified solution.

cis- α -Benzylglutaconic Acid, $CO_2H \cdot C(CH_2Ph) \cdot CH(H) \cdot CH \cdot CO_2H$.

This acid is readily prepared, either by dissolving the chloro-anhydride in potassium hydroxide solution and acidifying, or by boiling the hydroxy-anhydride with strong alkali (see p. 2226). In this case also the presence of hydrogen chloride formed in situ causes a complete conversion of the *cis*- into the *trans*-modification and thus when the chloro-anhydride is boiled with water the acid of higher melting point is alone formed. When prepared by either of the above methods, the *cis*-acid separates from water in slender needles, melting at 139° :

0.1826 gave 0.4350 CO_2 and 0.0884 H_2O . C = 65.30; H = 5.39.

$C_{12}H_{12}O_4$ requires C = 65.5; H = 5.5 per cent.

The acid is more soluble in warm water than the *trans*-modification.

The silver salt is a crystalline solid:

0.2941 gave 0.1462 Ag. Ag = 49.71.

$C_{12}H_{10}O_4Ag_2$ requires Ag = 49.77 per cent.

The *cis*-acid is completely converted into the *trans*-modification when boiled for half an hour with concentrated hydrochloric acid. In strong alkaline solution it may be boiled for several hours without undergoing change.

The normal anhydride of α -benzylglutaconic acid could not be prepared. The acid and phosphorus pentachloride react very slowly, and ultimately yields a product containing much chlorine, from which no definite substance could be isolated.

trans Hydroxy-anhydride of α -Benzylglutamic Acid (6-Hydroxy-3-benzyl-a-pyrone), $\text{CH} \begin{smallmatrix} \diagup \text{C}(\text{CH}_2\text{Ph})\cdot\text{CO} \\ \diagdown \text{CH}=\text{C}(\text{OH}) \end{smallmatrix} \text{O}$.

This substance is prepared by heating 5 grams of the *trans* acid with 8 grams of acetyl chloride in a sealed tube at 100° for eight hours. The residue left on evaporating the excess of chloride yields the hydroxy-anhydride as a crystalline solid when rubbed with dry ether. It may be further purified by recrystallisation from a mixture of benzene and light petroleum (b. p. 50 – 60°), when it is obtained in long, flat needles, melting at 90° :

0.1444 gave 0.3748 CO_2 and 0.0634 H_2O . $\text{C}=71.02$; $\text{H}=4.89$.

$\text{C}_{12}\text{H}_{10}\text{O}_3$ requires $\text{C}=71.3$; $\text{H}=5.0$ per cent.

The potassium salt, $\text{CH} \begin{smallmatrix} \diagup \text{C}(\text{CH}_2\text{Ph})\cdot\text{CO} \\ \diagdown \text{CH}=\text{C}(\text{OK}) \end{smallmatrix} \text{O}$, is precipitated in glistening plates when a slight excess of aqueous potassium hydroxide is added to a solution of the hydroxy-anhydride in the same alkali. It crystallises from absolute alcohol in brilliant leaflets:

0.1876 gave 0.0675 K_2SO_4 . $\text{K}=16.13$.

$\text{C}_{12}\text{H}_9\text{O}_3\text{K}$ requires $\text{K}=16.25$ per cent.

The alcoholic filtrate becomes deep blue on keeping.

The following titration of the hydroxy-anhydride was made, the anhydride being dissolved in excess of standard alkali and titrated back with standard acid:

0.2004 required 33.45 c.c. of NaOH solution (1 c.c. = 0.001193 gram NaOH) for neutralisation. $\text{C}_{12}\text{H}_{10}\text{O}_3$ (monobasic) requires 33.26 c.c.

The neutral solution becomes deep blue on keeping. That the cause of this colour is the oxygen of the air is shown by shaking a warm solution of the potassium salt with free access of air, when a deep purple solution is formed, from which a blue precipitate separates on keeping. The dried precipitate closely resembles indigo in appearance, but dissolves in alcohol, forming a fine blue solution.

The silver salt is precipitated as a white powder, which blackens immediately, even in red light. A satisfactory analysis could not be obtained.

The hydroxy-anhydride may also be prepared from the chloro-anhydride by warming it with excess of aqueous potassium hydroxide, when the formation of the insoluble potassium salt of the hydroxy-acid enables this change to be easily followed. The stability of the hydroxy-anhydride is very considerable, and it is necessary to heat it with excess of alkali for at least half an hour

before conversion into the alkali salt of the *cis*-acid is complete. The end-point of this change can be easily determined, because the presence of any unaltered "enol" form causes the separation of the insoluble potassium salt when the solution is cooled.

When the hydroxy-anhydride is boiled with alcohol, it is quickly transformed into the acid ester of the dibasic acid; thus with ethyl alcohol, *ethyl hydrogen α -benzylglutaconate*,

is formed, which crystallises from dilute alcohol in slender needles melting at 93° :

0.1096 gave 0.2714 CO_2 and 0.0636 H_2O . $\text{C}=67.53$; $\text{H}=6.46$.

$\text{C}_{14}\text{H}_{16}\text{O}_4$ requires $\text{C}=67.8$; $\text{H}=6.4$ per cent.

Since the acid ester is hydrolysed to the *cis*-acid by potassium hydroxide it probably retains the *cis*-configuration.

When the hydroxy-anhydride is boiled with dilute hydrochloric acid (one part of concentrated hydrochloric acid to one of water) it passes into solution, and a crystalline solid separates on cooling, which melts fairly sharply at 125° . Since this substance behaves on titration as a dibasic acid, it is probably an equilibrium mixture of the *cis*- and *trans*-modifications. Prolonged boiling with the mineral acid yields the *trans*-modification as sole product.

The Chloro-anhydride of α -Benzylglutaconic Acid (6-chloro-

The ethereal solution from the preparation of the hydroxy-anhydride described above contains the chloro-anhydride, together with a small quantity of dissolved hydroxy-anhydride. Separation can be effected by shaking the ethereal solution with dilute aqueous sodium hydrogen carbonate until the lower layer is alkaline. It is necessary to use the alkali dilute, because otherwise the separation of the sodium salt of the hydroxy-pyrone, which like the potassium salt is insoluble in excess of the reagent, causes difficulty in separating the two layers. The deep magenta alkaline washings deposit a further quantity of the hydroxy-anhydride when acidified. The dried ethereal solution leaves an oil on evaporation, which quickly becomes solid. When recrystallised by dissolving in hot light petroleum (b. p. $60\text{--}70^\circ$), and clearing when cooled by the addition of a little chloroform, it is obtained in long, slender needles, melting at 74° :

0.1934 gave 0.1258 AgCl . $\text{Cl}=16.09$.

$\text{C}_{12}\text{H}_9\text{O}_2\text{Cl}$ requires $\text{Cl}=16.09$ per cent.

The chloro-anhydride is readily soluble in benzene or chloroform

When treated with strong aqueous potassium hydroxide, heat is generated, and the anhydride slowly passes into solution. At the same time the crystalline potassium salt of the hydroxy-anhydride separates.

The cis- and trans-Semianilides of the α -Monosubstituted Glutaconic Acids.

The trans-Semianilide of α -Methylglutaconic Acid.

Reference has been made in the introduction (p. 2213) to a difference in the result obtained by us and by Feist and Pomme respecting the behaviour of α -methylglutaconic acid towards aniline. The semianilide is produced in quantitative yield when the *trans*-acid, mixed with one molecular proportion of aniline, is heated at 150° for ten minutes, and is isolated by rubbing the product with pure ether. It crystallises from ethyl acetate in needle clusters, which melt at 189° , and lose carbon dioxide at 195° . The semianilide is soluble in aqueous sodium carbonate:

0.267 gave 0.5220 CO_2 and 0.1129 H_2O . C=65.69; H=5.80.

$\text{C}_{12}\text{H}_{13}\text{O}_3\text{N}$ requires C=65.8; H=5.9 per cent.

0.2000 required 33.75 c.c. NaOH solution (1 c.c.=0.001079 gram NaOH) for complete neutralisation. $\text{C}_{12}\text{H}_{13}\text{O}_3\text{N}$ (monobasic) requires 33.86 c.c.

When the semianilide is heated until carbon dioxide has ceased to be evolved, the product is an oil insoluble in alkali. It was purified by dissolving in ether, and washing with dilute alkali. As the residue still showed no signs of solidifying and appeared to decompose on distillation, it was analysed:

0.2051 gave 0.5649 CO_2 and 0.1386 H_2O . C=75.11; H=7.51.

$\text{C}_{11}\text{H}_{13}\text{ON}$ requires C=75.4; H=7.4 per cent.

The numbers closely approximate to those required for the anilide, $\text{CHMe}\cdot\text{CMe}\cdot\text{CO}\cdot\text{NHPh}$.

Oxidation of the Semianilide.—The oxidation was effected by dissolving the acid in sodium hydrogen carbonate solution and adding the calculated quantity of a solution of permanganate. The solution was then filtered, acidified, evaporated to dryness, and extracted in a Soxhlet apparatus with ether.

Malonic acid, melting at 132° , was obtained from the ethereal solution (Found, C=34.42; H=3.88. Calc., C=34.6; H=3.8 per cent.).

The trans-Semianilide of α -Ethylglutaconic Acid,

This substance is prepared in precisely the same manner as the

α -methyl derivative. It crystallises from dilute alcohol in needles, which melt at 170° , giving off carbon dioxide at 180° . The semianilide is soluble in aqueous sodium carbonate:

0.2096 gave 0.5137 CO_2 and 0.1181 H_2O . $\text{C}=66.84$; $\text{H}=6.24$.

$\text{C}_{13}\text{H}_{15}\text{O}_3\text{N}$ requires $\text{C}=66.9$; $\text{H}=6.4$ per cent.

The trans-Semianilide of α -Benzylglutaconic Acid,

—The preparation of this compound is the same as described in the case of the α -methyl derivative. It crystallises from dilute alcohol in small needles, which melt at 175° , and evolve carbon dioxide at 190° :

0.1846 gave 0.4965 CO_2 and 0.0955 H_2O . $\text{C}=73.35$; $\text{H}=5.76$.

$\text{C}_{14}\text{H}_{17}\text{O}_3\text{N}$ requires $\text{C}=73.2$; $\text{H}=5.8$ per cent.

The *cis*-semianilides are prepared by the action of aniline on the hydroxy-anhydrides. They pass into the *trans*-semianilides when heated at 150° .

The cis-Semianilide of α -Methylglutaconic Acid,

—When a solution of the hydroxy-anhydride of α -methylglutaconic acid in benzene is mixed with a benzene solution of the requisite quantity of aniline, heat is generated, and the solution becomes deep magenta-red. At the same time a solid substance separates, which is collected and rubbed with pure ether. The semianilide crystallises from dilute alcohol in slender needles, which melt at 148° , evolving carbon dioxide at a higher temperature:

0.1461 gave 0.3509 CO_2 and 0.0797 H_2O . $\text{C}=65.60$; $\text{H}=6.08$.

$\text{C}_{12}\text{H}_{13}\text{O}_3\text{N}$ requires $\text{C}=65.8$; $\text{H}=5.9$ per cent.

The semianilide is readily soluble in aqueous sodium carbonate. When it is heated at 150° for twenty minutes, transformation into the *trans*-semianilide is complete. The compound may be isolated by rubbing the product with ether.

The cis-Semianilide of α -Ethylglutaconic Acid,

—Since this semianilide is soluble in benzene it does not separate when a benzene solution of the hydroxy-anhydride is mixed with a benzene solution of aniline. It may be isolated, however, by evaporating the solution free from benzene, adding ether, and shaking with aqueous sodium carbonate. The oil which separated on acidifying the alkaline solution set to a solid mass, and was purified by rubbing with dry ether and recrystallising from dilute alcohol. The product obtained in this manner did not melt sharply; it was therefore rubbed with benzene, and filtered from a small quantity

of insoluble material. The residue from the benzene filtrate was then recrystallised from dilute alcohol, and obtained in silky needles, melting at 121°:

0.1428 gave 0.3495 CO_2 and 0.0845 H_2O . $\text{C}=67.01$; $\text{H}=6.59$.

$\text{C}_{13}\text{H}_{15}\text{O}_5\text{N}$ requires $\text{C}=66.9$; $\text{H}=6.4$ per cent.

The portion insoluble in benzene proved to be the *trans*-semianilide melting at 170°, and it is therefore evident that even at the temperature of the water-bath some conversion of the *cis*- into the *trans*-modification had taken place. This change is complete when the *cis*-semianilide is heated at 150° for fifteen minutes.

The Semianilide from the Normal Anhydride of α -Ethylglutaconic Acid, $\text{CO}_2\text{H}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{Et}\cdot\text{CO}\cdot\text{NHPh}$.—This substance is prepared by the action of aniline on the normal anhydride in benzene solution, and is isolated by extracting the ethereal solution of the residue with aqueous sodium carbonate. It crystallises from dilute alcohol in small plates, melting at 149°:

0.1499 gave 0.3666 CO_2 and 0.0884 H_2O . $\text{C}=66.75$; $\text{H}=6.55$.

$\text{C}_{13}\text{H}_{15}\text{O}_5\text{N}$ requires $\text{C}=66.9$; $\text{H}=6.4$ per cent.

The cis-Semianilide of α -Benzylglutaconic Acid,
 $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}\cdot\text{C}(\text{CH}_2\text{Ph})\cdot\text{CO}\cdot\text{NHPh}$.

In this case the semianilide separates when benzene solutions of the hydroxy-anhydride and aniline are mixed. It crystallises from dilute alcohol in long, slender needles, melting at 143°. The semianilide dissolves in aqueous sodium carbonate, but if the alkali is strong an oily sodium salt is precipitated, which, however, dissolves when water is added:

0.2042 gave 0.5451 CO_2 and 0.1022 H_2O . $\text{C}=73.00$; $\text{H}=5.57$.

$\text{C}_{13}\text{H}_{17}\text{O}_5\text{N}$ requires $\text{C}=73.2$; $\text{H}=5.8$ per cent.

The *cis*-semianilide is completely converted into the *trans*-semianilide, melting at 175°, when heated at 150° for fifteen minutes.

The Normal Anhydrides, Hydroxy-anhydrides, and Chloro-anhydrides of the Disubstituted Glutaconic Acids.

$\alpha\beta$ -Dimethylglutaconic Acid.—We have been unable to prepare the normal anhydride of this acid. The tendency for the mobile hydrogen atom to pass outside the three-carbon system is so considerable that even when dehydration is effected at low temperatures the hydroxy-anhydride is alone formed.

The Hydroxy-anhydride of αβ-Dimethylglutaconic Acid (6-Hydroxy,

This substance is formed by the action of boiling acetyl chloride on the acid, and was described in a former communication (Trans. 1905, 87, 1696) as the normal anhydride. It is a mobile liquid which boils at 183°/25 mm. (through a misprint the boiling point was wrongly given in the original paper):

0.1629 required 38.9 c.c. of NaOH solution (1 c.c. = 0.001193 gram NaOH) for complete neutralisation. $\text{C}_7\text{H}_8\text{O}_3$ (monobasic) requires 39.0 c.c.

The hydroxy-anhydride is precipitated by adding acid to a solution of the anhydride in alkali, and the change into the alkali salt of the dibasic acid is very slow at the ordinary temperature. The acid formed is the same as that from which the anhydride was derived. The neutral solution from the above titration becomes deep purple on keeping, and it is evident that the property of forming coloured solution in this manner is characteristic of α hydroxy-anhydrides.

The Acetyl-anhydride of αβ-Dimethylglutaconic Acid (6-Acetoxy,

It is possible to isolate this substance in a pure condition because there is no tendency whatever for the production of the chloro-anhydride when the acid is heated with acetyl chloride at the temperature of the boiling reagent. The acid is heated with a large excess of acetyl chloride for six hours on the water-bath, and the excess of the chloride is then evaporated. The neutral acetyl-anhydride is separated from the hydroxy-anhydride by dissolving the residue in ether and shaking with aqueous sodium hydrogencarbonate, and is obtained as a crystalline solid when the ethereal solution is evaporated. It crystallises from a mixture of chloroform and light petroleum (b. p. 50—60°) in long, rhombic prisms, melting at 65°:

0.2385 gave 0.5189 CO_2 and 0.1202 H_2O . $\text{C} = 59.33$; $\text{H} = 5.60$
 $\text{C}_9\text{H}_{10}\text{O}_4$ requires $\text{C} = 59.3$; $\text{H} = 5.5$ per cent.

The acetyl-anhydride is readily soluble in benzene or chloroform; it is insoluble in light petroleum. When warmed with aqueous potassium hydroxide it slowly dissolves, and a crystalline potassium salt separates if a sufficient excess of alkali is present. The solution of this salt in water when acidified yields the acid melting at 145°.

The constitution of the acetyl-anhydride was proved by the formation of acetanilide by the action of aniline. The anhydride dissolved in benzene was mixed with a benzene solution containing excess of aniline, and the mixture evaporated free from the solvent. The residue was then dissolved in ether, and shaken, first with sodium carbonate solution and then with dilute hydrochloric acid. Acetanilide (m. p. 115°) was isolated from the ethereal solution on evaporation (Found, C=70.92; H=6.81. Calc., C=71.1; H=6.7 per cent.). When the sodium carbonate washings from the above preparation were acidified, the semianilide melting at 139° (see p. 2218) is precipitated.

The Chloro-anhydride of $\alpha\beta$ -Dimethylglutaconic Acid (6-Chloro-3:4-dimethyl- α -pyrone), $\text{CMe} \begin{smallmatrix} \text{CMe} \cdot \text{CO} \\ \text{CH} : \text{CCl} \end{smallmatrix} \text{O}.$

This substance is prepared in small amount by heating $\alpha\beta$ -dimethylglutaconic acid with twice the theoretical amount of acetyl chloride in a sealed tube at 100° for ten hours, and can be isolated in the same way as the chloro-anhydrides already described. It is a liquid which distils at 133°/26 mm.:

0.2069 gave 0.1872 AgCl. Cl=22.37.

$\text{C}_7\text{H}_7\text{O}_4\text{Cl}$ requires Cl=22.4 per cent.

The chloro-anhydride slowly dissolves when shaken with aqueous potassium hydroxide, and the solution, when acidified and extracted with ether, yields the acid melting at 148°.

The Normal Anhydride of $\alpha\gamma$ -Dimethylglutaconic Acid,

When 5 grams of $\alpha\gamma$ -dimethylglutaconic acid are heated on the water-bath with 40 c.c. of acetyl chloride, a vigorous reaction ensues, and much hydrogen chloride is evolved. The reaction ceases after sixty minutes, and the anhydride can be isolated by evaporating the chloride, dissolving the residue in ether, and shaking the ethereal solution with aqueous sodium hydrogen carbonate. The residue obtained from the ethereal solution on evaporation slowly polymerises to a resin when kept in an evacuated desiccator; as, moreover, it passed into the hydroxy-anhydride (q.v.) and other products on distillation, it was analysed after it had been kept in a vacuum desiccator for two hours. The hydrogen result is therefore rather high, owing to the presence of traces of ether:

0.2290 gave 0.5042 CO_2 and 0.1241 H_2O . C=60.05; H=6.02.

$\text{C}_7\text{H}_8\text{O}_3$ requires C=60.0; H=5.7 per cent.

The anhydride is insoluble in cold aqueous sodium carbonate, but slowly dissolves on warming. The acid melting at 147° is extracted from the acidified solution by ether.

The Hydroxy-anhydride of α -Dimethylglutaconic Acid (6-Hydroxy-3:5-dimethyl- α -pyrone), $\text{CH} \begin{array}{c} \text{CMe}-\text{CO} \\ \text{CMe}:\text{C}(\text{OH}) \end{array} \text{O}.$

The hydroxy-anhydride is readily prepared by heating the normal anhydride at 150° for ten minutes, and can be isolated by dissolving the melted product in ether, and shaking with aqueous sodium hydrogen carbonate. The alkaline solution, if immediately acidified, precipitates the anhydride as an oil, which quickly becomes solid. It is also formed, accompanied by some chloro-anhydride, when α -dimethylglutaconic acid is heated with twice the theoretical amount of acetyl chloride in a sealed tube at 100° for six hours, and can be separated by the method already described. The anhydride distils at $183^{\circ}/27$ mm. as a mobile oil, which solidifies on cooling. It crystallises from a mixture of benzene and light petroleum (b. p. $60-70^{\circ}$) in glistening plates, melting at 75° .

0.2244 gave 0.4922 CO_2 and 0.1144 H_2O . $\text{C}=59.81$; $\text{H}=5.66$.

$\text{C}_7\text{H}_6\text{O}_3$ requires $\text{C}=60.0$; $\text{H}=5.7$ per cent.

The hydroxy-anhydride is readily soluble in benzene, sparingly so in ether, and practically insoluble in light petroleum. It dissolves in aqueous sodium hydrogen carbonate with effervescence, and can be partly recovered if the solution is quickly acidified, but if kept at the ordinary temperature for twenty minutes it is completely converted into the salt of the acid from which it was derived; this can be recovered by extracting the acidified solution with ether.

0.1537 required 36.7 c.c. NaOH solution (1 c.c. = 0.001192 gram NaOH) for complete neutralisation. $\text{C}_7\text{H}_6\text{O}_3$ (monobasic) requires 36.8 c.c.

The usual purple colour is developed when the neutral solution is kept.

The hydroxy-anhydride dissolves when boiled with water, and on cooling a small amount separates unaltered. It is, however, rapidly converted by hot water into α -dimethylglutaconic acid.

The Chloro-anhydride of α -Dimethylglutaconic Acid (6-Chloro-3:5-dimethyl- α -pyrone), $\text{CH} \begin{array}{c} \text{CMe}-\text{CO} \\ \text{CMe}:\text{CCl} \end{array} \text{O}.$

A compound to which the above formula was assigned was prepared by Feist and Reuter (*Annalen*, 1909, **370**, 82) by the action of phosphorus pentachloride on α -dimethylglutaconic acid.

but only in very small quantity. It can be prepared in a yield of about 30 per cent. by heating $\alpha\gamma$ -dimethylglutaconic acid with twice the theoretical quantity of acetyl chloride in a sealed tube at 100° for eight hours, and can be isolated in the usual manner. The compound melts at $82-83^\circ$, as described by Feist and Reuter. (Found, Cl=22.31. Calc., Cl=22.4 per cent.)

The chloro-anhydride slowly dissolves when warmed with aqueous potassium hydroxide, and the solution when acidified and extracted with ether yields $\alpha\gamma$ -dimethylglutaconic acid, melting at 147° .

The Semianilides, Hydroxy-anils, and Anils of the Disubstituted Glutaconic Acids.

The Semianilide of $\alpha\beta$ -Dimethylglutaconic Acid.

This substance, which melts at 139° , was described in a former paper (Trans., 1905, 87, 1697). When heated at 150° it loses water, and is converted into the hydroxy-anil. The same semianilide is formed from the anhydride, both before and after distillation.

The Hydroxy-anil of $\alpha\beta$ -Dimethylglutaconic Acid (3-Hydroxy-2-phenyl-5:6-dimethyl-1:2-dihydropyridone),

This compound can be prepared either by heating the semianilide in the manner described above, or by heating $\alpha\beta$ -dimethylglutaconic acid with one molecular quantity of aniline at 150° for fifteen minutes. In both cases the product is isolated by rubbing with pure ether, in which the hydroxy-anil is insoluble. It crystallises from alcohol in lustrous plates, melting at 125° :

0.1281 gave 0.3391 CO_2 and 0.0707 H_2O . C=72.25; H=6.15.

0.1276 " 0.3383 CO_2 " 0.0675 H_2O . C=72.30; H=5.90.

$\text{C}_{13}\text{H}_{15}\text{O}_2\text{N}$ requires C=72.6; H=6.1 per cent.

0.2367 required 36.5 e.e. of NaOH solution (1 e.e.=0.001072 gram NaOH). $\text{C}_{13}\text{H}_{15}\text{O}_2\text{N}$ (monobasic) requires 36.3 e.e.

The dissociation of the salt of the hydroxy-anil (see p. 2220) causes the neutral solution to become alkaline on keeping, but the further addition of 0.2 e.e. of *N*/10-acid is sufficient to stop this process, and therefore the amount of anil formed is too small to be isolated. The neutral solution of the alkali salt can be boiled for some considerable time without undergoing change, and it is therefore evident that the condition having the mobile hydrogen atom outside the three-carbon system possesses remarkable stability.

The Semianilide of α -Dimethylglutaconic Acid,
 $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CHMe}\cdot\text{CO}\cdot\text{NHPh}.$

—This compound can be prepared either from the normal anhydride or the hydroxy-anhydride by dissolving in benzene and adding a benzene solution containing rather more than the requisite amount of aniline. It can be isolated by evaporating free from the solvent, dissolving in ether, and shaking the ethereal solution with aqueous sodium carbonate. The semianilide separates from dilute alcohol in microscopic needle clusters, melting at $165\text{--}166^\circ$:

0.1883 gave 0.4604 CO_2 and 0.1130 H_2O . $\text{C} = 66.68$; $\text{H} = 6.61$.

$\text{C}_{13}\text{H}_{15}\text{O}_3\text{N}$ requires $\text{C} = 66.9$; $\text{H} = 6.4$ per cent.

When the semianilide is prepared from the hydroxy-anhydride some neutral substance remains in the ethereal solution, which crystallises from alcohol in small needles, melting at 195° , and is probably the anilide of α -dimethylglutaconic acid,

0.2297 gave 0.6215 CO_2 and 0.1337 H_2O . $\text{C} = 73.77$; $\text{H} = 6.49$.

$\text{C}_{19}\text{H}_{20}\text{O}_2\text{N}_2$ requires $\text{C} = 74.0$; $\text{H} = 6.5$ per cent.

When the semianilide is heated at 150° for fifteen minutes it is completely transformed into the hydroxy-anil and water.

The Hydroxy-anil of α -Dimethylglutaconic Acid (3-Hydroxy-2-phenyl-4:6-dimethyl-1:2-dihydropyridone),

After several experiments on the action of aniline on α -dimethylglutaconic acid it was found that the best yield of the hydroxy-anil was obtained by boiling the acid with excess of aniline for one hour. The product can be isolated by pouring the aniline solution into dilute hydrochloric acid, extracting the insoluble oil by ether, and shaking the ethereal solution with aqueous sodium carbonate. It crystallises from dilute alcohol in plates, melting at 112° :

0.2046 gave 0.5425 CO_2 and 0.1107 H_2O . $\text{C} = 72.32$; $\text{H} = 6.61$.

$\text{C}_{13}\text{H}_{13}\text{O}_2\text{N}$ requires $\text{C} = 72.6$; $\text{H} = 6.1$ per cent.

0.1935 required 33.4 c.c. of NaOH solution (1 c.c. = 0.001072 gms NaOH) for neutralisation. $\text{C}_{13}\text{H}_{13}\text{O}_2\text{N}$ (monobasic) requires 33.6 c.c.

The indicator colour of the neutral solution (phenolphthalein) slowly returns on keeping, and it is possible to add 2.3 c.c. of $N/10$ -acid before this process ceases. By using larger quantities the crystalline precipitate which separates from the neutral solution is

* A small quantity of the normal anil is always formed by this method and is removed on crystallisation.

keeping can be collected. It crystallises from alcohol, in which it is sparingly soluble, in small needles, melting at 174° , forming a magenta-red liquid:

0.2025 gave 0.5381 CO_2 and 0.1096 H_2O . $\text{C}=72.48$; $\text{H}=6.02$.

$\text{C}_{13}\text{H}_{15}\text{O}_5\text{N}$ requires $\text{C}=72.6$; $\text{H}=6.1$ per cent.

The compound is therefore the anil of $\alpha\gamma$ -dimethylglutaconic acid,

$\text{CH}(\text{H}) \begin{matrix} \text{CMe}\cdot\text{CO} \\ \diagup \quad \diagdown \\ \text{CMe}\cdot\text{CO} \end{matrix} \text{NPh}$. When a neutral solution of the hydroxy-

anil is acidified, the substance is precipitated unaltered, but if the neutral solution is warmed on the water bath for half an hour and then acidified, the semianilide melting at 165 – 166° is precipitated. The following analysis and titration was made of this product in order to place its identity beyond question. (Found, $\text{C}=66.67$; $\text{H}=6.34$. Calc., $\text{C}=66.9$; $\text{H}=6.5$ per cent.):

0.2004 required 31.9 c.c. of NaOH solution (1 c.c. = 0.001079 gram

NaOH) for neutralisation. $\text{C}_{13}\text{H}_{15}\text{O}_5\text{N}$ requires 31.88 c.c.

The colour of the indicator does not return when the neutral solution is kept. The semianilide is reconverted into the hydroxy-anil when heated at 150° .

The Normal Anhydrides and Hydroxy-anhydrides of the Trisubstituted Glutaconic Acids.

The only acid belonging to this series which we have as yet investigated is $\alpha\beta\gamma$ -trimethylglutaconic acid. (For method of preparation compare *Trans.*, 1905, **87**, 1704.)

The Normal Anhydride of $\alpha\beta\gamma$ -Trimethylglutaconic Acid,

This substance can be prepared by heating the acid with excess of acetyl chloride on the water-bath for one hour, and can be isolated by evaporating the reagent, dissolving the residue in ether, and extracting acid impurities by shaking with aqueous sodium hydrogen carbonate. It is a liquid which passes into the hydroxy-anhydride on distillation. It does not, however, show any tendency to polymerise, and can therefore be purified by placing in an evacuated desiccator for twelve hours:

0.1992 gave 0.4556 CO_2 and 0.1222 H_2O . $\text{C}=62.38$; $\text{H}=6.81$.

$\text{C}_8\text{H}_{10}\text{O}_3$ requires $\text{C}=62.3$; $\text{H}=6.5$ per cent.

The high content of hydrogen can be accounted for by the presence of traces of dissolved ether.

*The Hydroxy-anhydride of αβγ-Trimethylglutaconic Acid
(6-Hydroxy-3:4:5-trimethyl-α-pyrone),*

This compound was described as the normal anhydride in the previous paper (Trans., 1905, 87, 1705). It can be prepared either by the method then given or by heating the normal anhydride at 150° for fifteen minutes. The melting point is 119°, as stated previously. The anhydride is fairly stable in the presence of excess of alkali, but is best titrated directly with alkali in very cold dilute alcoholic solution. The figures are, however, only approximate.

0.1897 required 41.6 c.c. of NaOH solution (1 c.c. = 0.001176 gram NaOH) for neutralisation. $\text{C}_8\text{H}_{10}\text{O}_3$ (monobasic) requires 41.07 c.c.

When the hydroxy-anhydride is dissolved in alkali, no precipitate of unchanged material occurs on the addition of acid, and it is evident that even at the ordinary temperature transformation into the salt of the dibasic acid is fairly rapid. The acid formed either directly or in the presence of casein in accordance with Feist's method is the same acid as that from which the anhydride was derived.

The formation of the chloro-anhydride by the prolonged action of acetyl chloride on αβγ-trimethylglutaconic acid was not observed.

*The Semianilide and Hydroxy-anil of the Trisubstituted
Glutaconic Acid.*

The Semianilide of αβγ-Trimethylglutaconic Acid,

—The same semianilide is prepared both from the normal anhydride and hydroxy-anhydride when they are treated in benzene solution with the requisite amount of aniline dissolved in the same solvent. The product is isolated by evaporating the solvent, and shaking the ethereal solution of the residue with aqueous sodium carbonate. It crystallises from dilute alcohol in slender needles, melting at 151°:

0.2100 gave 0.5223 CO_2 and 0.1317 H_2O . $\text{C} = 67.83$; $\text{H} = 6.97$.

$\text{C}_{14}\text{H}_{17}\text{O}_3\text{N}$ requires $\text{C} = 68.0$; $\text{H} = 6.9$ per cent.

The semianilide is completely converted into the hydroxy-anil when heated at 150° for fifteen minutes. It is readily soluble in benzene or alcohol.

The Hydroxy-anil of αβ-Trimethylglutaconic Acid (3-Hydroxy-2-phenyl-4:5:6-trimethyl-1:2-dihydropyridone),

This compound is best prepared by heating the acid with one molecular quantity of aniline for fifteen minutes at 150°. The product is completely soluble in ether, and therefore the hydroxy-anil must be isolated by shaking the ethereal solution with aqueous sodium carbonate. It crystallises from dilute alcohol in small needles, melting at 103°:

0.1435 gave 0.3834 CO₂ and 0.0824 H₂O. C=73.04; H=6.40.

C₁₄H₁₃O₂N requires C=73.4; H=6.6 per cent.

In this experiment the sodium carbonate extract must be acidified immediately, otherwise some semianilide is formed. The following titration was made by dissolving the hydroxy-anil in dilute alcohol, and titrating direct with alkali:

0.1621 required 24.0 c.c. NaOH solution (1 c.c.=0.001174 gram NaOH) for neutralisation. C₁₄H₁₃O₂N requires 24.1 c.c.

When the neutral solution is warmed and then acidified, the semianilide melting at 151° is precipitated on acidifying.

When the hydroxy-anil is dissolved in excess of cold alkali and the solution is titrated with standard acid until neutral, the colour of the indicator (phenolphthalein) returns on keeping. A small amount of crystalline material is obtained by adding acid until the solution remains neutral. This is the anil of αβ-trimethyl-

glutaconic acid, CMe(H) $\begin{array}{c} \text{CMe} \text{---} \text{CO} \\ \text{CMe} \text{---} \text{CO} \end{array}$ NPh, and separates from alcohol in slender needles, melting at 162°:

0.1562 gave 0.4186 CO₂ and 0.0906 H₂O. C=73.08; H=6.38.

C₁₄H₁₃O₂N requires C=73.4; H=6.6 per cent.

The amount of the anil formed in this manner is very small, as the greater portion of the hydroxy-anil is converted into the semianilide during the course of the experiment.

THE SORBY RESEARCH LABORATORY,
THE UNIVERSITY, SHEFFIELD.

CCXLIX.—*Electromotive Forces in Alcohol. Part II*
The Hydrogen Electrode in Alcohol and the
Influence of Water on its Electromotive Force.

By ROBERT TAYLOR HARDMAN and ARTHUR LAPWORTH.

It is generally stated that the electromotive force obtained when two platinum sheets saturated with hydrogen are immersed in two dilute aqueous solutions, which are in mutual contact, is given by the expression:

$$E = \frac{RT}{F} \log_e \frac{C}{C'},$$

(where C and C' represent the concentrations of the "hydrogen ions" in the two liquids respectively, and E , R , T , and F have their usual significance), provided that there is no potential difference at the liquid boundary, and that there is no substance present which can be reduced by the hydrogen under the experimental conditions.

The quantities C and C' in the foregoing expression properly refer to those hydrions which are characteristic of aqueous solutions of acids rather than to the "free" hydrogen ions. Nevertheless, the equation is equally true in either sense, as in any given basic solvent the active mass of the latter is nearly constant, and consequently the ratio:

$$\frac{[\text{solvated hydrions}]}{[\text{free hydrions}]}$$

is constant for univalent ions at any fixed temperature. In such cases as the above relations hold, it is also true that:

$$\frac{\text{availability of acid}}{[\text{solvated hydrions}]}$$

is a constant; hence the electromotive force of the concentration cell is also given by:

$$E = \frac{RT}{F} \log_e \frac{P}{P'},$$

where P and P' are the availabilities of the acid in the two liquids (Trans., 1908, 93, 2203, and 1910, 97, 21).

As all the foregoing relations have a sound thermodynamic basis, the question whether "free" hydrogen ions actually exist in such solutions is immaterial at least when passing from the first expression for E to the second, the sole assumptions made being that the gas laws are applicable to the ions, and that the current production is conceived as taking place in a truly reversible manner. The supposition that the elementary hydrogen at the electrodes passes into solution as "free" hydrogen ions is not a necessary part of the

proof, as the same result is obtained if it be supposed that the process occurring at the electrodes is the direct formation of the solvated ions, as, for example:

when the free energy relations of these ions are similar to those usually associated with the "free" hydrogen ions. The ionic solution pressure must then be considered as due to the same reaction.

The formula which shows the connexion between the potential and the availabilities of the acid in the cell compartments is of more general applicability than the one first given, as it is not restricted to cases in which the solvent itself forms complex hydrions. As the only solvents hitherto investigated from this point of view come under the latter category, a general thermodynamic proof of the availability formula, although comparatively simple, is at present hardly necessary.

Occasion may be taken to point out that numerous experiments on alcoholic solutions of mineral acids show that the law of mass action holds as nearly true for such solutions as for aqueous ones. Consequently, the restrictions under which the foregoing formulae are applied are not here appreciably more serious with the one solvent than with the other.

It has already been shown that the anticatalytic effect of water on solutions of mineral acids in organic solvents can readily be accounted for on the view that water behaves as a weak base, so that when it is added to such solutions the concentration of the "free" hydrogen ions is diminished, or the availability of the acid is depressed, and experimental proof of a direct connexion between the catalytic activity and the salt-forming power of hydrogen chloride in alcohol was adduced. In experiments described in the present paper the theory has been put to a further test by ascertaining the electromotive forces obtained with concentration cells containing alcoholic hydrogen chloride as cell liquid, and having electrodes reversible to hydrogen ions.

Preliminary experiments were made with solutions of hydrogen chloride without any subsidiary electrolyte to minimise the potential differences at the liquid boundary, and it was found that with suitable precautions consistent electromotive forces were registered which could be reproduced within less than a millivolt.

The results with solutions having different concentrations of acid in the two compartments were in fairly good agreement with the high value for the transport number of chloridion deduced by other means (Lapworth and Partington, this vol., p. 1420), when neither solution had a concentration of hydrogen chloride much less than $N/10$. With solutions of concentrations considerably less than

N/10, consistent and reproducible electromotive forces were again obtained, but these were almost invariably smaller than those anticipated, by several millivolts, and although various explanations suggest themselves, these cannot at present be tested; additional experiments will be undertaken in the hope of explaining this discrepancy.

Having convinced themselves that sharp and consistent results could be obtained with anhydrous alcoholic solutions, the authors then proceeded to examine what was the effect of the addition of small quantities of pure water to either solution, and observed that when the addition was made to the stronger solution a fall in the electromotive force occurred, whilst if it was made to the weaker solution an increase in the electromotive force occurred.

Quantitative experiments were then carried out, in most cases with solutions of equal concentrations of hydrogen chloride in both cells and with varying quantities of water in one cell only. The influence of small quantities of water was more marked the lower the concentration of acid, an effect which at least in part may be explained by the fact that the active mass of the free water is naturally less in the stronger solutions, as a more considerable part of that which has been added is removed by combination with the hydrogen chloride. With the highly dilute solutions observations were made only with great difficulty, as was to be expected, but with frequent repetition fairly satisfactory records were made.

In these cases any exact interpretation of the results is somewhat difficult, if not impossible, owing to uncertainties in estimating the potential of the liquid boundary. It may be regarded as safe to assume that this is in most cases of relatively small magnitude. The results of Baly, Burke, and Marsden (*Trans.*, 1909, **95**, 1100) show that such small quantities of water affect the degree of dissociation of alcoholic hydrogen chloride to but a relatively small extent, and the same statement applies to the molecular conductivity of such solutions, so that the boundary potential resulting from the inter-diffusion of the ions in the two liquids can have only a secondary importance.

The most satisfactory results of all, however, were obtained with highly dilute solutions of hydrogen chloride in presence of lithium chloride as a subsidiary electrolyte. It was found that if the two cells were filled with an alcoholic solution of this salt, and small quantities of water were added to one of the cells, no definite potential difference could be detected when the apparatus was working in the usual manner. In presence of very dilute hydrogen chloride, however, very considerable electromotive forces were registered, which were easily measured, constant and reproducible.

With the more highly dilute solutions of acid the fall in availability due to the addition of water was in close accordance with the formula:

$$\frac{P'}{P} = \frac{r}{r+w}$$

where P' is the availability of the acid in the moist solution, P that of the acid in anhydrous alcohol, w being the concentration of the water in gram-molecules per litre, and r a constant (compare Trans., 1910, 97, 22). On calculating r by means of this formula for the separate observations, it was found to decrease rapidly with the amount of water present in the stronger solutions, less rapidly with the weaker ones, and always approaching a value 0.122, which was reached with $N/500$ -hydrogen chloride in presence of lithium chloride.

It has been shown in previous papers already referred to, that the availability of this acid as measured by its activity in accelerating the esterification of an acid, or by its power of forming salts with a weak base, may be represented by a formula identical with the above, the value of r approximating to 0.1 at 25° (compare, in particular, Trans., 1910, 97, 22 *et seq.*). Goldschmidt and Udhy, on the other hand, obtained results from measurements of the velocity of the esterification of numerous acids, indicating that the speed is proportional to $1/r+w$ if the value 0.15 be assigned to r (*Zeitsch. physikal. Chem.*, 1907, 60, 735 *et seq.*), so that the discrepancies between results obtained by entirely different methods are not greater than those between values deduced by different observers when using the same method. The relatively small magnitude of the divergence will be clear when it is realised that the presence of less than one-tenth per cent. of water in the alcohol would be sufficient to cause a variation of the same magnitude as is seen in the extreme values hitherto assigned to r at 25°, although it is highly improbable that this is the origin of the discrepancies, which may perhaps be traced when more refined methods have been developed.

The results so far obtained appear to offer unequivocal support for the solvate theory for highly ionised acids, and the expression:

put forward for the first time by Goldschmidt and Udhy as the basis of an explanation of the depressant effect of water on the catalytic activity of acids in promoting esterification, may, if interpreted broadly, be regarded as representing the equilibrium in a highly dilute solution of an acid in moist alcohol. Applied with this reservation and solely to those cases of catalysis and salt formation known to be due exclusively, or nearly so, to reactions

of complex hydrions, the solvate theory renders unnecessary, at least for the present, theories such as that of Reid (*Amer. Chem. J.*, 1909, 41, 499 *et seq.*), where changes in the viscosity of the medium are suggested as one of the principal causes of the anticatalytic influence of water on organic media.

The results of Tubant and his colleagues, obtained by measurements of the speed of inversion of menthone by acids in alcoholic solution (*Annalen*, 1910, 377, 284 *et seq.*), suggest that this reaction is not so nearly exclusively ionic in character as is ordinary accelerated esterification, for the velocities of reaction are not even roughly proportional to the "hydrogen ion" concentration in absolute alcohol as measured by the degree of ionisation of the catalyst. It is therefore not surprising that the influence of water on the reaction appears anomalous when contrasted with the cases dealt with in the present paper.

EXPERIMENTAL.

The apparatus employed for measuring the electromotive forces was that used during the experiments described in Part I. (this vol., p. 1420). The anhydrous alcohol and solutions of hydrogen chloride were prepared as on the former occasion.

The cells used were a pair, each of which was a simple modification of a type in common use, but were joined by means of a narrow glass U-tube. Each cell was provided with a raised reservoir of the solution and with suitable taps, by means of which the levels of the liquids in the cells could readily be adjusted or contact between the cell liquids secured.*

Readings were made by first opening three of the four taps separating the two cells; usually there was enough leakage through the fourth to allow of an approximate estimate of the potential, which could therefore be nearly balanced before this stopcock was opened to obtain a more exact reading. Even after many measurements had been made, involving opening all four taps, the potential varied but imperceptibly, and in no case where numbers are given without comment was there any evidence that a variation in potential had been caused by mixing of the solutions.

Before each experiment the cells and U-tube were carefully cleaned, washed with pure anhydrous alcohol, and dried at 100°.

* The more convenient method usually employed in working with the hydrogen electrode is to use one cell in combination with a calomel electrode; thus, Denham (*Trans.*, 1908, 93, 41) was able to obtain very satisfactory results with aqueous solutions of salts of weak bases, employing such a combination. In the case of alcoholic solutions of hydrogen chloride, however, the calomel electrode has not given such sharp results as the hydrogen electrode, so that it was thought desirable to avoid its use in the present series of measurements.

All measurements were made at $25^{\circ} \pm 0.05$.

In preliminary experiments very unsatisfactory results were obtained, both with electrodes of platinum foil and with others made of platinum films deposited on glass; this was finally found to be due almost wholly to the condition of the platinum surfaces. Constant electromotive forces and consistent results were obtained with platinum plates only when these had been heated to redness, platinised in the usual manner, and washed repeatedly, first with water and then with absolute alcohol, and transferred at once, while still moist, to the cells. At the moment before the insertion of the electrodes the whole of the remainder of the apparatus should otherwise be in full working order, and a fairly rapid stream of hydrogen should have been passing for a sufficiently long time to insure the complete expulsion of all other gases from the vessels, tubes, and solutions. The electrodes should not be used twice, but require cleaning with boiling nitric acid, replatinising, and treating as above before each new experiment.

Electrodes of platinised glass, if newly prepared, coated with platinum black, washed as above and used at once, also gave excellent results, identical with those obtained with the foil-electrodes, but as it was necessary after each experiment to renew the main films and they offered no advantages as compared with the other type of electrodes, their use was discontinued.

When the apparatus was working in a satisfactory manner it was observed that a nearly steady electromotive force was obtained in one or two minutes after the electrodes had been inserted, and when this was not the case, experience showed that it was useless to continue the experiment; if the cells were short-circuited with open taps for several seconds and the circuit then broken, the original potential was attained once more in less than a minute.

Results.

Measurements made during some typical experiments at 25° are given below. In each of the cases which follow immediately, the solutions used in the two cells were prepared from the same specimen of alcohol.

The time is given in hours after the observations were began, usually within two minutes of the insertion of the electrodes. The potentials given are the means of several readings in each case.

The arrows indicate the direction of the positive current inside the cells.

The observations in the two experiments which follow immediately are given to show the influence of time on the potentials observed.

They were chosen at random from a large number of similar records.

(1) *With Slightly Moist Alcohol as Solvent (Commercial Absolute)*
 $H_2, 1.114N-HCl | 0.1021N-HCl, H_2$

Time.	Potential.	Time.	Potential.
0.0 hour	0.0447 volt	1.75 hours	0.0467 volt
0.5 "	0.0447 "	2.5 "	0.0467 "
1.0 "	0.0467 "	3.25 "	0.0467 "

* Although the accuracy of the potentials is not guaranteed within more than a millivolt, individual readings could be compared within 0.2–0.3 millivolt. For the sake of comparisons the calculated means are given in all cases to 0.1 millivolt.

[With cells reversible to chloridion and prepared with the same two solutions, the potential obtained was 0.060 volt at the same temperature.]

(2) *With Alcohol dried over Calcium.*
 $H_2, 0.6341N-HCl | 0.06408N-HCl, H_2$

Time.	Potential.	Time.	Potential.
0.0 hour	0.0281 volt	1.5 hours	0.0281 volt
0.06 "	0.0283 "	4.0 "	0.0283 "
0.91 "	0.0283 "		

The slight rise indicated in the last reading was perhaps due to a slight mixing of the solutions during the considerable time occupied by the experiment.

A number of comparative experiments were made in the early part of the investigation with different electrodes. In all cases where the alcohol was moist a sensibly constant potential was reached within fifteen minutes; thus with solutions of hydrogen chloride in two different concentrations in the cells with 99.7 per cent. alcohol as solvent, tests with seven different electrodes gave potentials between 0.0424 and 0.0490 volt. On the other hand, with solutions prepared from calcium-dried alcohol, constant values of the potentials were obtained almost as soon as it was possible to begin making measurements; thus with 0.6341*N*-hydrogen chloride and 0.06408*N*-hydrogen chloride respectively in absolute alcohol, five different pairs of electrodes of platinised foil gave potentials identical with one another within the limits of the bridge-readings, namely, 0.0282 ± 0.0003 volt. This value is in close agreement with that required, namely, 0.02806 volt if the transport number $(1-n)$ of the chloridion in the solutions is taken as 0.32, which is nearly that deduced by other methods (compare this vol., p. 1420).

Other experiments were made with solutions of hydrogen chloride with concentrations considerably lower than the above; thus the arrangement:

gave a potential of 0·0214 volt, or some seven millivolts less than that obtained for the stronger solutions having much the same total concentration ratio. Other measurements with several different samples of alcohol have shown that when either cell contains a solution having a concentration of hydrogen chloride less than about $N/20$, the potential differences, although steady and reproducible with considerable accuracy, are invariably smaller than those calculated with the above formula by several millivolts. The explanation which first suggests itself, namely, that the value used for the transport number of chloridion in alcohol is too low, or variable, must, in the authors' opinion, be rejected; further, the presence of a constant small quantity of water or other impurity more basic than alcohol would have an influence in the opposite sense from that observed. Pending further investigation, this record of the general nature of these results is the only contribution which need be made at the present time.

The unexpected sharpness of the potentials and the accuracy with which they are reproduced led the authors to proceed at once to the main object they had in view, namely, to investigate the effect of water on the potential of the hydrogen electrode in alcohol, with the results recorded in the following section.

The Influence of Small Quantities of Water on the Potential of the Hydrogen Electrode in Alcoholic Hydrogen Chloride.

The experiments on this aspect of the subject were carried out in much the same manner as those above described. In most cases the contents of one of the cells were quite dry, whilst those of the other contained a known concentration of water.

In the experiments *c*, *d*, *e*, *f*, the total concentration of the hydrogen chloride in the two cells was the same, but varying quantities of water were present in one cell liquid only. The direction of the positive current in the cells was always from the moist solution to the anhydrous one.

In one column are given the values of P''/P calculated by means of the formula (5):

$$E = \frac{RT}{F} \log \frac{P}{P''}$$

These represent the apparent relative values of the concentrations of the free hydrogen ions, or the apparent relative values of the

availability of the acid, in the moist as compared with the anhydrous solution. Cases *b* and *c* approach most nearly the ideal state of low concentration, *c* representing the most dilute solution of hydrogen chloride with which sharp readings could be taken. *a* is the case where still more dilute acid was used with a subsidiary electrolyte.

The values of *r*, the apparent "water-value" of alcohol at 25°, were calculated by means of the formula (Trans., 1910, 97, 22).

$$P' = Pr/r + w,$$

where *P'* is the availability of the acid in the moist solution, *P* that of the acid in the anhydrous solution, and *w* represents the number of gram-molecules of water present in one litre of the moist solution.

The numbers given under (*b*) represent the means of three sets of results, concordant within two millivolts, obtained with three samples of *N*/500-hydrogen chloride in alcohol in presence of an equal concentration of purified lithium chloride (*N*/10) in both cells. Readings were sharp, and were easily made.

(*b*) 0.002*N*-HCl and 0.100*N*-LiCl in both cells; varying quantities of water in the second cell.

Potential.	<i>w</i> .	<i>P</i> / <i>P</i> .	<i>r</i> .
0.0384 volt	0.444	0.224	0.128
0.0467 "	0.666	0.183	0.129
0.0590 "	1.00	0.108	0.122

In case (*c*) readings were also fairly sharp, but in absence of a subsidiary electrolyte measurements were very difficult with solutions less concentrated than *N*/100.

(*c*) 0.01*N* HCl in both cells; water in one cell only.

In the diagram the results of the latter part of the investigation are expressed graphically, and the apparent values of P'/P , or the

relative concentrations of the free hydrogen ions, are indicated in curves *b*–*f* corresponding with the experiments indicated with the letters.

The curve (*a*) is that deduced from measurements of the effect of water on the catalytic activity of very dilute hydrogen chloride

in alcohol, adopting 0.1 as the most probable value of r . The curve representing the results of Goldschmidt and Udby on esterification lies just above c , and its separate insertion on the diagram was hardly possible. Similarly, the results obtained from measurements of the salt-forming power of extremely dilute hydrogen chloride in alcohol is nearly coincident with a and slightly below c . Generally speaking, the more dilute the acid with which the experiments are made the lower the position of the curve on the diagram.

Attention may be drawn to the fact that any tendency for lithium chloride to withdraw part of the water from alcoholic solutions would have the result of raising b towards or above c , but a further result would be a decrease in the apparent value of r with increase in the concentration of water, and there is little evidence of this in the experiments made so far. The value of r in presence of lithium chloride requires determination by other methods, and experiments on the point will be undertaken.

Conclusions.

The solvate theory of acids indicates that, in highly dilute aqueous alcoholic solution the concentration of the free hydrogen ions from a mineral acid may be represented by the expression:

$$[H] = [H_0] \frac{r}{r+w},$$

where $[H_0]$ is the concentration of "free" hydrogen ions in the anhydrous solution, w is the concentration of water in gram-molecules per litre, and r is the "water-value" of the alcohol at the temperature referred to.

If the conception of "free" hydrogen ions is discarded in the absence of any direct proof of their existence, the law may be expressed in terms of the availability, P , of the acid, thus:

$$P = P_0 \frac{r}{r+w},$$

where P_0 is the availability of the acid in anhydrous solution.

Experiments on three entirely independent lines confirm the general applicability of the above formula, and the only discrepancy concerns the precise value of r at 25°; this discrepancy is probably due, however, to the small magnitude of r , and the consequent difficulties in fully eliminating all sources of experimental error, especially as with low concentrations of acid the solutions are very sensitive to certain impurities.

The following estimates of the value of r at 25° have now been made:

- A. *By Measurements of Esterification Velocities* (Catalysis).
 (i) $r=0.15$ (Goldschmidt and Udby).
 (ii) $r=0.10-0.11$ (Lapworth and Partington).
 (iii) $r=0.09-0.095$ (Jones and Lapworth).
 B. *By Measurements of Salt-forming Power* (Availability).
 (iv) $r=0.089-0.108$ (Lapworth and Partington).
 (v) $r=0.095$ (Jones and Lapworth).
 C. *By the E.M.F. of the Hydrogen Electrode* (Concentration of free H^+ ions).
 (vi) $r=0.127$ (Hardman and Lapworth).

Having regard to the numerous sources of error, the numbers given in this communication are only quoted as being approximately correct, and many of the more important ones will be redetermined, with such additional precautions as may suggest themselves; the inquiry into electromotive forces and equilibria in alcohol and other organic media will be extended along lines similar to those suggested in this and previous papers.

Part of the expense of this investigation was defrayed by a grant from the Government Grant Research Fund of the Royal Society, for which the authors desire to express their indebtedness.

 UNIVERSITY OF MANCHESTER.

CCL.—*Polymorphic Phthalylhydrazides.*

By FREDERICK DANIEL CHATTAWAY and DONALD FREDERICK SANDYS WÜNSCH.

Some years ago it was observed that hot saturated solutions of phthalylphenylhydrazide almost invariably deposited crystals of two distinct forms, one orange and the other of so pale a yellow as to seem almost colourless when viewed beside the orange modification; these crystals could easily be separated by hand, and each modification could be obtained in a pure state free from the other following crystallisation to take place at a suitable temperature. Dunlap (*J. Amer. Chem. Soc.*, 1905, 27, 1091) published an account of similar observations while the work was in progress, and was consequently discontinued.

The authors have recently resumed the subject to ascertain if this property of crystallising in two differently coloured forms is common to all the phthalylhydrazides.

So far, only one other instance has been found among the simple phthalyl derivatives, but it seems certain that this is due to the exact conditions necessary for the first appearance of the highly coloured modification not having been realised in the remaining cases. Many observations on related compounds, which will be communicated later, lead to the conclusion that it should be possible to obtain every phthalyl- and substituted phthalylhydrazide in two modifications differing widely in colour and a crystalline form.

The phthalylhydrazides are very easily obtained by heating together at about 100° equivalent amounts of phthalic anhydride and the corresponding hydrazine, when water is eliminated, thus

The phthalylhydrazides crystallise extremely well from ordinary solvents. The modifications separating at the higher temperatures are orange, whilst those separating at the lower temperatures are much paler, in fact, almost colourless. In every case where only one modification has been obtained it is the one having the deep orange colour.

Instances like the foregoing, in which organic substances of the same composition exist in forms showing distinctly different properties, are very frequent.

Such diversities in the case of liquids or gases can always be referred to differences in either the size or structure of individual molecules, and can therefore be formulated according to conventional usage by different structural formulæ. But among substances of the same composition the dissimilar properties may be due either to a difference in the size or the atomic arrangement of the individual molecules, that is, to polymerism or isomerism, or to a difference in the manner in which the molecules group themselves when the substance assumes the crystalline condition—that is, to polymorphism. Although differences of atomic arrangement are generally associated with marked differences in chemical behaviour whilst differences in molecular grouping only cause variations in the physical properties, it is not always easy to decide whether a given pair of substances are isomeric or polymorphic. They are usually regarded as isomeric if any differences of behaviour observed in the solid state persist when the compounds are dissolved, melted, or gasified, or if the two forms in specified reactions carried out under similar conditions yield different derivatives.

The two modifications of the phthalylhydrazides differ only in colour and crystalline shape, and the dissimilarity, so far as is known at present, disappears when the distinct solid substances are

dissolved. They must therefore provisionally be regarded as polymorphic, and not as isomeric or polymeric modifications. Since, however, the phthalylhydrazides may have the unsymmetrical configuration, the possibility that they may be stereoisomerides ought not to be lost sight of.

No differences in the chemical behaviour of the two forms have been observed; it should be noted, however, that their peculiar nature makes it impracticable to obtain derivatives which might decide the point beyond question.

The polymorphic phthalylhydrazides are enantiotropic, the two forms transforming at a definite temperature much below the melting point of either. The change in the solid state, however, takes place so slowly that it is possible for either form to exist in a more or less unstable condition at a temperature below or somewhat above the transition temperature for a limited period, depending on the rate of transformation. The transition points of the two pairs of polymorphic phthalylhydrazides described in this paper are at the present time being determined, and appear not to be very far removed from the ordinary temperature.

On heating a crystal of the colourless modification of phthalylphenylhydrazide to a temperature approaching 100° , the rate of transformation is so much increased that specks of the yellow modification almost at once appear, and grow into the mass until the whole is transformed. This conversion into the orange-coloured form takes place more easily when the white crystals are heated in a saturated alcoholic or acetic acid solution to about 60° or 70° .

Transformation of the orange-coloured phthalylphenylhydrazide into the colourless modification is so slow at the ordinary temperature that, not only may the yellow and colourless crystals be kept in contact for years without apparent change, but both forms can exist side by side for days in a saturated alcoholic solution without the orange-coloured crystals appreciably diminishing or the white crystals increasing in size.

Crystals of the pale yellow modification of phthalylphenylmethylhydrazide similarly transform quickly into the orange when heated to the neighbourhood of 100° , while the orange-coloured crystals when dry remain unchanged for months at the ordinary temperature. On the other hand, if crystals of the orange-coloured modification of phthalylphenylmethylhydrazide are placed in a saturated alcoholic solution at the ordinary temperature in presence of a crystal of the pale modification, they become completely transformed in a few hours, the orange-coloured crystals dissolving, and cell-shaped crystals of the very pale yellow form taking their place.

Either form of phthalylphenylhydrazide or of phthalylphenyl-

methylhydrazide can be obtained at will by slightly supersaturating a solution above or below the transition temperature and placing in it a crystal of the required modification. As, however, the difference in solubility of the two forms is at any temperature slight compared with the change of solubility as the temperature varies, a hot solution on cooling may pass into the metastable or even into the labile condition for the pale form, even when crystals of the orange form are present, so that, as might be expected, crystals of both modifications frequently separate together.

For convenience of reference the crystallographic constants of the substances described in this paper are given in the following table¹:

Hydrazide.	Modification.	System.	Crystallographic constants.
Phthalylphenyl	Bright yellow	Monoclinic	$a : b : c = 1.1573 : 1 : 1.154$ $\beta = 126^{\circ}26'$
Phthalylphenyl	Pale yellow	Orthorhombic	$a : b : c = 1.0875 : 1 : 0.75$
Phthalyl- <i>p</i> -tolyl	Deep orange	Monoclinic	$a : b : c = 1.7525 : 1 : 0.75$ $\beta = 126^{\circ}30'$
Phthalyl- <i>o</i> -tolyl	Bright orange	Monoclinic	$a : b : c = 0.5555 : 1 : 0.75$ $\beta = 96^{\circ}5'$
Phthalyl- <i>p</i> -bromophenyl	Bright yellow	Monoclinic	$a : b : c = 1.5047 : 1 :$ $\beta = 103^{\circ}7'$
Phthalyl- <i>p</i> -chlorophenyl	Bright yellow	?	?
Phthalylphenyl-methyl	Bright orange	Triclinic	$a : b : c = 0.5853 : 1 : 0.75$ $\alpha = 110^{\circ}0'$, $\beta = 114^{\circ}0'$ $\gamma = 68^{\circ}17'$
Phthalylphenyl-methyl	Pale yellow	Monoclinic	$a : b : c = 0.7569 : 1 : 0.75$ $\beta = 92^{\circ}10'$
Phthalylphenyl-benzyl	Bright orange	Monoclinic	$a : b : c = 0.8773 : 1 : 0.75$ $\beta = 93^{\circ}49'$
Phthalyl- α -naphthyl	Orange	?	?
Phthalyl- β -naphthyl	Orange	?	?

Phthalylphenylhydrazide has been described by Pickel (*Annalen*, 1886, **232**, 232), Hötte (*J. pr. Chem.*, 1886, [ii], **33**, 99; 1887, **35**, 265), Pellizzari (*Gazzetta*, 1886, **16**, 203), Just (*Ber.*, 1887, **19**, 1204), Henriques (*Ber.*, 1888, **21**, 1616), and Eibner and Meke (*Ber.*, 1902, **35**, 2300). Their descriptions of the compound do not agree, especially as regards its colour, evidently owing to one or other of the modifications only having been observed. It is best obtained by dissolving phthalic anhydride in alcohol, adding the equivalent amount of phenylhydrazine, freshly distilled and free

¹ This and all the other descriptions of the crystals given in this paper have been furnished to us by Mr. T. V. Barker, Demonstrator of Mineralogy in the University of Oxford.

from aniline, evaporating off the alcohol, and heating the yellow, solid mass remaining on a water-bath until water-vapour ceases to be given off.¹

The bright yellow form is best obtained by dissolving as much of the compound as possible in boiling glacial acetic acid or toluene, cooling slightly, and, after adding a few specially chosen crystals of this modification, allowing the temperature to fall very slowly. This operation is most conveniently carried out by placing the carefully corked flask in a hot water-jacketed cooler, so surrounded by cotton waste that several days are required for the temperature to fall to that of the laboratory. Bright yellow, monoclinic crystals of short and compact habit then separate, invariably free from crystals of the pale-coloured modification.

Phthalylphenylhydrazide
(yellow modification).

The ratios of the axes are $a:b:c=1.1573:1:1.2040$; $\beta=126^{\circ}26'$. The following forms were observed: $m-\{110\}$, $c-\{001\}$, $t-\{203\}$, $r-\{101\}$, $q-\{011\}$, $o-\{111\}$, $s-\{211\}$, $p-\{112\}$, and $e-\{012\}$. The habit of the crystals is shown in Fig. 1, the form r being rarely observed. Following is a table of measured and calculated angles:

	No.	Limits.	Mean.	Calc.
$m-m = 110:1\bar{1}0$	7	$87^{\circ}15' - 87^{\circ}33'$	$87^{\circ}20'$	—
$m-c = 110:001$	3	$65^{\circ}52' - 65^{\circ}59'$	$65^{\circ}56'$	$65^{\circ}51'$
$m-q = 110:011$	8	$38^{\circ}51' - 39^{\circ}10'$	$39^{\circ}2'$	—
$c-q = 001:011$	15	$44^{\circ}44' - 44^{\circ}52'$	$44^{\circ}48'$	—
$c-t = 001:012$	2	$26^{\circ}15' - 26^{\circ}20'$	$26^{\circ}17'$	$26^{\circ}24'$
$p-t = 112:203$	3	$32^{\circ}50' - 33^{\circ}10'$	$32^{\circ}59'$	$33^{\circ}1'$
$m-q = 110:011$	12	$78^{\circ}40' - 78^{\circ}52'$	$78^{\circ}45'$	$78^{\circ}41'$
$t-c = 001:203$	2	$43^{\circ}11' - 43^{\circ}34'$	$43^{\circ}22'$	$43^{\circ}16'$
$t-r = 203:101$	2	$20^{\circ}56' - 21^{\circ}2'$	$20^{\circ}59'$	$21^{\circ}6'$
$m-s = 111:211$	4	$29^{\circ}26' - 29^{\circ}42'$	$29^{\circ}34'$	$29^{\circ}22'$

There is a perfect cleavage parallel to $c-\{001\}$, an imperfect one parallel to $m-\{110\}$. The optical extinction on m is straight, and an optic axis emerges obliquely through q . $D_D^{20} 1.356$. Molecular volume = 175.5.

The pale yellow form is best obtained by saturating toluene with the compound at about 50° , boiling for a few moments to remove all traces of crystals from the sides of the flask, and allowing to

¹ If the mass is heated much above 100° or fused, the hydrazide partly or completely decomposes according to the duration of the heating into phthalanil, ammonia, and nitrogen.

FIG. 2.

Phthalylphenylhydrazone (pale modification).

cool to about 25°. As a rule, no crystals separate. A carefully chosen fragment of the pale yellow modification is then added, and the temperature slowly allowed to fall to the cooler to that of the laboratory. The pale yellow form then separates, free from crystals of the more highly coloured form, in very faintly tinted orthorhombic plates, with $a : b : c = 1.0875 : 1 : 0.5568$. The observed forms were: $b - \{010\}$, $m - \{110\}$, $r - \{101\}$, $n - \{212\}$, $l - \{210\}$, $q - \{011\}$, $s - \{012\}$, and $v - \{230\}$. A typical crystal is shown in Fig. 2, and the observed and calculated angles follow:

	No.	Limits.	Mean.	Calc.
$ba = 010 : 230$	2	31° 27'—31° 39'	31° 33'	31° 33'
$bm = 010 : 110$	20	42° 28'—42° 43'	42° 36'	42° 36'
$ml = 110 : 210$	3	18° 42'—18° 49'	18° 46'	18° 46'
$bo = 010 : 212$	1	—	76° 7'	76° 5'
$bq = 010 : 011$	2	60° 51'—60° 53'	60° 52'	60° 52'
$bs = 010 : 012$	5	74° 17'—74° 28'	74° 23'	74° 23'
$vr = 110 : 101$	6	71° 59'—72° 6'	72° 2'	72° 2'
$rq = 101 : 011$	4	38° 53'—39° 7'	39° 3'	38° 57'

There is a fairly good cleavage parallel to $b - \{010\}$. Optically, the crystals clearly show their orthorhombic symmetry, the c mean line being parallel to the axis, a , with axial plane $c - \{001\}$. $2H_N = ca\ 70^\circ$, $\rho > v$. $D_4^{20} = 1.354$. Molecular volume = 175.

The pale yellow modification when placed in a saturated solution in any solvent at about 60° rapidly dissolves and disappears, while deep yellow crystals separate out, so that the pale compound appears to transform into a more highly coloured one. The crystals separating often preserve to some extent the plate-like shape of the pale yellow modification, but when examined with a lens are seen to be paramorphs, consisting of small crystals of the yellow form. Determinations of the solubilities which are proceeding indicate that the transition temperature is not far above the ordinary. Transformation also takes place when the pale crystals are heated alone, but more slowly than in presence of a solvent. If large crystals of the pale form are heated to 100°, deep yellow spots quickly appear, and extend through the crystals until, after some hours' heating, the latter are transformed into opaque paramorphs of the yellow modification. This transformation is much more rapid at a higher temperature, and prevents the melting point of the pale modification being determined; even with rapid heating transformation is complete before the melting point is reached. The deep yellow modification melts at 184°. So far the transforma-

tion of the yellow into the pale modification has only been effected by dissolving the former, and allowing the pale modification to crystallise out at a comparatively low temperature. The rate of transformation at the ordinary temperature is so slow that crystals of the two forms can be left for weeks in a saturated alcoholic solution without any appreciable growth of the pale crystals. In the solid state the yellow form can be left in contact with the pale form for years at the ordinary temperature without any perceptible alteration.

This substance is best prepared by dissolving equivalent amounts of phthalic anhydride and *p*-tolylhydrazine in alcohol, evaporating to dryness, and heating the solid residue on a water-bath until water-vapour is no longer given off. It is moderately readily soluble in boiling alcohol, toluene, or acetic acid, and separates in long, deep orange-yellow, prismatic crystals, which melt at 196°. The colour of this compound is very similar to that of the bright yellow modification of phthalylphenylhydrazide, but of a somewhat deeper shade. No pale modification corresponding with the second form of phthalylphenylhydrazide has yet been obtained. When crystallised from any solvent the orange modification separates, both at high and low temperatures:

0.3692 gave 29.4 c.c. N_2 (moist) at 11° and 758 mm. $\text{N} = 11.25$.

$\text{C}_{17}\text{H}_{15}\text{O}_2\text{N}_2$ requires $\text{N} = 11.11$ per cent.

The crystals proved to be monoclinic with $a : b : c = 1.7525 : 1 : 0.7914$; $\beta = 126^\circ 30'$. The observed forms were: $m = \{110\}$, $q = \{011\}$, $b = \{010\}$, and $r = \{101\}$. The forms m and q predominated equally, whilst b was much smaller and r often failed. The habit is shown in Fig. 3.

FIG. 3.

Phthalyl-*p*-tolylhydrazide.

	No.	Limits.	Mean.	Calc.
$\delta m = 010 : 110$	2	35° 25' - 35° 33'	35° 29'	35° 29'
$\alpha m = 110 : 110$	4	70 36 - 70 52	*70 44	—
$\alpha q = 110 : 011$	7	43 12 - 43 21	*43 16	—
$\alpha r = 110 : 101$	3	62 10 - 63 5	62 33	62 41
$r q = 101 : 011$	3	35 16 - 35 58	35 40	35 47
$q m = 011 : 110$	9	98 19 - 98 37	*98 28	—
$q r = 011 : 011$	2	64 34 - 64 52	64 43	64 55

There was no observable cleavage; optically the crystals are in full agreement with monoclinic symmetry; the extinction on the face *m* makes an angle of 29° with the edge *mm*. $D_x = 1.312$. Molecular volume = 191.2.

Phthalyl-o-tolylhydrazide.

Phthalyl-o-tolylhydrazide was obtained exactly as the parent compound by the interaction at 100° of equivalent quantities of phthalic anhydride and *o*-tolylhydrazine. It is moderately readily soluble in all ordinary organic solvents, and crystallises well from hot alcohol, toluene, or glacial acetic acid in small, tabular monoclinic crystals of a bright orange colour (compare Fig. 4), which melt at 198° . The pale modification has not yet been obtained:

FIG. 4.

Phthalyl-o-tolylhydrazide.

0.2648 gave 24.98 c.c. N_2 (moist) at 14° and 760 mm. $N = 11.4$

$C_{15}H_{12}O_2N_2$ requires $N = 11.11$ per cent.

The calculated ratios of the axes are: $a:b:c = 0.5555:1.0:0.7491$, $\beta = 96^\circ 5'$. The forms observed were: $c - \{001\}$, $m - \{110\}$, $n - \{120\}$, and $q - \{011\}$. The measured and calculated angles follow:

	No.	Limits.	Mean.	Calc.
$qq = 011:0\bar{1}1$	3	$73^\circ 13' - 73^\circ 28'$	$73^\circ 20'$	$73^\circ 22'$
$cq = 001:011$	5	$36^\circ 31' - 36^\circ 45'$	$36^\circ 41'$	—
$mq = 110:011$	2	$77^\circ 31' - 77^\circ 40'$	$77^\circ 35'$	$77^\circ 37'$
$nq = 110:011$	3	$68^\circ 38' - 68^\circ 47'$	$68^\circ 42'$	—
$cm = 001:110$	2	$84^\circ 40' - 84^\circ 45'$	$84^\circ 42'$	$84^\circ 40'$
$nm = 120:110$	4	$18^\circ 47' - 19^\circ 30'$	$19^\circ 1'$	$18^\circ 26'$
$mm = 110:1\bar{1}0$	5	$57^\circ 48' - 57^\circ 56'$	$57^\circ 50'$	—

$D_x^{25} = 1.383$. Molecular volume = 182.3.

Phthalyl-p-bromophenylhydrazide, $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} N \cdot NH \cdot C_6H_4Br$

The interaction of phthalic anhydride and *p*-bromophenylhydrazine at 100° , under conditions similar to those previously described, produces *phthalyl-p-bromophenylhydrazide*. This compound is moderately readily soluble in all ordinary organic solvents, and crystallises from hot alcohol or toluene in bright yellow, monoclinic prisms, very closely resembling in colour the yellow modification of phthalylphenylhydrazide. It melts at 206° . The pale modification has not yet been obtained:

0.2022 gave 0.1226 AgBr. $Br = 25.80$.

$C_{14}H_9O_2N_2Br$ requires $Br = 25.21$ per cent.

FIG. 5.

Phthalyl-p-bromophenylhydrazide.

The crystals are six-sided prisms of the monoclinic system (compare Fig. 5), with the axial ratios having the values $a : b : c = 1.047 : 1 : 1$; $\beta = 103^\circ 7'$. The only forms observed were $a = \{100\}$, $m = \{110\}$, and $c = \{001\}$, and the relative length of the vertical axis, c , could not accordingly be determined. The following angles were measured and calculated:

	No.	Limits.	Mean.	Calc.
α $a : 110 : 100$	5	$55^\circ 34' - 55^\circ 50'$	$55^\circ 41'$	$55^\circ 41'$
β $a : 110 : 110$	6	$68^\circ 35' - 68^\circ 39'$	$68^\circ 37'$	—
γ $c : 001 : 100$	3	$76^\circ 49' - 77^\circ 0'$	$76^\circ 53'$	—

There is no observable cleavage. $D_4^{25} 1.682$. Molecular volume = 182.5.

Phthalyl-}p\text{-chlorophenylhydrazide} was prepared as above described from *p*-chlorophenylhydrazine. It resembles the *p*-bromo-compound very closely. It crystallises from hot alcohol or toluene in bright yellow prisms, which are too slender to admit of measurement. It melts at 191° :

$n_D^{25} 1.851$ gave 0.1001 AgCl. Cl = 13.35.

$C_{14}H_8O_2N_2Cl$ requires Cl = 13.01 per cent.

Phthalylphenylmethylhydrazide affords the best example of the polymorphism yet met with among compounds of this class, as each form can be easily obtained and transformed into the other. It is prepared exactly as the other hydrazides described in this paper by dissolving equivalent quantities of phthalic anhydride and phenylmethylhydrazine in alcohol, evaporating off the solvent, and leaving the solid residue on a water-bath for some hours until water-vapour is no longer given off. The yield is practically theoretical. It is moderately soluble in all ordinary organic solvents, and crystallises well from hot solutions in toluene or alcohol. When such a solution is allowed to cool, the modification stable at the higher temperature crystallises out in long, bright orange-coloured, triclinic prisms. If these crystals are allowed to remain in the mother liquor for some days, stouter crystals of the modification stable at a lower temperature and exhibiting a very pale yellow tinge make their appearance, and grow at the expense of the orange-coloured crystals, which become etched, dissolve away, and finally disappear. At the ordinary temperature of the laboratory a few grams become completely transformed in a day or so, depending on the size of the

original crystals. The pale yellow crystals of the modification stable at the lower temperature being produced thus under ideal conditions, as the solution is always slightly supersaturated with regard to them, are especially fine in shape and appearance. When crystals of the pale form are placed in a saturated alcoholic solution at about 40° , they rapidly pass into solution, and crystals of the orange-coloured modification appear in their place. The exact transition point is being determined. When a crystal of the pale form is heated at 100° , specks of the yellow form soon appear, and grow until an opaque paramorph of the original crystal is produced, consisting of small crystals of the orange modification. This change becomes very rapid a few degrees above 100° , this being much below the melting point of the pale yellow modification, which consequently cannot be determined. The orange-coloured modification melts at 127° :

Orange Modification:—

0.3543 gave 34.2 c.c. N_2 (moist) at 15° and 758 mm. $N=11.22$.

Pale Yellow Modification:—

0.2333 gave 22.5 c.c. N_2 (moist) at 15° and 758 mm. $N=11.21$.

$C_{15}H_{12}O_2N_2$ requires $N=11.11$ per cent.

The essential difference between the two forms is clearly brought out by the following crystallographic determination, for they crystallise in different systems.

(1) *Orange Modification.*

The crystals are triclinic, and have the following crystallographic constants: $a : b : c = 0.5853 : 1 : 0.3801$; $\alpha = 110^{\circ}0'$, $\beta = 114^{\circ}15'$, $\gamma = 68^{\circ}17'$.

Forms: $b - \{010\}$, $a - \{100\}$, $m - \{1\bar{1}0\}$, $c - \{001\}$, $r - \{101\}$, $p - \{10\bar{1}\}$, $q - \{011\}$, and $o - \{1\bar{1}1\}$. Two crops of crystals, from alcohol and toluene respectively, were found not to exhibit quite the same combination of forms; the crystals of the first crop showed all the forms enumerated with the exception of r , while those of the second crop were characterised by a combination of forms b , a , m , p , c , and r , and, moreover, were generally twins, with b as twin and composition plane. Typical crystals are shown in Figs. 6 and 7. The crystals were measured on the two-circle goniometer, and the observed and calculated values for the angles ϕ and ρ are given in the following table:

FIG. 6.

FIG. 7.

Phthalylphenylmethylhydrazide.
(Single crystal.) Yellow modification
(twin.)

Form.	No.	Mean observed.		Calculated.	
		ϕ .	ρ .	ϕ .	ρ .

$r\{twin\}$	1	92 36	49 0	92 11	49 21

Cleavage: perfect parallel to $b-\{010\}$, imperfect parallel to $m-\{110\}$. D_4^{25} 1.352. Molecular volume = 186.5.

(2) Pale Modification.

A typical crystal is shown in Fig. 8. The crystals are monoclinic with $a:b:c = 0.7659 : 1 : 0.5306$; $\beta = 92^\circ 10'$. Forms: $c-\{001\}$, $m-\{110\}$, $n-\{120\}$, $q-\{011\}$, and $o-\{111\}$; the last form was only observed once. The measured and calculated angles from three crystals are given in the following table:

FIG. 8.

Phthalylphenylmethylhydrazide (pale modification).

Face.	No.	Mean measured.		Calculated.	
		ϕ .	ρ .	ϕ .	ρ .
n-120	11	33°15'	—	33° 9'	—
m-110	11	52°54'	—	—	—
c-001	3	91°21'	2°10'	90° 0'	—
q-011	6	4° 9'	28° 1'	4° 17'	—
o-111	1	54° 9'	42°15'	54° 3'	42°5'

Cleavage: parallel to basal plane {001} perfect. Optics: extinction on m 21°. An optic axis obliquely visible through {001}, and its position points to the optic axial plane being the plane of symmetry. Birefringence strong. D_4^{20} 1.327. Molecular volume = 189.9.

Phthalylphenylbenzylhydrazide was prepared as before described from phthalic anhydride and phenyl benzylhydrazine. It crystallises from alcohol or toluene in bright orange-coloured, monoclinic prisms (compare Fig. 9) which melt at 132°. The pale-coloured modification has not yet been obtained:

Fig. 9.
Phthalylphenylbenzylhydrazide.

0.2656 gave 20.2 c.c. N_2 (moist) at 18° and 756 mm. $N = 8.69$.

$C_{21}H_{16}N_2O_2$ requires $N = 8.54$ per cent

The calculated ratios of the axes are: $a:b:c = 0.8873:1:0.7729$; $\beta = 93^\circ 49'$, the observed forms being: $m - \{110\}$, $r - \{101\}$, $r' - \{101\}$, and $q - \{011\}$. The predominant terminal face was always $r - \{101\}$; the form $q - \{011\}$ was not present on all the crystals, and was very small.

Face.	No.	Limits. ϕ .	Limits. ρ .	Mean.		Calculated.	
				ϕ .	ρ .	ϕ .	ρ .
m-110	9	48°25'—48°34'	—	48°29'	90° 0'	—	—
r-101	3	89°36'—90°17'	43° 6'—43°23'	89° 54'	43° 13'	90° 6'	—
r'-101	3	89°46'—90° 0'	38°46'—38°59'	89° 53'	38° 53'	90° 0'	—
q-011	2	4°31'—4°43'	37°43'—38° 1'	4° 27'	37° 52'	4°52'	37°43'

There was no observable cleavage; the optical extinction on the prism is 4° with the prism edge, on $r - \{101\}$ diagonal. D_4^{20} 1.445. Molecular volume = 264.5. The double refraction is strong.

Phthalyl- α -naphthylhydrazide, $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} N \cdot NH \cdot C_{10}H_7$.

Phthalyl- α -naphthylhydrazide, which was prepared in the ordinary manner from α -naphthylhydrazine, crystallises from alcohol in slender, orange-coloured, flattened prisms, which melt at 221° :

0.3944 gave 31.7 c.c. N_2 (moist) at 10° and 760 mm. $N = 9.58$.

$C_{18}H_{12}O_2N_2$ requires $N = 9.7$ per cent.

Phthalyl- β -naphthylhydrazide,

Phthalyl- β -naphthylhydrazide, prepared as before from β -naphthylhydrazine, crystallises from alcohol in slender, orange-coloured, flattened prisms, which melt at 184° :

0.2673 gave 21.7 c.c. N_2 (moist) at 10° and 760 mm. $N = 9.67$.

$C_{18}H_{12}O_2N_2$ requires $N = 9.7$ per cent.

Both phthalyl- α -naphthylhydrazide and phthalyl- β -naphthylhydrazide crystallise well from hot alcohol or toluene, in which they are sparingly soluble, but neither compound gave crystals adapted for measurement. Only the orange-coloured modification of each was obtained.

The authors desire to thank Mr. T. V. Barker for his kindness in measuring and examining all the crystals described, and for much help during the progress of the work, and also the Government Grant Committee of the Royal Society for a grant which has partly covered the cost of the material used.

UNIVERSITY CHEMICAL LABORATORY,
OXFORD.

COLL.—*The Influence of Inactive Electrolytes on the Optical Activity of l-Malic Acid in Aqueous Solution.*

By CLIFFORD MORGAN STUBBS (1851 Exhibition Scholar of the University of New Zealand).

ALTHOUGH the influence of solvents on the rotatory power of optically active solutes has been much studied in recent years, much more work remains to be done before its nature will be made generally clear. A field not yet very widely explored is the case of the addition of electrolytes to aqueous solutions of active

substances. A study of the effect of this change of solvent on the rotation might be fruitful in helping to a solution of the general problem. Apart from cases where chemical reaction between solute and added electrolyte takes place (for example, in the formation of well known active hydroxy-acid complexes), the influence of inorganic salts has been investigated in the case of certain active sugars by several workers, for example, Farnsteiner (*Ber.*, 1899, **23**, 3570), Rimbach (*Zeitsch. physikal. Chem.*, 1892, **9**, 707), Rimbach and Weher (*ibid.*, 1905, **51**, 473), and Wender (*Biochem. Zeitsch.*, 1911, **30**, 357). The effects generally are small, increase with increasing salt addition, and in some cases show regularities according to the periodic system. In the present research it was attempted to make a systematic and exhaustive study of the influence of electrolytes on the rotation of *l*-malic acid. The great sensitiveness of the latter to various solution changes, for example its formation of abnormally active complexes with salts of certain multivalent elements, and the actual change from *l*- to *d*-rotation during concentration of its aqueous solution (Schneider, *Annalen*, 1881, **207**, 257), together with the large number of data which this sensitiveness has called forth, make malic acid eminently suitable for the investigation.

There is one very obvious objection to its use, however, which must here be met, namely, the fact that it is itself an electrolyte, although a weak one, and that adjustment of ionic equilibrium will therefore complicate the observed effects. That this complicating influence is, however, very small is shown by the following calculation. In a typical case, to be described later, 0.25 of an equivalent of potassium chloride was added to 500 grams of a 20 per cent solution of malic acid. The system would come to equilibrium according to the equation:

($\bar{\text{A}}$ represents the group $\text{H}_2\text{C}_4\text{O}_5$. The middle row gives the degree of dissociation, and the bottom row the gram-molecules present per V litres, of the various substances, when equilibrium is reached.) Then by a calculation due to Arrhenius and van Laar (compare also *Zeitsch. physikal. Chem.*, 1896, **19**, 485) the following equations are obtained:

$$a_1\{(1-x)a_1 + (n-x)a_2 + xa_3 + xa_4\} = kV(1-a_1) \quad \text{. . . (i)}$$

(k being the dissociation constant of $\text{H}\bar{\text{A}}$),

$$\text{and} \quad (1-x)(n-x)a_1a_2 = x^2a_3a_4 \quad \text{. (ii)}$$

$$\text{also, to a first approximation, } x^2 = \frac{kV}{a_3a_4} \quad \text{. (iii)}$$

In the case under consideration, α_2 , α_3 , α_4 may be taken approximately equal, say, each to 0.78, the degree of dissociation of potassium chloride at the dilution used. It may be calculated that $\alpha_1 = 0.637$, and $n = 0.335$; also $k = 3.95 \times 10^{-4}$ (Ostwald, *Zeitsch. physikal. Chem.*, 1889, 3, 369); hence from (iii), to a first approximation, $x = 0.0203$.

Therefore from (i), $\alpha_1 = 0.00092$, and therefore from (ii) to a second approximation, $x = 0.01912$. Hence the percentage of potassium as hydrogen malate = $\frac{0.01912 \times 100}{0.335} = 5.706$; or percentage as undissociated hydrogen malate = $5.706 \times 0.22 = 1.255$. The extent of ionic reaction is therefore in this and similar cases very small; and in actual practice any possible effect on the rotation due to it was completely overshadowed by large influences of another sort.

EXPERIMENTAL.

Apparatus and Method.—The rotation of the solutions was read by a Schmidt and Haensch three-field polarimeter; ten to fifteen readings being taken for each solution, in most cases an accuracy to within a few thousandths of a degree being attained. The temperature was in all cases 20° , the thermometer being standardised, and reading to tenths. Yellow sodium light was used, obtained from a flame illuminated by sodium chloride, and filtered through 2.5 cm. of a 6 per cent. solution of potassium dichromate, this giving Landolt, "Das opt. Drehungsvermögen," p. 364) a mean wavelength of 589μ . Density was determined by means of a pycnometer of about 15 c.c. content.

Kahlbaum's malic acid was used. Of the salts, most were the "pure, for analysis" salts used in the laboratory; a few had to be specially prepared; some (for example, zinc chloride) were obtained in solution, the strength of the latter being determined by analysis. For comparative purposes it was considered best to add the various salts in equivalent quantities to malic acid solutions of the same strength, namely, 100 grams of malic acid: 400 grams of water, in most cases. Such a solution is about 1.5 molecular, and, without being too concentrated, made possible sufficiently large and accurate results. Where the anhydrous electrolytes could not conveniently be used, hydrates or solutions of them were added to more concentrated malic acid solutions in such proportions that the ratio, malic acid: total water: equivalents of electrolyte, was as given. To make up the 20 per cent. solution above described, malic acid, dried over sulphuric acid until no further loss of weight occurred, was added to four times its weight of water. The composition determined by titration against barium hydroxide standardised by

baum's malic acid. A repetition of the measurements in the cases (a) and (c), where the rotation varies most from the mean, confirmed the values given. The constancy of the density in the five cases shows that there was no appreciable difference in the percentage composition of the solutions; hence it must be concluded that the figures in the last column indicate actual differences in the rotatory power of the malic acid used. The explanation is no doubt to be found in the difficulty of obtaining chemically pure a substance so liable to the influence of traces of impurities, to polymerisation, anhydride-formation, and possibly racemisation.

In the following tables n = number of equivalents of salt added to 500 grams of a 20 per cent. solution of malic acid. Under the

Effect of Alkali Salts on the Rotation.

(a) Oxidation of the potassium iodide took place in the acid solution, which gradually turned brown; but when the readings were taken this action had probably not advanced far enough to affect them materially.

A projected measurement of the effect of potassium fluoride had to be abandoned, as sufficient hydrogen fluoride was liberated in the acid solution to have attacked and spoiled the glass polarimeter tube.

(b) Insufficient solubility prevented the use of a higher concentration of potassium sulphate.

2270 STUBBS: INFLUENCE OF INACTIVE ELECTROLYTES ON THE

column headed " $[\alpha]_D^{20}$ for pure acid" is given the specific rotation of the particular 20 per cent. solution of malic acid to which the salt was added. Δ denotes the change in a dextro-direction of the

FIG. 1.

rotation caused by the addition of the salt, and is thus a measure of its influence on the rotation.

It is seen from the above table that in all cases the addition of the salts has markedly influenced the rotation, turning it in a

dextro-direction, and in most cases actually changing a levo- into a dextro-rotation. If the typical case of potassium chloride is considered, it is seen how this influence, measured by Δ , varies continuously with the amount of salt added, Δ increasing as the amount of salt increases, but not quite proportionally. Fig. 1 shows graphically the influence of most of the alkali salts, Δ being plotted as ordinate, and the content in salt, n , as abscissa. There is thus obtained, for example, for potassium chloride, a very regular curve, passing through the origin and the four points determined, and with slight curvature convex upwards. For the other salts the data give only two points on each curve, besides the origin; but their position leaves no doubt that they lie on curves similar in point of regularity and of general appearance to that of potassium chloride. It was thought unnecessary to determine more points on these curves, those given illustrating with sufficient accuracy the nature of the result obtained.

The relative influences of the various salts are somewhat different at different concentrations; this is shown clearly in Fig. 1 by the varying curvature, and even crossing, of the curves. In investigating the connexion between the chemical nature of the salts and their comparative effects on the rotation, a definite equivalent concentration at which to compare these must therefore be chosen. An infinitely small concentration commends itself for this, for disturbing factors such as varying degree of dissociation of the salt, internal pressure, etc., will then be least evident; whilst at higher concentrations they may produce the divergencies from proportionality shown in the curves. Practical measurements of Δ being, however, impossible with a very small concentration of salt, an approximation will be obtained in comparing the values of Δ at the relatively low concentration for which $n = \frac{1}{4}$. Carrying out this comparison, it is evident from the curves that the influence of the salts on the rotation varies regularly with their chemical nature. For positive radicles the effects are in the order:

for negative, $\text{I} > \text{Br} > \text{Cl} > \text{NO}_3 > \frac{1}{2} \text{SO}_4$. A numerical comparison reveals a striking regularity, shown by the following table:

TABLE III.

	Δ .	Diff.		Δ .	Diff.		Δ .	Diff.
KCl	1.95	0.28	NaCl	1.88	0.27	$\frac{1}{2} \text{K}_2\text{SO}_4$...	1.48	0.34
NaCl	1.67	0.51	NaNO_3 ...	1.61	0.50	$\frac{1}{2} \text{Na}_2\text{SO}_4$...	1.14	0.49
NH_4Cl	1.16		NH_4NO_3 ...	1.11		$\frac{1}{2} (\text{NH}_4)_2\text{SO}_4$	0.65	

* For " $n = \frac{1}{4}$ " additions of salt the effects of cesium, rubidium, and potassium chlorides are actually equal, but the shape of the curves (Fig. 2) seems to show that at lower concentrations of salt the order of influence is as given.

From the close agreement between the columns headed " Δ ," it must be concluded that the effect of each of these alkali salts may be regarded as the sum of two terms, distinctive of the positive and negative radicles of the salt. The absolute value of the influence due to each radicle obviously cannot be decided, only the relative, for example, from the above table:

$$K - Na = \text{about } 0.30^\circ.$$

$$Na - NH_4 = \text{about } 0.50^\circ.$$

and consequently, $K - NH_4 = \text{about } 0.80^\circ.$

From a consideration of the above results and those to be described, it seems probable that the main influence is exerted by the positive radicle.

Effect of Barium and Calcium Salts.

TABLE IV.

Salt.	n .	α_D^{20} .	α_D^{25} .	$[\alpha]_D^{25}$.	$[\alpha]_D^{25}$ for pure acid	Δ .
BaCl ₂	$\frac{1}{2}$	1.1256	1.976°	4.82°	-0.96	5.58°
BaCl ₂	1	1.2586	6.769	16.27	-0.96	17.51
(a) Ba(NO ₃) ₂	$\frac{1}{2}$	1.133	1.652	3.88	-0.95	4.43
CaCl ₂	$\frac{1}{2}$	1.1018	1.226	2.86	-1.00	3.96
(b) CaCl ₂	1.019	1.166	5.758	13.72	-1.09	14.41
(b) Ca(NO ₃) ₂	0.2998	1.1155	1.455	3.42	-0.95	4.47
Ca(NO ₃) ₂	1	1.1917	4.552	11.12	-0.95	12.07

(a) Insufficient solubility prevented the use of a higher concentration of barium nitrate.

(b) In these cases a too great quantity of salt was inadvertently added, as is shown under column " n ." In the case of calcium nitrate, where the effect for $n = \frac{1}{2}$ is of interest for comparative purposes, interpolation gives 3.69° as the value of Δ for that concentration of salt.

The order of influence of the radicles of the above table is $Ba > Ca$, and as in the case of the alkali salts, $Cl > NO_3$. For the concentration $n = \frac{1}{2}$ we have:

TABLE V.

	Δ .	Diff.		Δ .	Diff.
BaCl ₂	5.58°	1.63°	Ba(NO ₃) ₂ ...	4.83°	1.14°
CaCl ₂	3.95		Ca(NO ₃) ₂ ...	3.69	

The numbers under " Δ ," do not agree so closely as in the case of the alkali salts, barium nitrate giving a smaller effect than would be expected. It is very significant that, as appears from conductivity tables (Landolt-Börnstein, "Tabellen," p. 745), the dissociation of barium nitrate in aqueous solution at the concentration used is abnormally low; for whilst barium and calcium chlorides show practically equal degrees of dissociation in $N/2$ -solution, that of barium nitrate is only about five-sixths that of calcium nitrate. A

connexion thus appears to exist between the degree of dissociation of a salt and its influence on the rotation of malic acid.

The most remarkable fact shown by table IV is the great influence exerted by salts of barium and calcium, especially when it is remembered that in equal equivalent concentrations there is only half an atom of these elements present to one atom of the alkalis. In order to determine whether this influence was connected with the valency of the metallic radicle, as well as to further the investigation generally, the effect of salts of other bivalent metals, and of the trivalent metal, aluminium, was measured.

Effect of Salts of Weaker Bases.

TABLE VI.

The curves in Fig. 2 show the respective effects of all the various chlorides used; also of cadmium nitrate, cadmium chloride not being used.

The effects of the salts mentioned in the above table is in general positive, and of the same order as that of the alkali and alkaline earth salts, although less in magnitude. It follows that the large influence of barium and calcium salts is not merely dependent on the valency of the metal. As was found in previous cases, so in table VI it is seen that the chloride and nitrate of any particular metal (with a notable exception, to which reference will be made later, in the case of mercury) exert about the same influence on the rotation, and the sulphate considerably less than either. The general effect of the metal radicles is in the order

More complicated relationships have, however, replaced the simple ones met with in the case of the alkali salts; so that to draw with any accuracy the curves representing the effects, more points than two or three would usually need to be determined. In every case previously studied, the effect when $n=1$ is less than four times

FIG. 2.

that when $n=\frac{1}{4}$, and the corresponding curve is convex upwards. This still holds for magnesium chloride and magnesium nitrate but for the other salts in table VI, and notably those of zinc and mercury, the reverse is true. A striking illustration is the case of zinc sulphate, where the effect when $n=\frac{1}{4}$ is actually zero, the when $n=1$ being more than a degree. It thus appears that the

first addition of zinc sulphate produces a negative effect, making the rotation more *levo*; and that as further quantities are added, the influence attains a negative maximum, passes again through zero, and becomes positive. The case of mercuric nitrate, if comparable, is more remarkable still. The figures (for $n = \frac{1}{2}$, $\Delta = -3.36^\circ$, and for $n = 1$, $\Delta = -3.58^\circ$) suggest that the initial large negative influence reaches a maximum between the two concentrations studied, and that further additions of salt would probably influence the rotation in a *dextro*-sense.

The cause of the greater complexity of the influence of these salts is doubtless connected with their being salts of much weaker bases than those previously studied, the complexity of the influence increasing with the weakness of the base. The incipient formation of feebly dissociated salts or complexes of malic acid appears a probable explanation. Malic acid is noted for its tendency to form with weakly basic metals complexes of a widely different rotation from the acid itself. On the addition to the acid of a salt of a weak base, a limited amount of the feebly dissociated malate or complex would be formed, and equilibrium set up according to the equation:

Thus, as actually observed, the initial addition of salt would affect the rotation in an anomalous manner, depressing its value if the malate or complex formed were strongly *levorotatory*; whilst further additions would affect it more normally. To test this explanation, a rough experiment was performed in the case of the "n = 1" solution of zinc nitrate and malic acid (table VI), nitric acid being added in successive small equal quantities to the solution, and its effect on the rotation observed. If the above explanation be correct, the first additions of nitric acid should diminish the amount of the feebly dissociated malate or complex, according to the equation, and thus influence the rotation more powerfully in a *dextro*-direction than subsequent additions, the effect of which would be only the ordinary one of acids on malic acid (see table VIII). That this actually occurred, the following table shows:

TABLE VII.

No. of parts of nitric acid added,	Observed angle of rotation.
0	0.71"
3	0.38
7	1.19
13	1.33
23	1.54

Effect of Acids.

TABLE VIII.

Acid.	n.	α_D^{20} .	α_D^{25} .	$[\alpha]_D^{20}$.	$[\alpha]_D^{25}$ for pure acid.	λ
HCl	$\frac{1}{2}$	1.0875	-0.105*	-0.25*	-0.97	0.7

C ₂ H ₃ O ₂	1	1.0855	-0.304	-0.78	-1.09	1.1

Schneider (*Annalen*, 1881, 207, 278) investigated the effect of sulphuric and acetic acids on a considerably weaker solution of malic acid than that employed in the present research, and found that both changed the rotation in a dextro-sense, the former, however, tenfold more so than the latter. The measurements tabulated above for these acids are in harmony with his result. Acetic acid exerts a regular and positive, but notably small, influence, a fact to which future reference will be made.

Some small part of the influence of the acids must be due to the throwing back the small electrolytic dissociation of the malic acid, but it is as hydrogen salts that they have their chief effect. The latter is, for the mineral acids, regular and somewhat smaller than that of the alkali salts. Hydrochloric acid exerts a less influence than lithium chloride, so that in order of influence $K > Na > Li > H$ parallel to the order of atomic weights. Nitric acid has less influence than hydrochloric acid, as was to be expected; but sulphuric acid breaks the usual order, $Cl > NO_3 > \frac{1}{2}SO_4$, in that it lies between hydrochloric and nitric acids in its effect. The explanation of the exception is not clear; it may possibly be due to the fact that HSO_4 ions are largely present instead of the SO_4 ions in other sulphuric solutions.

Effect of Salts on Solutions of Varying Concentration.

Hitherto the influence of electrolytes has been considered on the specific rotation of 20 per cent. solutions of malic acid only. It was thought of interest to determine how that influence varied, both absolutely and relatively, with respect to different salts when the concentration of the acid was varied. For this purpose the effect of potassium chloride and of sodium chloride was studied on 5 per cent. and 40 per cent., as well as on 20 per cent. solutions of malic acid. In table IX, γ =percentage of malic acid solution; n =number of equivalents of salt added per 100 grams of pure malic acid; other symbols have their usual meaning.

TABLE IX.

Salt.	<i>p</i> .	<i>n</i> .	d_D^{20} .	α_D^{20} .	$[\alpha]_D^{20}$.	$[\alpha]_D^{20}$ for pure acid. (a.)	Δ .
KCl	5	$\frac{1}{2}$	1.0235	-0.161*	-1.59*	-2.25*	0.66*
KCl	5	1	1.0405	-0.034	-0.34	-2.25	1.91
KCl	5	4	1.1043	0.335	3.50	-2.25	5.75
KCl	5	$\frac{1}{2}$	1.023	-0.183	-1.81	-2.25	0.44
NaCl	20	$\frac{1}{2}$	1.1013	0.455	1.07	-0.88	1.95
KCl	20	$\frac{1}{2}$	1.0993	0.30	0.70	-0.97	1.67
NaCl	40	$\frac{1}{2}$	1.2132	3.573	3.96	0.535	3.425
KCl	40	$\frac{1}{2}$	1.2083	3.417	3.74	0.535	3.205

(a) For this column see table I.

(b) These figures are taken from table II.

The relative effect of equivalent quantities of potassium chloride and sodium chloride is seen to be about the same for each strength of acid solution, in each case potassium chloride exercising somewhat more influence than sodium chloride. A similar result may be inferred to hold for the influence of salts generally.

The values of Δ given for the three different concentrations of potassium chloride in the case of 5 per cent. acid solutions show the regularity of the influence exerted, even when (as for $n=4$) the molar concentration of the salt considerably exceeds that of the acid. If these values are considered along with the other results obtained for potassium chloride (tables II and IX) a simple and important relation is seen to obtain between Δ and the potassium chloride concentration of the solutions examined. Let N denote the number of equivalents of potassium chloride per 100 c.c. of solution (p and Δ same as before); then, with the necessary calculations, the following is obtained:

TABLE X.

<i>p</i> .	<i>N</i> .	Δ .
5	0.0128	0.66*
5	0.052	1.91
5	0.221	5.75
20	0.0273	1.04
20	0.055	1.95
20	0.112	3.49
20	0.232	5.57
40	0.121	3.425

It is evident that Δ depends mainly on N , and but little on p ; in other words, the influence of the salt on the specific rotation depends mainly on the concentration of the solution with regard to that salt, and not on the concentration of malic acid present. Each malic acid molecule may be regarded as affected independently of other malic acid molecules, but to a degree dependent on the

number of salt molecules or ions within its sphere of influence. What little departure the above table shows from this rule is explicable by the varying malic acid present causing a variation in properties of solvent and salt, for example, by affecting the degree of dissociation. It may be mentioned that Farnsteiner's work on the influence of salts on the rotation of sucrose reveals a quite analogous law (*Ber.*, 1890, **23**, 3750).

Effect of Salts of Weak Acids.

It has been calculated above (p. 2266) that the action of malic acid on salts of strong bases and strong acids is negligible. This would not, however, hold in the case of a salt of a weak acid. It was thought of interest to determine the effect in one or two cases of an acetate, which is the salt of an acid weaker even than malic.

TABLE XI.

Salt.	<i>n</i> .	a_1^{20}	a_2^{20}	$\{a\}_s^{20}$	$\{a\}_s^{20}$ for pure acid.	Δ
KC ₂ H ₃ O ₂	1	1.1000	-0.762	-1.82	-0.95	-0.87
KC ₂ H ₃ O ₂	1	1.1310	-2.216	-5.74	-0.95	-4.79
Ba(C ₂ H ₃ O ₂) ₂	$\frac{1}{2}$	1.1235	1.25	2.98	-0.97	-3.95
Ba(OH) ₂	0.2435	1.1195	1.069	2.49	-0.97	-3.48

For " $n = \frac{1}{2}$ " concentration, potassium acetate gave an effect of -0.87° , as against $+1.95^\circ$ for potassium chloride. This negative effect (in contrast with the case of mercuric nitrate) was more than quadrupled on quadrupling the amount of salt added. The contrast between the influence of potassium acetate and that of other potassium salts is explained by the large formation in the former case of hydrogen malate and undissociated acetic acid. The extent and effect of this action may be approximately calculated for the " $n = \frac{1}{2}$ " addition of potassium acetate. In the following scheme the symbols mean the same as in the somewhat similar calculation on p. 2266.

Let k_1 and k_2 be the respective dissociation constants of malic and acetic acids, and C the concentration of hydron in solution. The following well-known relations will hold:

$$C \times \{a_1(1-x) + a_3x\} = k_1 \times (1-a_1)(1-x) \quad (i)$$

$$\text{and} \quad C \times \{a_2(n-x) + a_4x\} = k_2 \times (1-a_2)x \quad (ii)$$

$$\therefore \text{by division,} \quad \frac{a_1(1-x) + a_3x}{a_2(n-x) + a_4x} = \frac{k_1(1-a_1)(1-x)}{k_2(1-a_2)x} \quad (iii)$$

Now a_2 may be taken approximately equal to a_3 ; and a_1 , and particularly a_4 , are very small. Also, $k_1 = 3.95 \times 10^{-4}$, $k_3 = 1.8 \times 10^{-3}$. Hence, equation (iii) reduces approximately to:

$$x^2 = \frac{395}{18} (1-x)(n-x).$$

Now, as in the former calculation, $n = 0.335$.

$x = 0.3263$; that is, $\frac{0.3263}{0.335}$ or 97.4 per cent. of the potassium

acetate has been acted on and hydrogen malate formed.

An estimate may now be made of the order of the rotation the solution might be expected to show. The rotation should mainly consist of (a) the rotation of the potassium hydrogen malate, (b) that of the excess of untransformed malic acid, and (c) the influence of the potassium hydrogen malate and acetate, similar to that of other salts, on the rotation of the excess of malic acid. For (a), interpolation from the data of Schneider (*Annalen*, 1881, 207, 266), with necessary calculation, gives -0.99° as the actual rotation of 240 mm. of a solution of potassium hydrogen malate of the same concentration as has been calculated to be present above. For (b), similar interpolation and calculation from the author's data in table I give -0.41° as the rotation caused by the residual unchanged malic acid (amounting to 67.4 per cent. of the whole). For (c), assuming the influence to be approximately equal to that of an equivalent quantity of potassium chloride, calculation gives 0.55° . Adding these three effects, the observed rotation α of the solution should thus be about $-0.99^\circ - 0.41^\circ + 0.55^\circ = -0.85^\circ$. The angle actually observed was -0.76° . The agreement between the results of calculation and observation is at least sufficiently good to show that the abnormal negative influence of potassium acetate, and even its order of magnitude, might have been anticipated.

Barium salts (table IV) exert so large an influence on the rotation of malic acid that the question suggests itself whether here, at least, the formation of a chemical complex or undissociated salt is accountable. Considering the strongly basic nature of barium, such a thing is a priori improbable; yet the large influence referred to, considered in conjunction with the extraordinarily sharp ascent to a large dextrorotation determined by Schneider for barium malate, even in dilute solution (*loc. cit.*, p. 277), makes it desirable to answer the question with greater certainty. The results for the addition of barium acetate and barium hydroxide, tabulated above, enable this to be done. If a complex or feebly dissociated malate were formed, a much greater effect would be expected in these cases than when the hydrochloric acid is competing for the barium. Tables IV and XI show, however, that, on the contrary, and as in

the case of potassium acetate, the acetate and hydroxide of barium cause considerably less dextrorotation than the chloride.

The table shows that barium hydroxide was added in somewhat smaller proportions than the barium acetate, in fact, so as to produce in solution the amount of barium hydrogen malate which a calculation similar to that made in the case of potassium acetate would show to be formed when the barium acetate was added. As would be expected if the apparent influence of the acetate were due to an almost complete formation of hydrogen malate, the effect of the barium hydroxide was only a little less than that of the barium acetate. The difference of 0.49° is to be explained by (i) the slightly greater amount of barium in the latter case influencing the rotation of the unchanged malic acid by 0.1° to 0.2° ; (ii) the one fourth equivalent of acetic acid present in the latter case exercising (see table VIII) a small effect on the rotation, say, 0.1° ; (iii) the more dilute solution in the former case, due to the water of neutralization; this would rather lower the observed rotation.

Effect of Electrolytes on Malates.

Thomsen (*J. pr. Chem.*, 1887, [ii], 35, 145) found that excess of alkali had a considerable influence on the rotation of alkali salts of malic and other hydroxy-acids, which he ascribed to the formation of complexes, the excess of alkali combining with the alcoholic hydroxyl. The evidence offered in support does not seem strong, no such complex being prepared, and the main argument apparently being the observed effect on the rotation. It seemed worth investigating whether sodium chloride affected sodium malate similarly to excess of sodium hydroxide. The solutions were prepared of such strength that they may be considered to consist of 20 per cent. malic acid solution, together with the amount of anhydrous sodium hydroxide or chloride required for the equivalent proportions. In the following table, $[\alpha]_D^{20}$ is calculated as the specific rotation of the malic acid present; Δ is the positive increase in $[\alpha]$ due to addition of the extra sodium hydroxide or chloride molecule.

TABLE XII.

Equivalent proportions.	α_D^{20} .	α_D^{20} .	$[\alpha]_D^{20}$.	Δ
$C_4H_5O_6 + 2NaOH$	1.171	-3.128*	-7.46*	—
$C_4H_5O_6 + 3NaOH$	1.2226	-1.524	-3.67	3.79
$C_4H_5O_6 + 2NaOH + NaCl$	1.2172	-2.006	-4.97	2.49
* $C_4H_5O_6 + 2NaOH$	1.1716	—	-7.42	—
* $C_4H_5O_6 + 3NaOH$	1.2222	—	-3.71	3.71

* The last two lines are obtained by interpolation and calculation from Thomsen's results; they agree well with the author's data, in the first two lines.

It appears that sodium chloride produces a dextro-effect on the rotation about two-thirds of that produced by sodium hydroxide; thus the influence is at least of the same order; and if, as seems likely, the influence of sodium chloride is not due to a complex, it cannot be said, apart from further evidence, that the influence of sodium hydroxide is so caused. Other substances than sodium hydroxide would presumably similarly influence the rotation of sodium malate. It is interesting to note that, if two molecules of sodium chloride had been first added to the 20 per cent. malic acid instead of two of sodium hydroxide, the third molecule of sodium chloride would, by extrapolation from the results in table II (if such extrapolation can be trusted), have an influence on the rotation of approximately the same magnitude, 2.5° ; at any rate, not more.

Discussion of Results and Conclusions.

Inactive electrolytes might influence the rotation of a solution of malic acid in two ways: (i) by affecting the composition or constitution of the active molecules; (ii) by setting in operation solution-forces which would affect the asymmetry of the molecules. Change in composition might come about, in the first place, by the salts forming complexes with the malic acid, an explanation which, with a possible exception in the case of a few of the salts of table VI, may on the following grounds be dismissed as most improbable: (a) the regular nature of the salt influence; (b) the *a priori* inconceivability of a salt like potassium chloride forming such complexes; and (c) the evidence already given against complex formation in the case of barium chloride. Secondly, the malic acid might act on the salts, forming malates and liberating acids; but calculation, confirmed by experiment, has shown that this only occurs to an extent of any importance when the salt of a weak acid, such as acetic, is added; thus, in a solution of malic acid and potassium chloride, the partial formation of potassium hydrogen malate, which is levorotatory (Schneider, *loc. cit.*, p. 266), could not explain the large dextro-influence observed. Thirdly, change of molecular composition might be due to change of electrolytic or other dissociation in the presence of the salts; but the magnitude of the effects observed is far too great to be explained by change of electrolytic dissociation, whilst it appears highly improbable that polymerisation would be largely influenced by the presence of the salts.

The cause of the salt-influence must, then, be sought elsewhere than in change of composition or constitution of the active substance. An explanation plausible at first sight is that the formation in solution of hydrated molecules by the added salts

would act like concentrating the solution, which is well known to influence the rotation of malic acid in a dextro-sense (Schneider *loc. cit.*, p. 262). That such an action, if occurring at all, is relatively insignificant, is shown (i) by the fact that the magnitude of the salt-influence is often far too great to be thus explained; barium chloride, for example, producing at the higher concentrations an effect several times as great as would be given by total dehydration of the malic acid (assuming Schneider's value of 5.93° for the rotation of the anhydrous acid); (ii) by the fact that, in general, the salts with greatest affinity for water, such as lithium chloride, actually exercise the least influence.

Light would be thrown on the salt-effects could a parallelism be discovered between them and any other physical properties of the solutions. The result of a search made by the author for such a parallelism may be summarised as entirely negative; this applies not only to purely physical properties, such as viscosity and density of the solutions, mass of salt added, etc., but also to the physical-chemical action of salts in precipitating colloids, and their influence on the solubility of non-electrolytes in water (Rothmund, *Leichtlichkeit und Löslichkeitsbeeinflussung*, p. 148). It is especially noteworthy that the internal pressure of aqueous solutions of the various salts (see Tamman, "Beziehungen zwischen den inneren Kräften und Eigenschaften der Lösungen," p. 87) shows no significant parallelism to the effects of the salts on the rotation of malic acid. This fact bears on Patterson's attempt (Trans., 1901 and following years) to establish a general connexion between the "solvent influence" on rotation and the internal pressure of the solutions.

The above failure to connect the observed effects of electrolytes on the rotation of malic acid with ordinary chemical or physical changes confirms the view that the influence is mainly due to a direct and distinctive power possessed by the inactive molecules in solution to affect the asymmetry of the active ones within their sphere of influence without actual chemical combination. The is deduced on p. 2277 that "the influence of the salt on the specific rotation depends mainly on the concentration of the solution with regard to that salt, and not on the concentration of malic acid," this receives its explanation. Further, (i) from the additive nature of the effect of strong positive and negative radicles (p. 2277); (ii) from the smallness of the effect of mercuric chloride and acetic acid, the two practically non-ionised substances used; (iii) from the parallelism between unexpectedly low influence and low conductivity in the case of barium nitrate; and (iv) from the consideration that most of the properties of solutions of electrolytes are actually

mic, it is reasonable to conclude that the large effects tabulated in this paper are chiefly produced by the ions.

The nature of this ionic influence can be little more than guessed. For positive univalent ions the influence is in the order of the electro-affinities in aqueous solution, thus:

but for negative univalent ions the reverse is the case, thus: $\text{Br} > \text{Cl} > \text{NO}_3$. Passing to bivalent ions, this parallelism is broken. $\frac{1}{2}\text{Ba}$ and $\frac{1}{2}\text{Ca}$ have an influence greatly exceeding that of the more positive Cs; and $\frac{1}{2}\text{SO}_4$ less than that of the more negative NO_3 . The unexpected place that sulphuric acid was seen to occupy in the order of influence of acids may be due to the bivalent HSO_4 ions affecting the rotation much more than SO_4 ions. With the exception, however, of cadmium, which is between zinc and mercury in its electro-affinity, the bivalent metal ions show among themselves a similar parallelism, thus:

The connexion between electro-affinity and ion-influence is striking. As for the mode of the influence, it appears plausible that it may be connected with the sensitiveness of the alcoholic hydroxyl of malic and other hydroxy-acids, which is liable to be attacked with the formation of complexes showing unusually large rotation. Though within the sphere of influence of a malic acid molecule may be the centres of forces which, acting on the sensitive hydroxyl group, change the asymmetry or rotatory power of the molecule, this is the point of influence, malic anions ought to be similarly sensitive to ionic influence—an expectation confirmed by facts (see 22-1). It is worthy of note that when the hydroxyl group had been attacked and a chemical complex formed, Rosenheim and Ber. (1899, 32, 3432) found that the great sensitiveness of malic acid to changes of concentration disappeared.

If the above view is correct, light is thrown on the general nature of the often otherwise inexplicable influence of solvents on rotation. Without any change of molecular composition or constitution (as usually understood), the interaction of the "residual affinities" of molecules of solute and solvent may affect the degree of asymmetry of the former, just as malic acid molecules are influenced by neighbouring ions in aqueous solution.

Of special interest on the above data and discussion has to be mentioned. Schneider (*Annalen*, 1881, 207, 257) measured the specific rotation, $[\alpha]_D^{20}$, in aqueous solutions of various concentrations of malic acid, the malates and hydrogen malates of potassium, sodium, lithium and ammonium, and barium malate.

He found the specific rotation of malates to vary with the concentration, even more than that of malic acid. Moreover, the diversity of rotation shown by the various malates (see his diagram, *loc. cit.*, facing p. 368) is not merely due to his plotting specific rotation against percentage compositions of the solution, for when calculations are made from his data, and molecular rotations plotted against molar concentrations, the diversity persists in a no less striking form. This might be expected at higher concentrations of dissolved salt, where the influence of the metallic radicals in the undissociated molecules is naturally felt. The interesting fact is that at lower concentrations the differences in molecular rotation of the various salts persist in such a way that only the bare approximation holds to Oudemans' law, namely, that salts of an active acid and inactive base show the same molecular rotation in very dilute solutions. Schneider's data for barium malate do not allow of extrapolation of any accuracy; the following table shows the values given by him (*loc. cit.*, p. 284), by extrapolation from an empirical formula, for the molecular rotations at infinite dilution of the alkali malates.* The last column shows the corresponding values obtained by the author from graphical extrapolation.

TABLE XIII.

Malate of	$[M]_D^{20}$ at inf. dilution (Schneider).	$[M]_D^{20}$ at inf. dilution (graphically).
KH	-10.65*	-10.4
NaH	-10.95	-11.0
LiH	-11.87	-12.5
K ₂	-15.35	-15.5
Na ₂	-17.52	-16.2
Li ₂	-18.56	-19.2

The above table shows beyond doubt that, according to Schneider's results, Oudemans' law is only approximately obeyed. In the case of both malates and hydrogen malates, the molecular rotation at infinite dilution of the potassium salt is more dextro than that of the sodium salt, and the latter than that of the lithium salt. The order of effect remarkably parallel to that given for the salts in table II, namely $K > Na > Li$. On the view which the author has taken, the explanation is simple. The metallic ions of the dissociated malates retain the power to influence the asymmetry of the malic anion, just as the ions of salts have been seen to affect malic acid molecules and anions (tables II and XII). At infinite dilution this influence persists, for, unlike the case in which the ions of electrolytes influence malic acid molecules by their chance proximity

* Owing to hydrolysis probably commencing at low concentrations, the effect for the malate of the weak ammonium are not very significant.

the positively charged cations must by electrostatic forces be kept always within the sphere of influence of the negatively charged active anions. Hence if alkali cations influence the rotation of malic or hydromalic anions in the same order ($K > Na > Li$) as they influence the undissociated molecules, just such deviation from Oudemans' law would be expected as actually observed. It may be added that the rapidly increasing dextrorotation of barium malate is probably due (in part, at least) to the influence on the malic anions of the barions, which have been seen (table IV) to have an extraordinarily great influence on malic acid itself.

If the above view of the invalidity of Oudemans' law in this case is correct, it is evident that colorimetric and other discrepancies cited against the ionic hypothesis may really be an indication of a similar continued mutual influence of the dissociated ions.

The influence of the alkali salts on the rotation of malic acid shows a regularity hitherto unmentioned. In general, the rate of the initial influence of a salt is not sustained, but falls off as its concentration increases. The regularity referred to consists in the fact that the rate of influence of the alkali chlorides, for example, falls off more rapidly the higher the atomic weight of the metal. This is shown in Fig. 2 by the increasing curvature of the curves from lithium chloride to cesium chloride. No explanation of this behaviour has been found.

In conclusion, it may be said that a systematic confirmation and extension of some of the older work on malic acid and malates seems called for, using purer materials, more accurate instruments, etc. The determination, in very dilute solutions, of the rotation of malates, their electrolytic dissociation, and the effect of various salts on their rotation, would be a valuable contribution to the subject.

Finally, the author is of the belief that electrolytes will exercise a similar influence on tartaric and other hydroxy-acids—a matter perhaps worthy of investigation.

Summary.

(1) Certain other workers (especially Schneider and Woring) appear to have erred in the determination of the strength of their malic acid solutions, and their data need revision accordingly.

(2) Electrolytes in general exercise a large influence on the rotation of malic acid solutions, turning it in a dextro-direction.

(3) This influence is mainly a specific additive property of the radicals or ions; it is notably great in the case of alkaline earth salts; and it appears to be related with the valency of ions and their order of electro-affinities.

(4) The influence of electrolytes is shown not to be in general due to complex-formation or ionic reaction, or to hydrate formation by the electrolytes.

(5) The asymmetry of the malic acid molecules is affected by the ions within their sphere of influence, to an extent dependent on the concentration of electrolyte, and not largely on that of malic acid. No connexion has been found with other properties of electrolyte solutions.

(6) Thomsen's supposed complex-formation between sodium malate and excess of alkali appears explicable on the ground of similar ionic influence on the malic anions.

(7) The divergencies of the alkaline malates (according to Schneider's data) from obeying Oudemans' law appear explicable on the ground of the continued influence of the dissociated or necessarily adjacent ion; (the same may hold for other apparent contradictions of the ionic hypothesis).

The author desires to express his indebtedness to Professor F. G. Donnan, whose suggestions and advice were invaluable throughout the course of the work.

CCLIII.—Organic Derivatives of Antimony. Part II *The Orienting Influence of Antimonic Substituents in the Benzene Nucleus.*

By GILBERT T. MORGAN and FRANCES M. G. MICKLETHWAIT

PHOSPHORUS, arsenic, and antimony differ markedly from nitrogen, the initial member of this periodic family of elements, in regard to the degree of hydration exhibited by their oxy-acids, and this difference persists in the organic derivatives of these acids. Nitric acid, which yields metallic salts derived from the meta-hydrate $\text{HIO} \cdot \text{NO}_2$, gives rise to organic nitro-compounds corresponding exclusively with its least hydrated form. On the contrary, the organic derivatives of phosphorus, arsenic, and antimony, like the metallic salts of the oxy-acids of these elements, exhibit types corresponding with the more hydrated pyro- and ortho-acids, as well as compounds derived from the meta-acids.

Accordingly these three elements can each furnish three series

of compounds derived from their ortho-oxy-acids, as illustrated in the following scheme, where X is phosphorus, arsenic, or antimony, and R a univalent alkyl or aryl group:

Some of the compounds of the third series are found to exist in the hydrated form, $\text{R}_3\text{X}(\text{OH})_2$, which corresponds with the true ortho-hydrate, $\text{X}(\text{OH})_3$.

When substitution occurs in nitrobenzene the introduction of the entrant substituent follows the meta-law of substitution. Nitration and sulphonation, for example, lead mainly to the production of a dinitrobenzene and nitrobenzene-*m* sulphonic acid. In this respect the nitro-group is analogous to the carboxyl and sulphonic groups, which are similarly derived from meta-acids:

meta-Acids.	Phenyl compound.	1:3-Di-derivative.
$\text{HO}\cdot\text{NO}_2$	$\text{C}_6\text{H}_5\cdot\text{NO}_2$	$\text{C}_6\text{H}_3(\text{NO}_2)_3$
$\text{HO}\cdot\text{CO}_2\text{H}$	$\text{C}_6\text{H}_5\cdot\text{CO}_2\text{H}$	$\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{CO}_2\text{H})$
$\text{HO}\cdot\text{SO}_3\text{H}$	$\text{C}_6\text{H}_5\cdot\text{SO}_3\text{H}$	$\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{SO}_3\text{H})$

This being the behaviour of meta-acidic groups in reactions involving substitution, it becomes of interest to ascertain what law of substitution is followed in the presence of such acid groups as $\text{XO}(\text{OH})_2$, $\text{XO}\cdot\text{OH}$, and $\text{X}\cdot\text{O}$ or $\text{X}(\text{OH})_2$.

Although a very large amount of work has been carried out, chiefly by Michaelis and his pupils, on aromatic compounds containing phosphoric, arsenic, and antimonious substituents, yet the influence of these groups on the orientation of entrant radicles has not been studied systematically; for example, in the phosphorus series it is surmised that, in nitrophenylphosphinic acid, the nitro-group occupies a meta position with respect to the phosphoric radicle (Michaelis and Benzinger, *Annalen*, 1877, **188**, 273), but in the case of trinitrotriphenylphosphine oxide the nitro-groups are assumed to take up para-positions (Michaelis and Soden, *Annalen*, 1885, **229**, 326). Some uncertainty still exists in regard to the arsenic series, although recent researches on atoxyl and allied compounds have shown that the nitration product of phenylarsinic acid is the meta-compound (Michaelis and Lösner, *Ber.*, 1894, **27**, 203; Berthelm, *ibid.*, 1908, **41**, 1655; 1911, **44**, 3297).

The organic antimony derivatives have recently acquired importance owing to the belief that some of these substances might prove to be of therapeutic interest. The present communication deals mainly with the nitration of the three series of antimony compounds and with the orientation of the products.

(1) *Monophenyl Series*.—An interesting point has arisen in connexion with the preparation of phenylstibine dichloride, the starting point in this series. The dichloride was first prepared by Hauerbäumer (*Ber.*, 1898, **31**, 2910) by heating triphenylstibine and antimony trichloride in xylene at 240°. In a recent communication Michaelis and Günther (*Ber.*, 1911, **44**, 2316) state that this reaction leads to the formation of diphenylstibine chloride, which they isolated in comparatively poor yield. We find that both these observations are correct, our experiments showing that the condensation is a balanced reaction in the sense indicated by the following equations:

Phenylstibine dichloride, which according to our experience is the main product of the foregoing change, yields phenylstibinic acid on successive chlorination and hydrolysis. The nitration product of this acid consists chiefly of *m*-nitrophenylstibinic acid, for on heating at 110–120° with phosphorus pentabromide (3 mols.) the antimonious group is eliminated, and 1-bromo-3-nitrobenzene is produced:

This result might have been predicted by applying the Crum Brown and Gibson rule. The hydrogen derivative of the antimonious substituent is $\text{H}\cdot\text{SbO}(\text{OH})_2$, assuming this to be a possible form of antimonious acid. Now since this acid is directly oxidisable to antimonious acid, the corresponding radicle, $\cdot\text{SbO}(\text{OH})_2$, like the NO_2 and CO_2H groups, should induce substitution in the meta-position. The groups $\cdot\text{SbO}\cdot\text{OH}$ and $\cdot\text{SbO}$ or $\cdot\text{Sb}(\text{OH})_2$ are present in the diphenyl and triphenyl series, and since the corresponding hydrogen compounds are unknown, it is impossible to predict what would be their behaviour towards oxidising agents. Accordingly the rule cannot be applied to these cases.

(2) *Diphenyl Series*.—The nitration product of diphenylstibinic acid is rather more stable than *m*-nitrophenylstibinic acid and the trinitro-derivative of triphenylstibinic acid, but on heating at 150–160° with phosphorus pentabromide (2 mols.) and bromine (1 mol.) it undergoes fission into antimony bromide and 1-bromo-3-nitrobenzene:

The group $\text{SbO}\cdot\text{OH}$ accordingly induces substitution of a NO_2 radicle in the *meta*-position.

(3) *Triphenyl Series*.—Triphenylstibinic acid (triphenylstibine dihydroxide) furnishes a trinitro-derivative, which is proved to be chiefly the *meta*-compound by fission at 110° with phosphorus pentabromide (2 mols.) and bromine (2 mols.):

The 1-bromo-3-nitrobenzene collected was about 70–80 per cent. of the calculated quantity.

In the triphenyl series it is of interest to note that intermediate nitration products can be isolated when less concentrated nitric acid is employed. Triphenylstibine nitrate and hydroxynitrate have both been described, and it is therefore probable that the first stage of nitration in these three series of stibinic acids is the formation of nitrates, the nitro-group becoming first attached to an oxygen of the antimonious substituent, and subsequently migrating into the ring in the *meta*-position, this process being repeated until each phenyl group present is nitrated:

Cases in which the migrating group passes from the side-chain to a *meta*-position in the ring are very uncommon, but an interesting comparison may be drawn between the foregoing nitrations and the transformation of benzoyl nitrate into *m*-nitrobenzoic acid:

(Francis, *Ber.*, 1906, **39**, 3798). The production of *m*-nitroaniline from aniline nitrate and concentrated sulphuric acid may be regarded from a similar point of view:

EXPERIMENTAL.

Triphenylstibine, the starting point of this investigation, was first prepared by Michaelis and Reese in the interaction of antimony

trichloride, chlorobenzene, and sodium in dry benzene (*Ann.*, 1886, **233**, 39), and since produced by Pfeiffer through the Grignard reaction (*Ber.*, 1904, **36**, 4620), the yield being about 60 per cent of the weight of trichloride employed.

The following modified process gave an almost quantitative yield of this substance. A 10 per cent. benzene solution containing 18 grams of antimony trichloride was slowly added to the Grignard reagent prepared from 50 grams of bromobenzene and 700 grams of powdered magnesium suspended in dry ether, and the mixture boiled for six hours and then distilled in steam. The inorganic residue was freed from diphenyl hy extraction with small quantities of cold alcohol, and the undissolved triphenylstibine (m. p. 48°) was further purified by crystallisation from hot alcohol, although this treatment was not generally necessary.

A similar result was obtained by using antimony tribromide, by the sparing solubility of this halide in benzene necessitated the employment of more dilute solutions.

If in these condensations with antimony trichloride or tribromide the benzene solution is filtered from the precipitate of magnesium compounds and worked up without distillation in steam, the product consists in part of triphenylstibine dichloride or dibromide but these compounds of quinquevalent antimony are converted into triphenylstibine by reduction with alcoholic ammonium sulphide as recommended by Kaufmann (*Ber.*, 1908, **41**, 2762).

The nitration experiments were carried out on triphenylstibine hydroxynitrate, a compound already described as resulting from the interaction of triphenylstibine dichloride and silver nitrate (*Trans.*, 1910, **97**, 35). This crystalline hydroxynitrate can also be prepared by adding triphenylstibine to a 30 per cent. solution of fuming nitric acid in glacial acetic acid. Nitrous fumes are evolved, and after the violent reaction has subsided, the liquid is gently warmed and poured into water. The crystals of hydroxynitrate melts at 220°.

Twenty-five c.c. of nitric acid (D 1.5) decolorised with carbamide were mixed with 6 c.c. of concentrated sulphuric acid and maintained at 40° while 3 grams of the hydroxynitrate were slowly added, the temperature being afterwards raised to 55°. After two hours the cooled solution was poured on ice, the precipitated nitro-compound dissolved in warm *N*-sodium hydroxide, and reprecipitated by hydrochloric acid.

Tri-m-nitrotriphenylstibinic acid is a pale orange-yellow powder. It is precipitable from glacial acetic acid in light yellow leaflets. Its decomposition point is somewhat indefinite, ranging in different preparations from 170° to 191°. This variation is possibly due to the presence of varying amounts of para- and ortho-isomerides. The compound is, however, identical with the substance obtained by May on nitrating triphenylstibine (Trans., 1910, **97**, 1958), this being demonstrated by comparative experiments on the two methods of preparation.

The alkali salts of tri-*m*-nitrotriphenylstibinic acid are soluble in water to a brownish-orange solution, which on boiling acquires an odour of nitrobenzene. The barium, strontium, calcium, magnesium, copper, silver, cobalt, and lead salts obtained by double decomposition from the soluble alkali and ammonium salts are all sparingly soluble.

Orientation Experiments with Tri-m-nitrotriphenylstibinic Acid.

Preliminary trials with aqueous potassium hypobromite showed that the acid is oxidised destructively by this reagent. Heating with iodine chloride in glacial acetic acid solution effected the elimination of antimony, but the mixed iodo- and chloro-derivatives of nitrobenzene which were simultaneously produced could not be separated and identified.

(1) One gram of tri-*m*-nitrotriphenylstibinic acid was heated for twelve hours at 115—130° with 15 c.c. of chloroform saturated with hydrogen bromide. The contents of the tube were distilled in steam, but no nitrobenzene could be detected. This experiment, which was duplicated, showed that hydrogen bromide alone did not decompose the nitro-compound into antimony tribromide and nitrobenzene.

(2) A sealed tube containing 1 gram of nitro-acid, 2 grams of phosphorus pentabromide, and 1 gram of bromine in 15 c.c. of chloroform was heated at 130—160°, and although some charring occurred, the yield of 1-bromo-3-nitrobenzene was 70 per cent. of the calculated quantity.

(3) One gram of nitro-acid and 3 grams of bromine heated in chloroform at 115—130° gave on distilling in steam 0.7 gram of 1-bromo-3-nitrobenzene, and 0.25 gram of the unchanged nitro-compound was recovered; the eliminated antimony was precipitated and weighed as sulphide, the calculated amount being obtained.

(4) Experiment 2 was repeated, using dry sodium tri-*m*-nitrotriphenylstibinate instead of the free acid, and adding triethylamine to fix the hydrogen bromide produced during the decomposition. The contents of the tube were distilled in steam, when the only volatile product obtained was 1-bromo-3-nitrobenzene.

(5) Two grams of tri-*m*-nitrotriphenylstibinic acid, 5 grams of bromine, and 15 c.c. of water were heated for several days at 160°, and then for twenty-seven hours at temperatures ranging from 150° to 270°. The product when freed from excess of bromine and distilled in steam yielded 1.2 grams of 1-bromo-3-nitrobenzene, and the residue gave 0.3 gram of brominated product, probably 1:3:4-tribromo-5-nitrobenzene (m. p. 119°).

(6) The crude tri-*m*-nitrotriphenylstibinic acid when boiled with excess of *N*-sodium hydroxide furnished a small amount of nitrobenzene arising probably from the hydrolysis of the para and ortho-isomerides of this acid, which are not present to the extent of more than 10 per cent.

Tri-m-aminotriphenylstibine, $\text{Sb}(\text{C}_6\text{H}_4\cdot\text{NH}_2)_3$.

Two grams of tri-*m*-nitrotriphenylstibinic acid were slowly introduced into 100 c.c. of boiling alcohol containing 5 grams of zinc dust and 0.8 gram of ammonium chloride. The mixture was heated and shaken for half an hour, and then filtered into 100 c.c. of ice-cold water. The precipitated base was dissolved in dilute hydrochloric acid, and the tri-*m*-aminotriphenylstibine set free by ammonia:

0.1858 gave 0.3727 CO_2 and 0.0811 H_2O . $\text{C}=54.69$; $\text{H}=4.85$
 0.1030 „ 0.2039 CO_2 „ 0.0455 H_2O . $\text{C}=54.00$; $\text{H}=4.91$
 0.2542 „ 22.8 c.c. N_2 at 24.5° and 760 mm. $\text{N}=10.03$.
 0.2654 „ 0.1006 Sb_2O_3 . $\text{Sb}=29.93$.

$\text{C}_{18}\text{H}_{18}\text{N}_3\text{Sb}$ requires $\text{C}=54.54$; $\text{H}=4.54$; $\text{N}=10.6$;
 $\text{Sb}=30.30$ per cent.

Tri-*m*-aminotriphenylstibine is obtained in colourless crystals from glacial acetic acid only with considerable difficulty; it decomposes indefinitely at about 80°. The base dissolves sparingly in alcohol or water, and is but slightly soluble in acetone, benzene, and other volatile organic media.

The crystalline hydrochloride, $\text{Sb}(\text{C}_6\text{H}_4\cdot\text{NH}_2\cdot\text{HCl})_3$, is readily soluble in alcohol or water, but is precipitated from the latter by concentrated hydrochloric acid. Aqueous solutions of the salt are acid to litmus. The base and its salts, either in the solid state or in hot solutions, have a curious pungent odour, and cause violent fits of sneezing.

The hydrochloride was examined physiologically by Dr. Plimmer and by Mr. Hindle; it has a certain trypanocidal power, but nothing like so strong as lithium antimonyl tartrate, and its irritant effects are very acute, causing ulceration at the point of injection.

The base forms the following sparingly soluble salts: picrate, platinumchloride, and diazonium chloride; the last of these condenses with alkaline β -naphthol to form an insoluble, red azo-compound. The base itself in neutral or acetic acid solution couples with diazobenzene-sulphonic acid to produce a soluble azo-colouring matter.

Under the most favourable conditions the reduction of tri-*m*-nitrotriphenylstibinic acid does not proceed quite smoothly, being accompanied by elimination of antimony from combination with the organic groups. This destructive reduction becomes more pronounced when tin and hydrochloric acid are employed, and a considerable amount of aniline is produced. Tri-*m*-aminotriphenylstibine is not the sole product, as both reducing agents give rise to another basic substance which is soluble in alkali hydroxides as well as in acids; this product, which was not obtained crystalline and has no melting point below 230° , may possibly be tri-*m*-aminotriphenylstibine hydroxide.

The process employed by Michaelis and Reese (*loc. cit.*) for the preparation of diphenylstibine trichloride was adopted with slight modifications. Antimony trichloride (48 grams) and chlorobenzene (48 grams) dissolved in 150–200 c.c. of dry benzene were added in the cold to 20 grams of sodium which had been previously granulated by melting and shaking under boiling toluene. When a vigorous reaction did not take place spontaneously, it was started by cautiously warming the mixture. After twenty-four hours the solution was filtered from precipitated antimony and unaltered sodium; the benzene and toluene were evaporated away, the oily residue triturated with alcoholic hydrochloric acid till it solidified, and then dissolved in the minimum amount of boiling alcohol. The major portion of the triphenylstibine dichloride (m. p. 141°) crystallised out on cooling, and the mother liquor was concentrated until a second crop of crystals separated. This fraction, which consisted of impure diphenylstibine trichloride, was purified by extraction with hot dilute hydrochloric acid. The acid solution filtered from undissolved triphenylstibine dichloride deposited on cooling lustrous, colourless, lath-like crystals of diphenylstibine trichloride (m. p. 176°). This preparation was repeated several times, and the yields of diphenylstibine trichloride varied from 11 to 16 per cent. of the weight of antimony trichloride employed.

For purposes of nitration the trichloride was dissolved in alcohol, and converted, by means of silver nitrate, into a basic nitrate,

crystallising in clusters of lustrous, colourless needles, and decomposing at 206° with evolution of nitrous fumes.

Four grams of this basic nitrate were added to 56 c.c. of nitric acid (D 1.5) mixed with 20 c.c. of concentrated sulphuric acid; the temperature was maintained at 40°, and afterwards raised to 55°. The clear, yellow solution was then cooled, and poured out on ice; the pale yellow product was dissolved in *N*-sodium hydroxide and reprecipitated by acetic or hydrochloric acid:

0.2925 gave 18.0 c.c. N_2 at 29° and 768 mm. $N = 6.78$.

0.3248 „ 0.1254 Sb_2O_4 . $Sb = 30.48$.

$C_{12}H_9O_6N_2Sb$ requires $N = 7.05$; $Sb = 30.22$ per cent.

When crystallised from glacial acetic acid, *di-m-nitrodiphenylstibinic acid* separated in radiating clusters of flattened needles which decomposed somewhat indefinitely at 212°. The nitrate product before dissolving in aqueous alkali decomposes at 220° with evolving nitrous fumes; it probably consists, at least in part, of a nitrate or basic nitrate.

Di-m-nitrodiphenylstibinic acid is insoluble in water, alcohol, or benzene; its alkali salts are soluble in water to an orange-yellow solution; the other metallic salts obtained by double decomposition are very sparingly soluble.

Orientation Experiments.—Preliminary trials showed that *di-m-nitrodiphenylstibinic acid* was more stable than *tri-m-nitrotriphenylstibinic acid*. Sealed tubes containing the dinitro-acid, phosphorus pentabromide (2 mols.), and bromine (1 mol.) were heated at 100, 125°, and 130–160°. At the two lower temperatures no change occurred, but after heating for eight to nine hours at the higher temperature the organic antimony compound was decomposed, and on distilling in steam the product yielded 1-bromo-3-nitrobenzene (m. p. 56°). The residue consisted of antimony oxybromide and a small amount of viscid decomposition product.

The experiment at 130–160° was repeated with phosphorus pentabromide alone with a similar result; the volatile product was 1-bromo-3-nitrobenzene, and rather more tar was left in the residue.

Phenylstibine dichloride, the starting point in the preparation of monophenylated antimony compounds, was first prepared by Hasenbäumer (*loc. cit.*), and considerable quantities of this material were obtained by his process, which, however, was found to give diphenylstibine chloride as a by-product (Michaelis and Günther, *loc. cit.*).

A series of sealed tubes each containing 5 grams of triphenylstibine, 5.5 grams of dry antimony trichloride, and 12 c.c. of xylene dried over sodium was heated for forty-eight hours at 240° ; the liquid contents of the tubes were filtered from a black, insoluble impurity, shaken three times with dilute hydrochloric acid, dried over calcium chloride, and distilled up to 200° under the ordinary pressure. The oily residue was then fractionated under considerably diminished pressure (about 5–7 mm.), when about three-fourths of the material distilled between 160° and 200° , and the remainder was collected between 200° and 240° . Twenty-four grams of triphenylstibine yielded an equal weight of the lower, and about 6–7 grams of the higher, fraction; the latter, which consisted mainly of diphenylstibine chloride, soon solidified, and the crystals then melted at 60° , the melting point being raised to 65 after draining. The more volatile fraction, which consisted mainly of phenylstibine dichloride mixed with a smaller proportion of diphenylstibine chloride, either remained viscid or deposited crystals of the main constituent, which after draining melted at $15-58^{\circ}$.

Each of the foregoing fractions was suspended in dry cooled ether and treated with chlorine. In both cases the solution deposited colourless crystals, but whereas the crystals from the lower fraction melted at the ordinary temperature to a viscid oil, those from the higher fraction remained solid, and after crystallisation from dilute hydrochloric acid melted at 176° , and were thus identified as diphenylstibine trichloride.

The oily chlorine additive compound, consisting of impure phenylstibine tetrachloride, was hydrolysed with aqueous ammonia, when a solid residue was produced and identified as diphenylstibinic acid by conversion into diphenylstibine trichloride (m. p. 176°) by dissolving in hot alcoholic hydrochloric acid. The ammoniacal solution, which contained the greater part of the product of hydrolysis, was acidified with hydrochloric acid, when phenylstibinic acid was precipitated.

The solid chlorine additive compound was also hydrolysed by prolonged digestion with aqueous ammonia, when the greater part of the material remained undissolved, and was identified as diphenylstibinic acid. The ammoniacal filtrate when neutralised yielded a small quantity of phenylstibinic acid.

The Behaviour of Diphenylstibinic Acid towards Aqueous Alkalis.—Inasmuch as phenylstibinic acid is soluble in ammonia or aqueous sodium carbonate as well as in sodium hydroxide solution, and diphenylstibinic acid is described as being soluble in aqueous sodium hydroxide, but not in ammonia or sodium carbonate

* solutions, these differences might serve to effect the separation of the two acids in the mixtures obtained in the foregoing experiments. However, the behaviour of diphenylstibinic acid is so invariable in this respect, and its solubility in alkalis depends on the mode of formation.

Diphenylstibine trichloride was dissolved in alcohol and treated with dilute ammonia, when a granular precipitate was obtained insoluble in aqueous ammonia or sodium carbonate. Another portion of this trichloride was dissolved in aqueous sodium hydroxide, and the solution acidified with acetic acid; the diphenylstibinic acid thus precipitated is readily soluble in aqueous ammonia or sodium carbonate.

These two preparations are in all probability differently hydrated modifications of diphenylstibinic acid, the less soluble form being possibly the meta-compound, $\text{Ph}_2\text{SbO}\cdot\text{OH}$, whilst the more soluble product may be either the ortho- or pyro-compound.

Nitration of Phenylstibinic Acid.—Three grams of this acid were nitrated in 27 c.c. of pure nitric acid ($D=1.5$) and 9 c.c. of concentrated sulphuric acid, the temperature ranging from 40° to 50° . The cooled solution when poured on to ice gave a yellow precipitate which probably consists in part of a nitrate or basic nitrate, and on heating it decomposes with the evolution of nitrous fumes. The product was dissolved in dilute aqueous sodium hydroxide, and *m*-nitrophenylstibinic acid precipitated as a pale yellow compound on acidifying with acetic or hydrochloric acid. The acid dissolves in glacial acetic acid, but does not crystallise at all readily; it has no melting point below 290° :

0.3232 gave 13.7 c.c. N_2 at 27° and 760 mm. $N=4.68$.

0.3814 „ 0.1976 Sb_2O_3 . $\text{Sb}=40.91$.

$\text{C}_6\text{H}_5\text{O}_5\text{NSb}$ requires $N=4.79$; $\text{Sb}=41.10$ per cent.

Orientation Experiments.—One gram of *m*-nitrophenylstibinic acid, suspended in 15 c.c. of chloroform with 6 grams of phosphorus pentabromide, was heated at 100 – 110° for four hours, and the product then distilled in steam; 1-bromo-3-nitrobenzene was obtained, the yield being about 70 per cent. of the calculated amount. The residue contained a small quantity of tar.

Triphenylstibinedihydroxidetrissulphonic Acid.

The sulphonation of triphenylstibine dihydroxide proceeds so smoothly (than that of the previously described triphenylstibine hydroxysulphate (*Trans.*, 1910, **97**, 37), and accordingly the latter compound was generally employed for this purpose. Triphenylstibine dichloride sulphonates, evolving hydrogen chloride, but the

use of this dichloride offers no advantages. May's experiments (Trans., 1919, 97, 1958) show that the sulphonation of triphenylstibine itself is not a practicable operation, since the base acts as a reducing agent towards concentrated sulphuric acid, and becomes converted into triphenylstibineoxide sulphate.

Eight grams of the hydroxysulphate mixed with 20 c.c. of concentrated sulphuric acid were treated with 20 c.c. of fuming sulphuric acid (25 per cent. SO_3), the mixture heated at 100° for 20 to three hours, after which another 20 c.c. of fuming acid were added. The solution was left for twelve hours, poured on to ice, and the liquid neutralised with barium carbonate. The filtrate, freed from barium by the cautious addition of dilute sulphuric acid, was concentrated until of oily consistence, when alcohol produced a white precipitate. The filtrate was further concentrated, and treated repeatedly with alcohol and ether until a white deposit was no longer obtained. The final filtrate on evaporation left a clear, yellow oil, which was washed repeatedly with ether and dried over phosphoric oxide in a vacuum desiccator. Finally, a brittle, yellow mass was obtained resembling amber, the yield being about 40 per cent. of the weight of hydroxysulphate:

0.1806 gave 0.2068 CO_2 and 0.0600 H_2O . $\text{C}=31.23$; $\text{H}=3.69$.

0.4392 .. 0.5128 CO_2 .. 0.1112 H_2O . $\text{C}=31.84$; $\text{H}=2.81$.

0.1864 .. 0.0478 Sb_2S_3 . $\text{Sb}=18.32$.

$\text{C}_6\text{H}_5\text{O}_3\text{Sb}$ requires $\text{C}=31.80$; $\text{H}=3.3$; $\text{Sb}=17.67$ per cent.

These numbers agree with the formula:

the values for sulphur (16.0) were less concordant (theory=14.14 per cent.), showing that the compound still contains a small amount of more highly sulphonated organic compounds, but owing to the very soluble hygroscopic nature of the acid further purification could not be effected.

When titrated with standard sodium hydroxide and phenolphthalein, the compound was found to have a molecular weight of 567, on the assumption that it is a tribasic acid, the molecular weight calculated from the above formula being 679.

The metallic salts of triphenylstibinedihydroxidetrissulphonic acid are soluble in water; the sodium salt when triturated successively with phosphorus pentachloride and water yields a hydroxy-chloride, $\text{C}_6\text{H}_4(\text{SO}_2\text{Cl})_3\text{SbCl}\cdot\text{OH}$, which dissolves in benzene, and is precipitated therefrom by light petroleum as a granular powder, decomposing indefinitely at 110° :

0.1280 gave 0.1072 AgCl . $\text{Cl}=20.72$.

$\text{C}_{15}\text{H}_9\text{O}_7\text{Cl}_4\text{Sb}$ requires $\text{Cl}=20.32$ per cent.

The white substances precipitated by alcohol or by a mixture of this solvent and ether during the evaporation of solutions of the foregoing trisulphonic acid were found to be mixtures produced by the condensation of antimononic acid and benzenesulphonic and disulphonic acids, their formation being the sequel to the destructive action of concentrated sulphuric acid on the organic antimony compound.

One of these products was prepared synthetically by heating together an aqueous suspension of antimononic acid and benzenesulphonyl chloride. The latter compound underwent hydrolysis, the antimononic and benzenesulphonic acids condensed to form a soluble compound, which was deposited as a white, microcrystalline precipitate on adding alcohol to the concentrated aqueous solution. This compound, which may be regarded as a complex anhydride of the two acids, is readily soluble in water to a faintly acid solution, and contains about 29 per cent. of antimony and 18 per cent. of sulphur.

Physiological experiments by Dr. Plimmer showed that even the fatal doses triphenylstibinedihydroxidetrakisulphonic acid and the above-mentioned benzenesulphonylantimononic acid derivatives do not act as effective trypanocides.

We desire to express our thanks to Mr. G. S. Whitty, B.Sc., A.R.C.S., who collaborated in the earlier experiments, and to the Government Grant Committee of the Royal Society for a grant which has partly defrayed the expenses of this investigation.

CCLIII.—*The Preparation of the Ketones of the Higher Fatty Acids.*

By THOMAS HILL EASTERFIELD and CLARA MILLICENT TAYLOR
(New Zealand Government Research Scholar).

THE distillation of barium and calcium salts, although of general application as a method for obtaining ketones, suffers from the drawbacks that large quantities of salt cannot be conveniently treated in one operation, and that the yield of ketone is often unsatisfactory. Kraft (*Ber.*, 1882, 15, 1712) has shown that with fatty acids of high molecular weight the yield is improved by

heating the salts under diminished pressure, and Young (*Trans.*, 1891, **59**, 621) obtained no less than 80 per cent. of the theoretical yield of the ketone of phenylacetic acid by controlling the temperature at which the calcium salt was decomposed, and ensuring the rapid removal of the volatile products of the reaction. Kipping (*Trans.*, 1890, **57**, 532) obtained a 40 per cent. yield of stearone by heating stearic acid with phosphoric oxide. This very convenient method is, however, inapplicable to the higher unsaturated fatty acids. The observation (Easterfield and Bagley, *Trans.*, 1904, **85**, 1244) that in the presence of iron filings abietic acid is readily deprived of its carboxyl group with formation of a hydrocarbon suggested that iron filings might determine the formation of ketones from fatty acids at comparatively low temperatures. This is actually the case with the acids from lauric to melissic acid; thus stearic acid gave an 80 per cent. yield of stearone when heated with powdered cast-iron turnings to 360—370° for a period of three hours.

The hitherto undescribed ketones of the higher fatty acids can be prepared by the same process, but owing to decomposition the yield is not so good.

There can be little doubt that a ferrous salt is first formed, and that this then undergoes decomposition. Ferrous stearate heated to 360° slowly decomposes, and yields about 60 per cent. of stearone.

No satisfactory yield of ketone was obtained by the interaction of iron turnings and acetic, butyric, phenylacetic, benzoic, suberic, and sebacic acids, or with the acid ester of sebacic acid.

The observation that ketones may result by the interaction of acids and metals was first made by Liebig and Pelouze, who obtained acetone by passing the vapour of acetic acid through a heated iron tube, but obtained negative results when a porcelain tube was employed. Jahn (*Ber.*, 1880, **13**, 2107) obtained acetone and impure butyrene respectively by passing the vapours of the corresponding acids over heated zinc dust. Hébert (*Compt. rend.*, 1903, **136**, 682) obtained a mixture of stearone with solid and liquid hydrocarbons by distilling stearic acid with magnesium powder at as low a temperature as possible. Finally, Mailhe (*Bull. Soc. chim.*, 1909, [iv], **5**, 615) found that ketones are the chief products of the interaction of the vapours of the lower fatty acids, from acetic to benzoic acid, with many reduced metals, including such feebly electropositive metals as lead and copper, which in the form of ordinary filings are almost without action on the fatty acids.

The formation of stearone by the action of iron on stearic acid probably accounts for the fact recorded by P. W. Robertson (*Trans. N. Z. Inst.*, 1904, 576) that the last runnings in the commercial

distillation of stearin are so rich in stearone that the melting points of successive portions of the distillate fall rapidly to a eutectic and then rise with even greater rapidity. Examination of the higher distillates obtained in the refining of "distillation base" shows that they similarly contain oleone.

EXPERIMENTAL.

Preparation of Stearone.—Pure stearic acid was heated with one-tenth of its weight of sifted, clean cast-iron turnings to a temperature at which the evolution of carbon dioxide became perceptible. The temperature was then raised slowly to 360° and maintained between 360° and 370° for two hours. After removing the iron and free acid, the ketone was twice crystallized from petroleum (b. p. 100–120°), with the addition of animal charcoal, and it then melted at 83°. (Found, C=82.71; H=14.61. Calcd., C=83.00; H=13.83 per cent.) The yield of crude stearone melting at 85° was 80 per cent. of that demanded by theory.

In dealing with large quantities of stearic acid it is advised to raise the temperature rapidly to about 300°, and then to be very cautious about the further rise of temperature, as a sudden frothing sometimes commences at 320–330°.

The following table shows the comparative yields of stearone in a series of experiments made with the object of ascertaining the most suitable conditions of reaction. Column 1 gives the quantity of iron employed, expressed in terms of that theoretically required for the conversion of the whole of the acid into ferrous stearate. Columns 2, 3, and 4 give the percentage of the theoretical yield of ketone formed at the temperature indicated.

Percentage of iron.	Yield at 330°.	Yield at 360°.	Yield at 365°.
100	53	62	80
66	35	53	74
33	3	34	—
20	—	28	—

Unaltered iron remained in the experiments in column 4, an increase in the relative quantity of iron beyond the theoretical quantity did not improve the yield of ketone.

The experiments were carried out as follows: Test-tubes containing 1 gram of stearic acid and the requisite quantity of powdered cast-iron turnings were heated in a Lothar Meyer air-bath for three hours, the last 50° rise of temperature being allowed to occur one hour, at the end of which time the evolution of carbon dioxide had practically ceased. The product was treated with acid and alkali, and then once crystallized from alcohol, weighed, and the

melting point taken. In no case did the melting point differ by more than 4° from that required for the pure ketone. Very little ketone is formed if stearic acid or calcium stearate is heated to 300° or if stearic acid is heated with metallic iron at temperatures below 300° .

A sample of ferrous stearate prepared by adding ferrous acetate solution to an alcoholic solution of sodium acetate gave on analysis: Fe 8.9. Calc., Fe=9.0 per cent. This was heated to 360° for three hours, and the mass extracted with boiling alcohol; a 60 per cent. yield of stearone was obtained. Manganese stearate under similar conditions yielded 42 per cent. of ketone.

Good yields, up to 65 per cent., have been obtained by substituting aluminium and manganese for iron in the above operation.

Diheptadecylcarbinol, $(C_{17}H_{35})_2CH\cdot OH$.

The attempt to reduce stearone by means of ethyl alcohol and a very large excess of metallic sodium was unsuccessful, practically the whole of the ketone being recovered unchanged. Even with sodium and boiling amyl alcohol the reduction takes place but slowly.

One gram of stearone was dissolved in 200 c.c. of boiling amyl alcohol, and 8 grams of sodium were added in small portions at a time during a period of eight hours. The carbinol which crystallised out on cooling was recrystallised from amyl alcohol, and melted at 89.5° . It is much more soluble in ethyl alcohol than the ketone from which it is prepared.

The acetate prepared from the carbinol melted at $54-61^{\circ}$. Lack of sharpness in the melting point was observed by Kipping (*Trans.*, 190, 57, 987) in the case of dipentadecylcarbinyl acetate prepared from palmitone, and the same phenomenon is noticed in the acetates of the carbinols obtained from cerotone and montanone:

0.1240 gave 0.3674 CO_2 and 0.1517 H_2O . C=80.80; H=13.54.

$C_{32}H_{74}O_2$ requires C=80.73; H=13.45 per cent.

Cerotone, $C_{31}H_{102}O$.

According to Beilstein (Vol. I, p. 1006), cerotone was obtained by Brückner by the distillation of lead cerotate, and melted at 12° , but the ketone prepared by Nafziger on distillation of the ceric acid melted at 92° . Mr. T. Rigg, M.Sc., kindly undertook the investigation of the action of iron turnings on cerotic acid, and supplies the following note.

The cerotic acid was prepared from beeswax by combining the methods of Brodie and of Marie, and melted at 77.5° (uncorr.).

Nine grams of the acid were heated with 0.69 gram of sifted cast-iron turnings, the temperature being allowed to rise to 320° , at which temperature the mixture was maintained for four hours. Evolution of carbon dioxide began at about 280° . After removal of iron and unchanged cerotic acid, the product of the reaction was recrystallised from light petroleum (b. p. $80-100^{\circ}$) until the melting point was constant. The yield was 55 per cent.; in a second experiment, in which the temperature was maintained at 360° for three hours, a 70 per cent. yield was obtained.

Cerotone prepared in this way melts at 93° ; it is moderately soluble in light petroleum or ethyl acetate. It separates from hot glacial acetic acid in feathery groups of crystals. In hot ethyl alcohol it is almost insoluble, the solution merely becoming slightly turbid on cooling. (Found, C=83.50; H=13.93. Calc., C=83.50; H=13.97 per cent.)

Dipentacosylcarbinol, $(C_{25}H_{51})_2CH\cdot OH$, prepared by reducing cerotone with sodium in boiling amyl alcoholic solution, melted at 95° . The acetate prepared from this alcohol melted at $58-60^{\circ}$.

0.1068 gave 0.3207 CO_2 and 0.1315 H_2O . C=81.89; H=13.67.
 $C_{53}H_{106}O_2$ requires C=82.17; H=13.69 per cent.

Cerotoxime, $(C_{25}H_{49})_2C\cdot NOH$, was prepared by boiling 1 gram of cerotone dissolved in 150 c.c. of amyl alcohol with 2 grams of hydroxylamine hydrochloride and excess of potassium hydroxide. It was crystallised from ethyl acetate, and melted at 78° :

0.1227 gave 0.3696 CO_2 and 0.1505 H_2O . C=82.15; H=13.61.
 0.44 " NH_3 equivalent to 4.95 c.c. $N/10\text{-HCl}$. N=1.58
 $C_{51}H_{103}ON$ requires C=82.14; H=13.82; N=1.87 per cent.

Montanone, $(C_{27}H_{55})_2CO$.

Montanic acid, prepared from Montan wax, was recrystallised from alcohol, and finally from glacial acetic acid until the melting point was constant at 82.5° (uncorr.). The titration value of the acid agreed sharply with that required for an acid of the formula $C_{26}H_{56}O_2$, as stated by Ryan and Dillon (*Sci. Proc. Roy. Dubl. Soc.*, 1909, **12**, 202), not with $C_{29}H_{58}O_2$, as given by Heide (*Zeitsch. angew. Chem.*, 1900, **14**, 556) and by Eisenreich (*Chem. Rev. Fett. Harz-Ind.*, 1909, **16**, 211).

The ketone was prepared as in the case of stearone, a 50 per cent. yield being obtained. It melts at 97° , and is conveniently recrystallised from glacial acetic acid:

0.1124 gave 0.3456 CO_2 and 0.1415 H_2O . C=83.85; H=13.98
 $C_{53}H_{104}O$ requires C=83.96; H=13.97 per cent.

Montanonecerime melts at 82.5° , and is very sparingly soluble in alcohol, more readily so in ethyl acetate:

0.571 gave NH_3 equal to 4.2 c.c. $\text{N}/10\text{-HCl}$. $\text{N}=1.74$.

$\text{C}_{33}\text{H}_{51}\text{ON}$ requires $\text{N}=1.72$ per cent.

The *ketone* obtained by reduction of montanone melts at 101° ; the corresponding *acetate* melts at 66° .

Melissone.

The melissic acid was prepared from New Zealand beeswax, and was separated from the cerotic acid by means of the very sparing solubility of sodium melissate in hot 95 per cent. alcohol, in which 95 per cent. sodium cerotate is rather easily soluble. The acid melted at 55.5° (uncorr.).

The ketone was prepared by heating the acid with metallic iron for two hours at 370° ; the yield was 47 per cent. of that demanded by theory.

Melissone melts at 99.5° , is practically insoluble in boiling absolute alcohol, but may be conveniently recrystallised from amyl alcohol or glacial acetic acid:

0.504 gave 0.2489 CO_2 and 0.1018 H_2O . $\text{C}=84.32$; $\text{H}=14.06$.

$\text{C}_{29}\text{H}_{48}\text{O}$ requires $\text{C}=84.08$; $\text{H}=14.01$ per cent.

Schwalbe (*Diag.*, Tübingen) observed a ketone melting at $97-99^{\circ}$ amongst the products of the soda-lime fusion of myricyl alcohol from beeswax.

Melissontotime melts at 84° .

Oleone, $\text{C}_{35}\text{H}_{66}\text{O}$.

According to Beilstein (Vol. I., p. 1006) no ketones have hitherto been prepared from the unsaturated acids, $\text{C}_n\text{H}_{2n-2}\text{O}_2$. In Watt's Dictionary (Vol. IV., pp. 193 and 196) it is stated that Bussy obtained a neutral, oily liquid by distilling oleic acid with lime, and that he regarded this as oleone. Attempts to prepare oleone by the interaction of oleic acid and phosphoric oxide were unsuccessful, a viscid tar resulting, from which no definite compounds could be extracted by organic solvents. Oleone can, however, be isolated from the distillation products of barium oleate, and more readily from the reaction product of iron with oleic acid. It is also present in the fractions of highest boiling point of commercial oleic acid.

1. Forty grams of barium oleate (Found, $\text{Ba}=19.4$. Calc., $\text{Ba}=19.6$ per cent.), recrystallised from a mixture of benzene and alcohol (Farnsteiner, *Zeitsch. Nahr. Genussm.*, 1899, 2, 1), were

heated in a flask immersed in a bath of molten solder. A current of hydrogen was passed into the flask throughout the operation, and the pressure was kept below 100 mm. A device similar to that used by Yonge (Trans., 1891, 59, 623) was employed to remove the volatile products as rapidly as possible. A distillate first appeared at $280^{\circ}/25$ mm., and was pale yellow and viscous. As the temperature rose, the distillate became darker and more viscous, and the pressure in the apparatus rose. Distillation ceased and the pressure again fell before a temperature of 330° was attained. The total distillate was a reddish-brown, viscous liquid showing a green fluorescence. A small quantity of crystals separated on keeping, and a further crop was obtained by fractionating the crude distillate under diminished pressure and collecting the fraction distilling between 280° and $330^{\circ}/5-10$ mm. The weight of crystals was only 2 per cent. of that demanded by the theory for the production of oleone from the barium salt.

After repeated crystallisation from alcohol the substance melted at 59° :

0.1062 gave 0.3252 CO_2 and 0.1260 H_2O . $\text{C}=83.3$; $\text{H}=13.1$.

By ebullioscopic method in alcohol: Found, $\text{M.W.}=492$ and 502 . $\text{C}_{35}\text{H}_{60}\text{O}$ requires $\text{C}=83.66$; $\text{H}=13.14$ per cent. $\text{M.W.}=502$.

The bromine absorption in chloroform solution after twelve hours was 62.1 per cent. The absorption of four atoms of bromine requires 63.8 per cent.

It is, of course, possible that in the formation of this oleone the position of the ethylene linkings may have changed from the positions occupied in the oleic acid.

It is not a little remarkable that the distillate boiling at $280-330^{\circ}$, from which the oleone crystals have been removed as far as possible by cooling and filtration, still has almost the same composition as the crystals themselves. (Found, $\text{C}=83$, $\text{H}=13.0$.) This calls to mind an observation by Miller and Tschitschkin (*Annalen*, 1899, 307, 375) that the distillate from the calcium salt of azelaic acid yields a fraction boiling at $180-200^{\circ}$, the analysis of which agrees with that required for cyclooctanone, but the existence of this compound could only be proved in the fractions boiling above 200° .

II. *Preparation of Oleone by the Interaction of Iron and Oleic Acid*.—One gram of oleic acid prepared from the commercial acid by repeated rectification in a vacuum and removal of saturated fatty acids by freezing, and 5 grams of practically pure oleic acid (prepared from olivo oil, solidifying completely at 14° , and yielding a lead salt completely soluble in ether) were separately heated with one-tenth of their weights of powdered and sifted cast-iron turnings

Reduction of carbon dioxide began at 240° . The mixture was slowly heated to 340° , and this temperature maintained for two hours, much frothing occurred towards the end of the reaction. After removal of iron and acidic substances, the semi-solid product was crystallised several times from alcohol and acetic acid until the melting point was constant at 59.5° . The yield in each case was 50 per cent. of the oleic acid taken:

0.1089 gave 0.3335 CO_2 and 0.1332 H_2O . $\text{C} = 83.5$; $\text{H} = 13.6$.

$\text{C}_{26}\text{H}_{50}\text{O}$ requires $\text{C} = 83.6$; $\text{H} = 13.1$ per cent.

From oleic acid heated to 340° for two hours in the absence of iron no oleone could be isolated.

(H) *Isolation of Oleone from Commercial Oleic Acid*.—Since commercial olein is prepared by the steam distillation of crude stearin from cast-iron retorts, the temperature in which frequently exceeds 300° , the presence of oleone is to be expected in commercial oleic acid. By the kindness of the directors and manager (Mr. Bull) of the New Zealand Candle Co. we have been supplied with samples taken during the redistillation of 2 tons of commercial olein, an operation extending over five hours.

The fractions collected during the first four hours distilled almost completely below $270^{\circ}/50$ mm. The portions passing over during the last fifteen minutes were filtered from solids, and only began to boil at $270^{\circ}/50$ mm.; a large portion boiled above $300^{\circ}/25$ mm.

Oleone was obtained from these higher fractions by dissolving in a large volume of alcohol and neutralising with sodium hydroxide, which caused the separation of an oil insoluble in the soap solution. This oil on keeping deposited crystals, which melted at 59° after repeated crystallisation from alcohol and acetic acid.

When prepared by any of these methods *oleone* is a colourless substance, crystallising from alcohol or acetic acid in hair-like needles. It is sparingly soluble, even in boiling alcohol, more readily so in ether, ethyl acetate, glacial acetic acid, or chloroform.

Oleoneoxime melts at 31° , and is readily soluble in alcohol:

0.1334 gave 2.9 c.c. N_2 at N.T.P. $\text{N} = 2.73$.

$\text{C}_{26}\text{H}_{47}\text{ON}$ requires $\text{N} = 2.70$ per cent.

Reduction of Oleone to Pentatriacontane.—0.5 Gram of oleone was warmed with phosphorus pentachloride, and the product subsequently reduced with hydriodic acid and phosphorus at 240° . The resulting hydrocarbon was recrystallised from ether, and melted at 73° . (Found, $\text{C} = 85.8$; $\text{H} = 14.8$. Calc., $\text{C} = 85.3$; $\text{H} = 14.6$ per cent.) Pentatriacontane melts at 74.7° (Krafft, *Ber.*, 1882, 15, 1715).

Elaidone.

Two grams of pure elaidic acid were heated with iron under similar conditions to those employed for the preparation of oleone. The elaidone was recrystallised from alcohol, and melted at 13°. The yield was only 15 per cent. when the maximum temperature employed was 320°; a larger yield was obtained in an experiment in which the maximum temperature was 350°, but the ketone produced at the higher temperature was not readily brought to a sharp melting point by recrystallisation:

Found: C=83.33; H=13.27.

$C_{35}H_{66}O$ requires C=83.62; H=13.14 per cent.

Elaidoneoxime crystallises from alcohol in long needles, which melt at 32°; it is more readily soluble than the oxime of oleone.

0.3678 gave NH_3 equal to 7.8 c.c. $N/10-HCl$. N=2.96.

$C_{35}H_{67}ON$ requires N=2.71 per cent.

Brassidone.

This was prepared from brassidic acid and metallic iron, and melts at 80°. The yield at 280° was 20 per cent., at 320° 50 per cent., of the acid employed. The compound is readily soluble in hot alcohol:

0.1237 gave 0.3787 CO_2 and 0.1495 H_2O . C=83.42; H=13.4.

$C_{43}H_{89}O$ requires C=84.03; H=13.33 per cent.

Brassidoneoxime melts at 51°:

0.3078 gave NH_3 equal to 4.6 c.c. $N/10-HCl$. N=2.19.

$C_{43}H_{83}ON$ requires N=2.22 per cent.

Action of Iron on Erucic Acid.

Carefully purified erucic acid was heated with powdered iron turnings for three hours at 300–320°. The resulting neutral compound, even after repeated recrystallisation from a variety of solvents, melted at 50–60°, although the analytical numbers agreed with those required for erucicone. (Found, C=83.88; H=13.4. $C_{43}H_{89}O$ requires C=84.04; H=13.33 per cent.) From the products of distillation of barium erucate under diminished pressure a similar product of indefinite melting point was obtained.

The result would be readily explained if, during the process of heating, a portion of the erucic acid were changed into any of the numerous possible isomerides, so that the ultimate product would be a mixture of isomeric ketones.

Some support in favour of this view is given by the observation

that a sample of the same erucic acid when heated alone for two hours at 280–300° yielded a small quantity of an acid melting at about 50°. The original erucic acid melted at 34°.

The expenses of this investigation have been defrayed by a grant from the Research Scholarship Fund of the Government of New Zealand.

CCLIV.—*The Separation of Mixtures of Organic Acids by Partial Esterification.*

By JOHN JOSEPH SUDBOROUGH and EBENEZER REES THOMAS.

THE difference between the esterification constant of an $\alpha\beta$ -unsaturated acid and its saturated analogue, and between the constants for corresponding $\alpha\beta$ - and $\beta\gamma$ -acids, and also $\alpha\beta$ - and $\gamma\delta$ -acids (Trans., 1905, **67**, 1840; 1907, **91**, 1033; 1909, **95**, 315, 975), suggested that possibly mixtures of those acids might be separated by partial esterification. It was found that under specific conditions a separation is brought about by one treatment with alcohol and hydrogen chloride, that the method is perfectly general, and that it can be used whether the composition of the mixture is known or not.

For any such mixture of acids the following general method may be used. The mixture is treated with 0.22*N*-ethyl-alcoholic hydrogen chloride, when the more readily esterified acid has E'_{HClOH} about 40. When it is less, the strength of the hydrogen chloride must be rather more than $0.22 \times 40 \times N/E'$ (where E' is the esterification constant of the more readily esterified acid in the mixture). About twenty-five to thirty times the amount of alcohol required to combine with the weight of the more readily esterified acid present must be taken. When the composition of the mixture is unknown, it may be regarded as all more readily esterifiable acid. The solution is left at about 20° for five hours or longer,* and then poured into

* With acids of E'_{HClOH} about 50 a shorter time will suffice. In all cases if left considerably longer than the exact time required, very little difference will be made. In one experiment where four and a half hours would have been a suitable period, the mixture was left for seventeen and a-half hours and a good separation was obtained (Expt. 1).

about four times its volume of water; the liquid is made alkaline with sodium carbonate, the ester extracted with ether, the extract washed, dried, and distilled, and the ester hydrolysed. The acid may be obtained either by acidifying the alkaline liquid and extracting with ether, or, where insoluble in water, by precipitation. In some cases it may be convenient to obtain the greater part by precipitation, the remainder being extracted from the filtrate with ether.

In working out the conditions, preliminary experiments were carried out, 1 c.c. of the solution being titrated from time to time with standard alkali. Where the $E_{\text{NaOH}}^{1\%}$ of the acids present in the mixture is unknown, the conditions may be found in this way.

The method has been used for:

A. Separation of $\alpha\beta$ -Unsaturated Acids from their Saturated Analogues.

- i. *Cinnamic and β -Phenylpropionic Acids* (compare experiments 1—6).—The method is of interest in this case in view of the fact that in the preparation of β -phenylpropionic acid by the reduction of cinnamic acid, the reduction is seldom complete, and the resulting product is somewhat difficult to purify by recrystallisation.
- ii. *Crotonic and Butyric Acids* (compare experiments 7 and 8).
- iii. *Dimethylacrylic and isoValeric Acids* (compare experiments 9 and 10).

B. Separation of Mixtures of $\alpha\beta$ - and $\beta\gamma$ -Unsaturated Acids

The method is of interest in two special cases:

- i. Where, as in the case of β -ethylacrylic and ethylidenepropionic acids, a mixture of the acids is produced during their preparation. (For separation see experiments 13 and 14.)
- ii. When a mixture of the two acids is obtained by boiling the $\beta\gamma$ -acid for twenty to fifty hours with excess of sodium hydroxide (Fittig, *Annalen*, 1894, **283**, 51), for example, hydrosorbic and $\alpha\beta$ -hexenoic acids. (For separation see experiments 15 and 16.)

A mixture of cinnamic acid and phenylisocrotonic acid was also separated by this method (compare experiments 11 and 12).

The method at present in use for the separation of $\alpha\beta$ - and $\beta\gamma$ -unsaturated acids is that described by Fittig (*loc. cit.*). With this method (i) considerable difficulty is experienced in working it. Fittig states (*loc. cit.*), "dass sie in anderen Händen nicht immer zu so glatten Resultaten geführt hat." Several experiments on the purification of $\alpha\beta$ -pentenoic acid by Fittig's method were carried

put by the authors (Trans., 1907, 91, 1035), and in these cases very poor yields were obtained, although great care was taken as to conditions. The method here described presents none of these difficulties, and one esterification is sufficient to give a good separation, whilst three treatments with sulphuric acid are necessary in order to obtain the $\alpha\beta$ -acid pure.

(iii) All the $\beta\gamma$ -acid is lost in the form of the γ -lactone. In the case of hydrosorbic acid, the yield of crude $\alpha\beta$ -acid is never more than 30 per cent. of the weight of hydrosorbic acid used (*Annalen*, 1891, 283, 119), 70 per cent. being thus practically destroyed. In the partial esterification method the only appreciable loss is due to the inevitable formation of hydroxy-acid—about 25 per cent. of the weight of hydrosorbic acid used.

It has been shown by Fichter (*Ber.*, 1909, 42, 4707) that β -methyl- Δ^2 -pentenoic acid is quantitatively transformed into lactone under the conditions described by Fittig for the purification of $\alpha\beta$ -acids. They were therefore unable to determine whether β -methyl- Δ^2 -pentenoic acid was transformed into the Δ^2 -acid or not by boiling with sodium hydroxide solution. It is hoped that the method described in this paper may be of some use in deciding this point.

C. Separation of $\alpha\beta$ - and $\gamma\delta$ -Acids.

A mixture of δ -phenyl- Δ^2 - and Δ^2 -pentenoic acids was separated in this way (compare experiment 17).

EXPERIMENTAL.

Experiment 1.—Cinnamic and β -Phenylpropionic Acids (preliminary).—Two grams of cinnamic acid (recrystallised storax acid) and 25 grams of β -phenylpropionic acid (m. p. 47.5°) were dissolved in 15 c.c. of ethyl alcohol, and 5 c.c. of 0.8*N*-solution of hydrogen chloride in ethyl alcohol added, thus giving 20 c.c. of 0.22*N*-hydrogen chloride. In order to watch the course of the reaction, 1 c.c. was removed from time to time, and titrated with 0.0262*N*-barium hydroxide solution, of which by calculation hydrogen chloride required 8.5 c.c.; cinnamic acid, 25.5 c.c.; together 33.5 c.c.; β -phenylpropionic acid, 31 c.c.

After	0.3	0.5	1	1.5	2.5	4	17.5
l.c.c. required	50	48	43.7	40	36	33.7	28
							c.c.

From these results it was concluded that presumably nearly all the β -phenylpropionic acid was esterified at the end of about four hours under these conditions, whilst even after leaving for another thirteen hours, only a comparatively small quantity of the cinnamic

acid was esterified. To test this conclusion, the remainder of the alcoholic solution (which had been left for 17.5 hours) was poured into water, and treated as described in the introduction.

1.20 Grams of an acid, melting at about 131° , and 2.68 grams of an ester were obtained. The ester, when hydrolysed, yielded 1.64 grams of an acid melting at $45-47^{\circ}$.

Experiment 2.—Cinnamic and β -Phenylpropionic Acids.—A mixture of 10 grams of each acid was dissolved in 75 c.c. of ethyl alcohol, and 25 c.c. of 0.89*N*-hydrogen chloride in alcohol added. The mixture was left at 18° for about five hours, then poured into 400 c.c. of water, and treated as described in the introduction.

11.99 Grams of ester were obtained, and from the alkaline liquor after rendering acid and extracting with ether, 9.56 grams of cinnamic acid (m. p. $129.5-132^{\circ}$) were obtained.

The ester was distilled, and 11.20 grams, boiling at $244-246/772$ mm., were collected. This was hydrolysed by means of alcoholic solution, and the acid recovered as before.

8.96 Grams of β -phenylpropionic acid (m. p. $46-47.5^{\circ}$) were obtained. 5.72 Grams of this acid were pressed on filter-paper and then melted at $48-49^{\circ}$. The melting point given by Fick (Ber., 1890, 23, 148) is 48.7° . Hence 4.5 grams of this acid were recrystallised from light petroleum (b. p. $35-42^{\circ}$). Three fractions were obtained; (i) 2.73 grams, m. p. $48.5-49.5^{\circ}$; (ii) 1.0 gram, m. p. $48-49^{\circ}$; (iii) 0.76 gram, m. p. $47-48^{\circ}$.

An experiment was subsequently carried out with a mixture in equal proportions of these acids, the cinnamic acid being recovered by precipitation.

Experiment 3.—Five grams of each acid were dissolved in 100 c.c. of ethyl alcohol, 10 c.c. of 1.08*N*-hydrogen chloride in ethyl alcohol were added, and the solution left at 20° for six hours. The mixture was then poured into water, and the ester extracted as before. 5.57 grams of ester, boiling at $243-245^{\circ}/758$ mm., were obtained (=4.83 grams of acid).

The alkaline solution was carefully heated on the steam-bath so as to remove all the ether, cooled, and treated with concentrated hydrochloric acid in excess, when 4.73 grams of cinnamic acid (m. p. $129-131^{\circ}$) were obtained.

Experiments were then conducted to study the conditions for separation when the two acids are not present in equal proportions.

A. When β -Phenylpropionic Acid is in the Larger Proportion

Experiment 4.—Three grams of β -phenylpropionic acid and 1 gram of cinnamic acid were dissolved in 15 c.c. of alcohol. 5 c.c. of 0.89*N*-hydrogen chloride added, and 1 c.c. of the solution

titrated from time to time with 0.0262*N*-barium hydroxide solution, of which by calculation hydrogen chloride requires 8.5 c.c.; cinnamic acid, 12.75 c.c.; together 21.2 c.c.; β -phenylpropionic acid, 43.75 c.c.

	After	1	2	4	5.5 hours
	1 c.c. required	32.6	28.3	23.4	22.2 c.c.

The mixture was left for another hour (6.5 hours in all), and then poured into water and treated as before, giving 0.94 gram of cinnamic acid (m. p. 127—129°) and 2.55 grams of β -phenylpropionic acid, which, on pressing on filter-paper, lost a little oil and melted at 48.8—49.4°.

B. When Cinnamic Acid is in the Larger Proportion.

Experiment 5.—Three grams of cinnamic acid and 1 gram of β -phenylpropionic acid were dissolved in 15 c.c. of alcohol (solution warmed and cooled), and 5 c.c. of 0.89*N*-alcoholic hydrogen chloride added. One c.c. was removed and titrated as before with 0.0262*N*-barium hydroxide solution, of which hydrogen chloride required 8.5 c.c.; cinnamic acid, 38.0 c.c.; together 46.5 c.c.; β -phenylpropionic acid, 12.6 c.c. After one and 1.5 hours, 1 c.c. required 44.3 and 43.7 c.c. respectively.

At the end of 1.5 hours, the mixture was poured into water and treated as before, and 0.97 gram of ester and 2.72 grams of cinnamic acid (m. p. 126—128.5°) were obtained.

Experiment 6.—*Purification of crude β -phenylpropionic acid, which had been prepared by the reduction of cinnamic acid.*—The crude acid (10.2 grams, m. p. 41—45°) was shaken with alcohol (4 c.c.), and, after settling, the clear liquid was decanted. The flask was rinsed with 10 c.c. of alcohol, which was filtered and added to the solution (weight of insoluble residue 0.10 gram). 10*N*-Alcoholic hydrogen chloride (25 c.c.) was then added, and the mixture left at 20° for about nine hours. It was poured into water, and treated as before. The ester was distilled, and 10.2 grams of ester (b. p. 243—246°/758 mm.) were obtained (=8.5 grams of acid).

The acid impurity was precipitated from the solution of the sodium salt with hydrochloric acid, collected, washed with water, and dried, when 1.30 grams of cinnamic acid (m. p. 128.5—130°) were obtained.

Separation of Crotonic and Butyric Acid.

Crotonic acid ($E_{\text{NaOH}}^{25} = 1.28$), melting at 71—71.4°, and butyric acid ($E_{\text{NaOH}}^{25} = 41.63$), boiling at 164—165°, were used.

Experiment 7 (preliminary).—A mixture of 2 grams of crotonic acid was dissolved in 15 c.c. of alcohol, and 5 c.c. of 0.8*N*. valeric acid and hydrogen chloride were added. 1 C.c. of the mixture was titrated with 0.0262*N*-barium hydroxide solution, of which hydrogen chloride requires 8.5 c.c.; crotonic acid, 45.0 c.c.; together 53.5 c.c.; butyric acid, 44 c.c. After 1, 2, and 4.5 hours, 1 c.c. required 65, 60, and 51.6 c.c. respectively.

At the end of 4.5 hours the mixture was poured into water, and treated as before. 1.69 Grams of crotonic acid (m. p. 61°) were obtained. Owing to its extreme volatility, no constant amount of the ester could be observed. The conditions for the separation of these two acids are therefore exactly similar to those used for cinnamic and β -phenylpropionic acids, except that precautions must be taken to avoid loss of ester by volatilisation.

Experiment 8.—Ten grams of each acid were mixed and dissolved in 80 c.c. of alcohol, and 21 c.c. of 1.08*N*-alcoholic hydrogen chloride were added. The mixture was left at 18° for nearly four and a-half hours, poured into water, and neutralised as before. It was then extracted three times with ether, and the ethereal extract washed three times with one-third its volume of water and dried. The acid was obtained in a similar manner on acidifying with hydrochloric acid and extracting with ether.

To avoid loss of ethyl butyrate by volatilisation with the ether vapour, the residue was distilled very slowly from a small distillation flask with a comparatively long neck. A constriction was made at the lower end of the neck, which was filled with glass beads, and a tube for the introduction of more of the liquid passed through the beads and was closed by rubber and a pinchcock at the upper end. Ten grams of ethyl butyrate (b. p. 120–121–773 mm.) were obtained.

The crotonic acid was distilled and left in a desiccator. 2.5 Grams of acid, melting at about 61°, were obtained. 2.6 Grams were recrystallised from light petroleum (b. p. 40–60°), and gave 1 gram melting at 71–71.2°, 0.9 gram melting at 69.5–70°, and 0.45 gram melting at 67–69°.

Separation of Dimethylacrylic and isoValeric Acids

Dimethylacrylic acid ($E_{\text{D}}^{\text{W}} = 0.285$, m. p. 67.8–68°), prepared by Barbier and Leser's method (*Bull. Soc. chim.*, 1905, [iii], 33, 815) from mesityl oxide and sodium hypochlorite, and isovaleric acid ($E_{\text{D}}^{\text{W}} = 12.3$, b. p. 174.5–175.1°/740 mm.) were used in the experiment.

Experiment 9 (preliminary).—As the esterification constants of these acids are approximately one-quarter of those of cinnamic and

3-phenylpropionic acids, it was thought advisable to use alcoholic hydrogen chloride four times as strong as that used in the previous experiments, the rate of esterification being proportional to the strength of the hydrogen chloride. Hence a mixture of 2 grams of dimethylacrylic acid and 2.3 grams of isovaleric acid was dissolved in 19 c.c. of alcohol, and 15 c.c. of 1.46*N*-alcoholic hydrogen chloride were added. One c.c. of this solution was titrated against 0.01*N* barium hydroxide solution, of which hydrogen chloride required 28.2 c.c.; dimethylacrylic acid, 25.3 c.c.; together 53.5 c.c.; isovaleric acid, 29.1 c.c. After leaving for four and six and a-half hours, 1 c.c. required 57.1 and 53.7 c.c. respectively, thus under these conditions leaving for six and a-half hours will probably bring about a separation.

Experiment 10.—Ten grams of dimethylacrylic acid were dissolved on warming in 20 c.c. of alcohol. The solution was cooled, and 10 grams of isovaleric acid were added. To the solution 90 c.c. of 1.08*N*-alcoholic hydrogen chloride were added, and the mixture was left at 20° for six and a-half hours. It was then poured into water and treated as before. The ether was in this case also distilled off very carefully from the ester, and the following fractions were collected: Below 78°; 78—100°; and, of which 9.65 grams were obtained, 133—135°/737 mm. Ether was added to the fraction b. p. 78—100°, which was then treated twice with its own volume of water, the ethereal layer being separated and dried. The fraction b. p. 133—135°/740 mm., obtained on distillation, was added to the former amount of ester obtained; the total weight of pure ester was 11.23 grams. As dimethylacrylic acid is appreciably soluble in water, the solution of the sodium salt was evaporated to a small volume, cooled, and then acidified with hydrochloric acid. The weight of acid obtained was 6.10 grams (m. p. 67.3°), and from the aqueous filtrate was extracted, by means of ether, 3.45 grams, of which 2.12 grams were pressed on a porous plate, yielding 1.90 grams of acid melting at 69°.

Separation of Mixtures of αβ- and βγ-Unsaturated Acids.

Cinnamic Acid and Phenylisocrotonic Acid ($E_{\text{NaOH}}^{16} = 86.6$).—Recrystallised storax cinnamic acid and phenylisocrotonic acid (m. p. 86°), prepared from phenylparaconic acid (Trans., 1907, 91, 1034), were used.

Experiment 11.—A mixture of 2 grams of each acid was dissolved in 20 c.c. of warm alcohol, and the solution cooled; 5 c.c. of 1.08*N*-alcoholic hydrogen chloride were added, and 1 c.c. of the mixture titrated as before with 0.0262*N*-barium hydroxide

ance in addition to the two acids. It was purified as follows: The liquid was shaken with a solution of sodium carbonate, and extracted three times with ether, the ethereal solution finally yielding 3 grams of a neutral oil boiling at about 200° .

The alkaline solution was acidified with hydrochloric acid, and extracted with ether as before; 10.5 grams of a fraction boiling at $190-203^{\circ}$ were obtained:

0.0682 required 26.05 c.c. 0.0262*N*-barium hydroxide. Calc., 26.0 c.c.

Hence probably a mixture of β -ethylacrylic and ethylidenepropionic acids was present.

Separation of the Mixture.—Ten grams of the mixture were placed in a flask, and 60 c.c. of alcohol and 15 c.c. of 1.08*N*-alcoholic hydrogen chloride were added. The solution was left at 20° for four and a-half hours, and then poured into water and treated as before. The ether was very slowly distilled from the ethereal solution of the acid, using the glass beads, etc., described in experiment 8.

4.7 Grams of acid, boiling at about 200° , were obtained. Some ether was distilled off from the ethereal solution of the ester, and the remainder kept for treatment with that obtained in experiment 14.

Experiment 14.—The mixture of acids was prepared as before, 6 grams of a fraction boiling at $190-205^{\circ}$ being obtained. This was purified as described in experiment 13, and 9.3 grams of acid boiling at $190-203^{\circ}$ were obtained:

0.1496 required 55.5 c.c. 0.0262*N*-barium hydroxide. Calc., 57 c.c.
0.0932 " 34.3 c.c. " " Calc., 35.5 c.c.

The mixture therefore contained only 97 per cent. of the acids.

Separation of the Mixture.—Nine grams of the mixture were mixed with 60 c.c. of alcohol, 17 c.c. of 1.08*N*-alcoholic hydrogen chloride added, and the solution left at 20° for four and a-half hours. It was then poured into water, and treated exactly as in experiment 13. 4.35 Grams of acid, boiling at $198-201^{\circ}/37$ mm. were obtained, and this was added to the 4.7 grams obtained in experiment 13. The mixture, on distillation, gave 13 grams of ethylacrylic acid (b. p. $197-201^{\circ}/751$ mm.). This was placed in a freezing mixture, when the greater part solidified, melting at 5° (Fittig and Mackenzie, *Annalen*, 1894, 283, 83, give -10.5° as the melting point of the pure acid).

The ethereal solution of the ester was mixed with that obtained in experiment 13, and the ether slowly distilled, using a rod-and-bk fractionating column. When nearly all the ether had been

removed, the ester was hydrolysed by means of barium hydroxide solution, and the crystalline barium ethylidenepropionate obtained and weighed.

Four hundred c.c. of barium hydroxide solution (saturated at 15°) were added to the ester, and the whole was boiled in a reflux apparatus for two hours, when apparently complete hydrolysis had taken place. The liquid was extracted once with ether to remove any unhydrolysed ester, and then freed from ether by passing steam through it. Carefully washed carbon dioxide was then passed through the hot solution to precipitate any excess of barium hydroxide, and the solution filtered. On evaporating to a small volume, cooling, and adding alcohol, pearly-white crystals were precipitated. These were removed, washed with alcohol, pressed on a porous plate, and dried in the steam-oven. Weight, 11.5 grams.

The solution and washings were evaporated to dryness, and the crystals obtained were treated in the same way as the former fraction: 5.8 grams were obtained, making a total of 11.5 grams of barium ethylidenepropionate (7 grams of acid). As the barium salt of ethylacrylic acid is a gum, the former salt must be almost pure, and, by one esterification, it has been possible to obtain 8.3 grams of pure ethylacrylic acid and 7 grams of pure ethylidenepropionic acid from 19 grams of the mixture.

Transformation of Hydrosorbic Acid into $\alpha\beta$ -Hexenoic Acid and Purification of the Mixture Obtained by Partial Esterification.

Hydrosorbic acid was prepared as described by Sudborough and Thomas (Trans., 1910, 97, 2450) by the reduction of sorbic acid in alkaline solution by means of 3 per cent. sodium amalgam. 13.7 Grams of the acid were treated as described by Fittig (Annalen, 1894, 283, 117) with 266 c.c. of 20 per cent. sodium hydroxide solution, the solution being boiled under a reflux condenser for thirty-five hours: 10.27 grams of a yellow oil, presumably a mixture of $\alpha\beta$ -hexenoic and hydrosorbic acids, were obtained by steam distillation, and 3.1 grams of hydroxy-acid from the residue. The $\alpha\beta$ -hexenoic and hydrosorbic acids were separated as follows.

Experiment 15.—10.27 Grams of the mixture were treated with 60 c.c. of alcohol and 20 c.c. of 1.02*N*-alcoholic hydrogen chloride and left for five and a-half hours at 20°. The mixture was then separated by exactly the same method as that adopted in the previous experiments, the ester being very carefully freed from ether. Nine grams of ester, boiling at 170–172°/762 mm., were obtained. The aqueous solution was heated on a steam-bath to

remove ether and alcohol, and then evaporated to a small volume. On cooling, the $\alpha\beta$ -hexenoic acid was precipitated by addition of hydrochloric acid in excess, when 0.9 gram was obtained, which melted at $32.1-32.3^\circ$ (Fittig gives $32.7-33.1^\circ$ as the melting point of the pure acid). The aqueous filtrate was extracted three times with ether, the ethereal extract yielding 1.7 grams of acid, nearly all of which solidified—a trace of oil being observed.

Experiment 16.—The 9.0 grams of ester were first carefully hydrolysed and then boiled with sodium hydroxide as before for thirty-five hours. 5.83 Grams of the mixture of $\alpha\beta$ -hexenoic and hydrosorbic acids were obtained, and to this 34 c.c. of alcohol and 14 c.c. of 0.947*N* alcoholic hydrogen chloride were added, and the solution left for five and a-half hours. It was then poured into water, and treated as before, except that, the acid being only a small quantity, the solution of the sodium salt was evaporated so as to precipitate all the acid. 5.55 Grams of ester (b. p. $170-172^\circ$) and 0.4 gram of acid (m. p. $27.5-28.5^\circ$) were obtained.

Separation of $\alpha\beta$ - and $\gamma\delta$ -Unsaturated Acids.

$\alpha\beta$ -Hydrocinnamylidenemalonic acid,

was prepared as described by Riiber (*Ber.*, 1904, **37**, 2274; compare also *Trans.*, 1910, **97**, 2452).

To obtain the corresponding substituted acetic acid, this acid was boiled with water, as described by Riiber (*Ber.*, 1905, **38**, 2746). The oily δ -phenyl- Δ^4 -pentenoic acid obtained did not crystallise from light petroleum as stated by Riiber, and gave 188 as the mean of two determinations of its equivalent weight (δ -phenyl- Δ^4 -pentenoic acid = 176, corresponding hydroxy-acid = 194). Apparently there was some hydroxy-acid present. The oil was, however, without further purification used for treatment with sodium hydroxide solution, as described by Riiber, for conversion into a mixture of the isomeric $\alpha\beta$ -, $\beta\gamma$ -, and $\gamma\delta$ -acids with some hydroxy-acids; 13.2 grams of such a mixture were obtained, giving 4.1 grams of insoluble hydroxy-acid (m. p. $129-130^\circ$) and 8.7 grams of a mixture of $\alpha\beta$ -, $\beta\gamma$ -, and $\gamma\delta$ -acids on treatment with boiling carbon disulphide.

The mixture of unsaturated acids was pressed on a porous plate, the oily $\beta\gamma$ -acid being absorbed, and 5.5 grams of a mixture of $\alpha\beta$ - and $\gamma\delta$ -acids obtained. This was dried in a desiccator, and separated as follows.

Experiment 17.—Thirty-six c.c. of alcohol and 12 c.c. of 0.947*N* alcoholic hydrogen chloride were added to the 5.5 grams

of the mixture, the solution left for five and a-half hours at 50° and then poured into water and treated as before, 4.03 grams of ester being obtained.

The alkaline aqueous solution was evaporated to a small volume acidified with hydrochloric acid, the precipitated acid removed, and the filtrate extracted with ether: 1.75 grams of the $\alpha\beta$ -acid (m. p. 99—101°; Riither gives 104°) were obtained by precipitation whilst 0.12 gram remained in the flask after removal of ether from the ethereal extract.

The 4.03 grams of ester were hydrolysed, and the acid recovered in exactly the same way as that used for the $\alpha\beta$ -acid: 3.15 grams of acid (m. p. 79—82°; Sudborough and Thomas give 91°) were obtained by precipitation, and 0.4 gram from the ethereal extract. The latter contained a little oil, and when pressed on a glass plate melted at 126—128°; it was therefore probably the hydroxy-acid.

2.9 Grams of the acid (m. p. 79—82°) were recrystallised from light petroleum (b. p. 60—80°), a small quantity of insoluble matter being removed, and 1.75 grams of crystals, melting at 88—89°, and 0.85 gram, melting at 84—86°, were obtained.

ABERYSTWYTH.

CCLV.—*The Absorption Spectra of Various Iodine Derivatives of Benzene and Toluene as Vapours in Solution, and in Thin Films.*

By JOHN EDWARD PURVIS.

THE author has previously given accounts of investigations of the ultraviolet absorption spectra of the vapours of chloro- and bromo-benzene, of *o*- and *m*-dichloro- and dibromo-benzene, and of *o* and *m*-chloro- and bromo-toluene (this vol., pp. 811 and 1699).

The investigation has been continued with iodobenzene, *o*- and *m*-iodotoluene, and *o*- and *m*-di-iodobenzene. The apparatus employed and the general experimental method have been described before (*loc. cit.*).

Vapours.—Iodobenzene.

TABLE I.

The absorption spectrum of iodobenzene in a 1-dm. tube has been studied by Pauer (*Ann. Phys. Chem.*, 1897, [iii], 61, 363).

who observed two bands at λ 2625 and λ 2620. The author has studied the vapour of the substance at various temperatures and pressures in a column 200 mm. long and 20 mm. diameter. No such bands were observed, and the following table describes the absorption under the varying conditions of temperature and pressure

Pressure in mm.		
17	767	The rays were transmitted to the Cd line 2313, which was fairly strong
30	811	The rays were transmitted to the Cd line 2329; the Cd lines 2321 and 2313 were just visible
45	837	The rays were transmitted to about λ 2630, where they gradually faded away; the Cd line 2573 was weak, and the rays were then feebly transmitted from about λ 2500 to about λ 2350, where they were again absorbed.
60	867	The rays were transmitted to about λ 2700
75	897	The rays were transmitted to about λ 2850; the Cd line 2743 was just visible
90	927	The rays were transmitted to about λ 2930, and the Cd line 2831 was just visible

A careful search was made for the two bands described by Pauer, but none were found. The vapour showed no absorption bands at any of the temperatures and pressures employed, whereas a considerable number of absorption bands were found in the vapours of the corresponding chlorine and bromine compounds (*loc. cit.*).

The absorption phenomena of the vapours of *o*- and *m*-iodotoluene were also studied in a column 200 mm. long and 20 mm. diameter, and no bands were observed. The following tables (II and III) describe the phenomena observed at various temperatures and pressures.

o-Iodotoluene.

TABLE II.

Pressure in mm.		
17	766	The rays were transmitted to about λ 2300; the Cd line 2288 was just visible
30	810	The rays were transmitted to about λ 2310
45	836	The rays were transmitted to about λ 2340; the Cd lines 2329 and 2321 were just visible
60	866	The rays were transmitted to about λ 2400; they were very weak from about λ 2650 to λ 2500; the Cd line 2573 was not very strongly marked
75	896	The rays were transmitted to about λ 2800; the Cd line 2743 was very weak
90	926	The rays were transmitted to about λ 2900; the Cd line 2837 was just visible

2320 PURVIS: THE ABSORPTION SPECTRA OF VARIOUS IODINE

m-Iodotoluene.

TABLE III.

<i>t</i> °.	Pressure in mm.	
17°	763	The rays were transmitted to about λ 2330; the Cd lines 2329, 2321, and 2318 were visible
30	807	The rays were transmitted to about λ 2330; the Cd lines 2329 and 2321 were visible
45	833	The rays were transmitted to about λ 2360
60	863	The rays were transmitted to about λ 2670; the Cd line 2573 was only moderately strong
75	893	The rays were transmitted to about λ 2830; the Cd line 2748 was only moderately strong
90	923	The rays were transmitted to about λ 2900; the Cd line 2837 was just visible

Like the vapour of *o*-iodotoluene, the vapour of *m*-iodotoluene exhibited no absorption bands at any of the above temperatures and pressures, whereas a considerable number of bands were found in the vapours of the corresponding chlorine and bromine compounds (*loc. cit.*).

As regards the vapours of the two solids *o*- and *m*-diiodobenzene, the melting points of which are 27° and 40° respectively, each substance was introduced in the 200 mm. tube which was placed in the water-bath at 45°. Two series of experiments were taken, one under a constant diminished pressure and at various temperatures, and the other at varying pressures and temperatures. No bands were observed, and the tables IV, V, and VI describe the phenomena observed.

o-Diiodobenzene.

TABLE IV.

The following table describes the phenomena observed in the vapour of *o*-diiodobenzene at varying temperatures and constant pressure.

<i>t</i> °.	Pressure in mm.	
47	17	The rays were transmitted to λ 2250; the Cd lines 2194, and 2144 were visible
60	17	The rays were transmitted to λ 2250; the Cd lines 2265 and 2194 were visible
75	17	The rays were transmitted to about λ 2380; the Cd lines 2329 to 2265 were visible
90	17	The rays were transmitted to λ 2410; the Cd lines 2329 to 2265 were visible, but weaker than at 75°.

TABLE V.

The following table describes the phenomena observed in the vapour of *o*-diiodobenzene at varying temperatures and pressures.

	Pressure in mm.	
42	757	The rays were transmitted to about λ 2400; the Cd lines from 2329 to 2194 were visible
60	857	The rays were transmitted to λ 2550; the Cd lines 2329 to 2265 were very weak
75	887	The rays were transmitted to λ 2650; the Cd line 2573 was weak
90	917	The rays were transmitted to λ 2850; the Cd line 2748 was weak

m-Diiodobenzene.

TABLE VI.

The following table describes the phenomena observed in the vapour of *m*-diiodobenzene at varying temperatures and pressures.

	Pressure in mm.	
42	757	The rays were transmitted to λ 2240; the Cd lines 2194 and 2144 were visible
60	857	The rays were transmitted to λ 2450; the Cd lines 2329 to 2265 were weak
75	887	The rays were transmitted to λ 2550
90	917	The rays were transmitted to λ 2650; the Cd line 2573 was very weak

That is to say, no absorption bands were observed in the vapours of *o*- and *m*-diiodobenzene, whereas a considerable number of bands were found in the vapours of the corresponding *o*- and *m*-dichloro- and dibromo-benzenes (*loc. cit.*).

Solutions in Alcohol: Iodobenzene.

TABLE VII.

The absorption spectra of solutions of iodobenzene have been investigated by Pauer (*loc. cit.*), who found no bands. The author has studied the absorption spectra of various strengths of alcoholic solutions of iodobenzene, and table VI describes the phenomena observed.

2322 PURVIS: THE ABSORPTION SPECTRA OF VARIOUS IODIDES

Strength of solution.	Thickness of solution in mm.	Limit of transmitted rays, λ .
$M/10$	2	2820
	10	2980
	20	3050
	30	3080
$M/100$	2	2400
	10	2730
	20	2800
	30	2850
$M/1000$	2	2330
	10	2380
	20	2410
	30	2500

That is to say, no bands were observed in alcoholic solutions of iodobenzene, whereas alcoholic solutions of each of the corresponding substances chloro- and bromo-benzenes exhibited seven bands, the two most refrangible bands being very weak (*loc. cit.*).

The following table (VIII) describes the absorption of various alcoholic solutions of *o*- and *m*-iodotoluene.

TABLE VIII.

<i>o</i> -Iodotoluene.			<i>m</i> -Iodotoluene.		
Strength of solution.	Thickness of solution in mm.	Limit of transmitted rays, λ .	Strength of solution.	Thickness of solution in mm.	Limit of transmitted rays, λ .
$M/100$	2	2410	$M/100$	2	2410
	10	2770		10	2840
	20	2820		20	2870
	30	2860		30	2880
$M/1000$	2	2350	$M/1000$	2	2350
	10	2400		10	2420
	20	2420		20	2440
	30	2500		30	2500

No bands of selective absorption were observed in any of the solutions, whereas alcoholic solutions of the corresponding chloro- and bromo-toluenes exhibited two wide diffuse bands and a very weak doubtful band on the more refrangible side (*loc. cit.*).

The following table (IX) describes the absorption of various alcoholic solutions of *o*- and *m*-di-iodobenzene.

TABLE IX

<i>o</i> -Di-iodobenzene.			<i>m</i> -Di-iodobenzene.		
Strength of solution.	Thickness of solution in mm.	Limit of transmitted rays. λ .	Strength of solution.	Thickness of solution in mm.	Limit of transmitted rays. λ .
<i>M</i> /100	2	2750	<i>M</i> /100	2	2730
	10	2980		10	2950
	20	3130		20	2990
	30	3240		30	3050
<i>M</i> /1000	2	2480	<i>M</i> /1000	2	2420
	10	2550		10	2470
	20	2690		20	2570
	30	2840		30	2750

No bands of selective absorption were observed, whereas alcoholic solutions of each of the corresponding dichloro- and dibromobenzenes showed four well-marked bands (*loc. cit.*); the fourth most refrangible band in each of the dibromobenzenes was very weak and difficult to distinguish.

Liquids in Thin Films.

Each liquid was pressed between two quartz plates, and held rigidly in front of the slit of the spectroscope. The radiant energy of the Cd spark was passed through the thin films for various periods of time varying from one minute to five minutes. As regards the two solids *o*- and *m*-di-iodobenzenes, the melting points of which are 27° and 40° respectively, a few crystals of each substance were placed on one of the quartz plates, which was warmed just to the melting point of the substance, and the other quartz plate was then pressed closely over the liquid. There was no crystallisation of either substance while the absorption was being photographed. The following table gives the limits of the transmitted rays through thin films of the various substances.

TABLE X.

	Time of exposure in minutes.	Limit of transmitted rays. λ .
Iodobenzene	5	2800
<i>o</i> -Iodotoluene	5	2780
<i>m</i> -Iodotoluene	5	2820
<i>o</i> -Di-iodobenzene	5	2900
<i>m</i> -Di-iodobenzene	5	2850

In no case was any absorption band observed; whereas thin films of the corresponding chloro- and bromo-benzenes showed seven bands, the most refrangible in each case being very weak; the *o*- and

m-chloro- and bromo-toluenes showed two well-marked bands and a doubtful more refrangible third; the *o*- and *m*-dichloro- and -dibromo-benzenes showed three well-marked bands and a doubtful more refrangible fourth; and toluene exhibited three bands (*loc. cit.*).

Results and Conclusions.

The results of the preceding observations prove that in the ultra violet regions neither the vapours, nor the alcoholic solutions, nor the thin films of the iodine derivatives of benzene or of toluene exhibit any bands of selective absorption, whereas the corresponding chlorine and bromine compounds have a well-marked series of bands under similar physical conditions.

The decrease in the number of vapour bands when the number and weight of the side-chains are increased is analogous to that observed by Hartley in the case of benzene and its homologues (*Phil. Trans.*, 1908, A, 208, 475); for example, the maximum number of bands found in benzene by Hartley was 84, in toluene 22, in ethylbenzene 19, in *o*-xylene 23, in *m*-xylene 41, in *p*-xylene 30, in cymene 9, and in mesitylene 4. In the halogen derivatives the maximum number of bands found by the author (*loc. cit.*) in the vapour of chlorobenzene was 72, in bromobenzene 62, in *o*-dichlorobenzene 29, in *m*-dichlorobenzene 35, in *o*-dibromobenzene 30, in *m*-dibromobenzene 13, in *o*-chlorotoluene 23, in *m*-chlorotoluene 20, in *o*-bromotoluene 15, and in *m*-bromotoluene 13, so that the chief controlling factors are the type, weight, and orientation of the introduced radicles. Now when the heavy iodine atom takes the place of either chlorine or bromine, the bands completely disappear, and there is no selective absorption. Analogous phenomena are observed in the bands of the alcoholic solutions and of the thin films of these various substances. The few broad diffuse bands observed in the solutions and in the thin films of the chlorine and bromine derivatives completely disappear in the solutions and the thin films of the corresponding iodine compounds. At the same time, the differences in the positions where general absorption begins in equimolecular solutions of the ortho- and meta-compounds indicate that the orientation of the side chain is a factor in determining the extent of the general absorption.

In previous communications (*loc. cit.*) the author has suggested an explanation to account for the facts observed in the chlorine and bromine compounds of benzene and toluene; and the phenomena observed in the corresponding iodine compounds appear to support that explanation. The heavy iodine atom is the controlling force, and it damps and dislocates the movements of the atoms of the benzene nucleus as well as the alkyl side-chains, so that the

Physical oscillations or vibrations are destroyed, and no selective absorption is possible. The dislocation of the oscillations occurs, not only when the vibrations are restricted, as in the alcoholic solutions and in the thin films, but also in the vapours where the vibrations are not subjected to any external forces except those of variations of temperature and pressure. Besides the mass of the atom, the action of the radiant energy may be a considerable factor in the final result; because each atom will absorb an amount of energy dependent on its intrinsic characters, and this will react on its own vibrations and on the vibrations of the other atoms. The final adjustment, therefore, will depend on the balance of a complex series of disturbances, and the forces which determine these include such factors as the number, the mass, the intrinsic characters, and the orientation of the atoms of both the nucleus and the side-chains; the physical conditions of the vibrating system as vapours or in solution or as liquids at various temperatures and pressures; and on the distribution and reaction of the vibrations consequent on the absorption of the radiant energy by the various oscillating atoms and atomic groups.

The author is engaged in a comparative study of naphthalene and anthracene and their derivatives, the results of which will be submitted later; and he desires to thank again the Government Grant Committee of the Royal Society, by whose assistance the larger portion of the cost of the apparatus was defrayed.

UNIVERSITY CHEMICAL LABORATORY,
CAMBRIDGE.

CCLVI. — *Influence of Double Linking on Optical Activity; Some n-Propyl and Allyl Derivatives of Menthol.*

By PERCY FARADAY FRANKLAND and HUGH HENRY O'SULLIVAN.

IN connexion with the problem of ascertaining the influence of double linking on optical activity it has been shown by one of us that both in the substitution of tartramide and of malamide by n-propyl and by allyl respectively the resulting n-propylamides have higher molecular rotations than the corresponding allylamides (P. Frankland and Twiss, *Trans.*, 1906, **89**, 1854; and P. Frankland and Done, *Trans.*, 1906, **89**, 1861), which is contrary to the generally

accepted rule that unsaturated groupings bring about a higher rotation than the corresponding saturated ones. This rule is based on results obtained in a number of investigations made during the past thirteen years by Tschugaeff (*Centralbl.*, 1898, 69, I. 404; 1902, 73, II., 1238), Haller, Rupe (for many references, literature see *Trans.*, 1903, 83, 1351), Hilditch (*Trans.*, 1908, 93, 1909, 95, 1910, 97, 1911, 99; *Zeitsch. physikal. Chem.*, 1911, 77, 482), and others.

The present communication contains data obtained in the further investigation of this subject.

The compounds which we have prepared are three pairs of *n*-propyl and allyl derivatives of menthol; they were all liquids, and their rotations were determined at a number of different temperatures between 15° and 100°. Their rotations have also been determined in methyl alcohol solution.

In the following table we have recorded the values for $[M]_D^{20}$ in the liquid state, whilst we have included for comparison the corresponding values for some other *n*-propyl and allyl compounds.

	B. p.	$[M]_D^{20}$ in liquid state
Menthoxyacetic allylamide,	185--187°/14 mm.	- 192.5*
Menthoxyacetic propylamide	188--189°/16 mm.	193.7
Allyl menthoxyacetate	182°/40 mm.	234.4
Propyl menthoxyacetate	172°/26 mm.	234.1
Menthyl allylaminoacetate	155--157°/17 mm.	169.5
Menthyl propylaminoacetate	159--161°/17 mm.	158.3
Menthyl allyl ether *	—	{ $[M]_D^{20}$ - 192.5 }
Menthyl propyl ether †	—	{ $[M]_D^{20}$ - 192.5 }
		$[M]_D^{20}$
	M. p.	in pyridine solution
Tartaric allylamide ‡	183°	+ 251*
Tartaric propylamide ‡	216	+ 280
Malic allylamide §	117.5	- 72.7
Malic propylamide §	126	90.5

* Haller and Marsch (*Compt. rend.*, 1904, 138, 1665).

† Tschugaeff (*Centralbl.*, 1902, 11, 1238).

‡ Frankland and Twiss (*loc. cit.*).

§ Frankland and Done (*loc. cit.*).

In the case of the amides of menthoxyacetic acid the allyl compound is seen to have the lower molecular rotation, but the difference is very small. This difference is practically the same over the range of temperature at which the observations were made. In this case the double linking diminishes the rotatory power, and agrees in this respect with the results obtained with the tartaric and malic amides.

The allyl and propyl esters of menthoxyacetic acid have practically identical molecular rotations at 20°, but whilst below 35° the

rotation of the allyl is very slightly in excess of that of the propyl compound, above that temperature the relation is reversed (see diagram).

In the case of the next pair, menthyl allylaminoacetate and propylaminoacetate, the allyl compound has slightly the higher molecular rotation throughout the whole range of temperature over which the observations were made.

Molecular rotation curves of the six compounds.

The results recorded in this paper lead to some general considerations:

(1) The extremely small differences between the molecular rotations of the pairs of allyl and propyl compounds described may be accounted for by the great distance of the unsaturated grouping in the allyl from the nearest asymmetric carbon atom in the menthyl radicle; thus, in menthoxyacetic allylamide, in allyl menthoxyacetate, and in menthylallylaminoacetate there are, in each case, *five atoms intervening between the unsaturated carbon atom of the allyl and the nearest asymmetric carbon atom of the menthyl*. That a constitutional change (such as passing from allyl to propyl)

made at such a great distance from the asymmetric carbon atom should have but little effect on the rotation is in accordance with the conclusions arrived at by P. Frankland and MacGregor (Trans. 1896, 69, 121), and since confirmed by many other workers.

(2) Much greater differences in the molecular rotations of the following pairs of allyl and propyl compounds have been observed:

Liquid state.	Menthyl allyl ether	$[\alpha]_D^{19} - 192.5^\circ$	Difference 10.
	Menthyl propyl ether	$[\alpha]_D^{19} - 182.5^\circ$	

In the menthylallyl ether there are only two atoms intervening between the unsaturated carbon atom of the allyl and the nearest asymmetric carbon atom of the menthyl group.

Pyridine solution.	Tartaric allylamide	$[\alpha]_D^{20} + 251^\circ$	Difference = 38½
	Tartaric propylamide	$[\alpha]_D^{20} + 289^\circ$	
	Malic allylamide	$[\alpha]_D^{20} - 72.7^\circ$	Difference = 17
	Malic propylamide	$[\alpha]_D^{20} - 90.5^\circ$	

In each of the two allyl compounds there are 3 atoms intervening between the unsaturated carbon of one allyl group and 4 atoms between that of the other allyl group and the asymmetric carbon atom of the tartaric and malic radicles respectively.

We do not think that any comparisons between the quantitative differences obtained in the case of the menthyl ethers on the one hand, and the amides of tartaric and malic acids respectively on the other, would be justifiable, first, because of the entirely different nature of the asymmetric nuclei concerned in the two cases, and secondly, because the rotations of the menthyl ethers were determined in the liquid state, whilst those of the tartaric and malic amides were taken in solution, and a great variation was found in the differences between the rotations of the propyl and allyl amides according to the particular solvent employed (pyridine, methyl alcohol, water, and glacial acetic acid) (see Frankland and Twiss, Trans., 1906, 89, 1853, and Frankland and Done, Trans. 1906, 89, 1860).

(3) It will be seen that the menthoxyacetic grouping gives rise to a much higher molecular rotation than the menthyl aminoacetate grouping, and that the propyl and allyl esters of menthoxyacetic acid again have higher rotations than the corresponding propyl- and allyl-amides.

(4) In this connexion the following relations are worthy of note

	$[\alpha]_D^{20}$
Menthyl allylaminoacetate	160.5
Menthyl propylaminoacetate	158.3
Menthyl propionate *	160.2
* Normal constant of the menthyl homologous fatty esters * ..	157.8
Menthyl phenylpropionate *	161.9

* Tschugaeff.

Thus, such profound differences in constitution as exist between the fatty acids on the one hand and the substituted amino-fatty acids on the other are attended with practically no alteration in the molecular rotation. These changes in constitution are ineffective, because occurring at a point remote from the asymmetric grouping.

Again, the greater rotatory effect of the menthyl ether than of the menthyl ester grouping which we have found is in accordance with similar results obtained by Tschugaeff, thus:

	$[\alpha]_D^{20}$
Menthyl methyl ether	162.6
Menthyl ethyl ether	179.0
Menthyl propyl ether	182.5
Menthyl benzyl ether	232.7
Menthyl formate	116.3
Menthyl acetate	157.3
Menthyl propionate	160.2
Menthyl n-butyrate	158.9
Menthyl n-octate	157.3
Methoxyacetic allylamide	192.5
Methoxyacetic propylamide	193.7
Methoxyacetic allyl ester	234.4
Methoxyacetic propyl ester	234.1
Menthyl allylaminoacetate	160.5
Menthyl propylaminoacetate	158.3

From the above figures it will be seen incidentally that the acetic allyl ester and acetic propyl ester groupings have almost exactly the same rotatory effect as is exerted by the benzyl radicle in the series of menthyl ethers.

This greater rotatory effect of the menthyl ether than of the menthyl ester grouping is in reality a further illustration of what has been pointed out by Purdie and Irvine (Trans., 1901, 79, 964) in respect of ethyl malate, ethyl monomethoxysuccinate, and ethyl acetylmaleate on the one hand, and in respect of ethyl tartrate, ethyl dimethoxysuccinate, and ethyl diacetyltartrate on the other, and by P. Frankland and Gehhard (Trans., 1905, 87, 864) in respect of the alkyl glycerates, alkyl dimethoxypropionates, and alkyl diacetylglycerates. In all of these cases the effect on molecular rotation of alkylating the OH-group attached to an asymmetric carbon atom is much greater than that produced by acetylating the same group.

EXPERIMENTAL.

Methoxyacetic Acid, $C_{10}H_{19}O \cdot CH_2 \cdot CO_2H$.—Two hundred grams of menthol (Kahlbaum) were dissolved in about 500 c.c. of sodium-dried benzene in a 3-litre, round-bottom flask. Forty grams of

sodium cut up into thin plates were then added, and the flask was heated under a reflux condenser on a boiling-water bath for two hours. The excess of sodium was then removed (only 30 grams being required by 200 grams of menthol), and 50 grams of chloroacetic acid, dissolved in about 400 c.c. of dry benzene, were then added gradually, the flask being well shaken during the addition to keep the precipitated sodium chloroacetate in a finely divided state, and cooled when necessary to prevent violent boiling during the reaction. The result of this is to produce a gelatinous precipitate of sodium chloroacetate, on which the sodium menthoxyacetate is able to react to form the sodium salt of menthoxyacetic acid. It is apparent that two molecules of sodium menthoxyacetate are present for every molecule of chloroacetic acid, as the reaction takes place in two stages:

In the actual preparation the quantities taken were in the proportion of $2\frac{1}{2}$ molecules of sodium menthoxyacetate to 1 molecule of chloroacetic acid. At first sight it would seem to be more economical were the sodium chloroacetate prepared in some other way instead of utilising sodium menthoxyacetate as in the first equation, but this is practically the only serviceable way, and the excess of menthol is easy to recover.

The flask was then heated under a reflux condenser for two or five hours on a boiling-water bath. During this time the precipitated sediment was periodically broken up by vigorous shaking, and dry benzene to the extent of $1\frac{1}{2}$ litres added at intervals to keep the mixture in a sufficiently liquid condition.

The sodium menthoxyacetate was then washed out with water which also dissolves the sodium chloride, sodium hydroxide, and any free chloroacetic acid. The menthol remains in the benzene layer, as well as any tarry products if formed. The aqueous solution of sodium menthoxyacetate was acidified with sulphuric acid, and the free menthoxyacetic acid extracted with ether. The extract after being dried was concentrated to a syrup, which crystallised out in the refrigerator. The crystals were washed free from mother liquor with a little ether, and dried on porcelain.

This product was almost colourless, and melted only 3° below that of the purified acid. The total yield of this crude acid was 85 grams, which is 75 per cent. of the theoretical quantity obtainable from the chloroacetic acid used.

The acid is very soluble in all organic solvents; it was purified by repeated recrystallisation from ether. After six such crystallisations

INFLUENCE OF DOUBLE LINKING ON OPTICAL ACTIVITY. 2331

the melting point was 53—54°, and the rotation in methyl alcohol at 20° was:

t	p	D_4^{20}	c	α_D^{20}	$[\alpha]_D^{20}$	$[M]_D^{20}$
25.3	5.253	0.8030	4.218	-7.84°	-92.93°	198.8°

For the following preparations the acid was used after one crystallisation.

Menthoxycetic Allylamide.—Ethyl menthoxyacetate was prepared by esterifying 60 grams of menthoxyacetic acid in an excess of absolute alcohol by saturation with dry hydrogen chloride. After waiting for an hour, hydrogen chloride was again passed in, and the heating continued for another hour, after which the mixture was washed with a dilute solution of sodium carbonate, and the ester extracted with ether. After drying the extract, the ether was distilled over, and the ester distilled in a vacuum. The yield was 40 grams.

Fifteen grams of allylamine (Kahlbaum) were added, and the mixture heated under a reflux condenser on a water-bath for eight hours. The liquid product was purified by vacuum distillation until the observed rotation was constant. The yield was about 20 grams. After four distillations, the liquid boiled at 185—187°/14 mm., and gave d_4^{20} 0.9667.

The amide is a colourless, odourless, oily liquid, soluble in all organic solvents, but not in water or acids:

1.166 gave 7.3 c.c. N_2 (moist) at 19° and 744.7 mm. $N=5.61$.

$C_{15}H_{27}O_2N$ requires $N=5.53$ per cent.

Menthoxycetic Propylamide.—This was prepared in an identical manner to the allylamide from 45 grams of the ester and 12 grams of propylamine (Kahlbaum). After five distillations the observed rotation not being constant, and there being only 12 grams of the purest fraction, a second preparation of the amide was commenced, and after five vacuum distillations was added to the first preparation. When the whole had been distilled three more times, the observed rotation became constant. The yield from the two preparations was 20 grams.

This pure substance boiled at $188-189^{\circ}/16$ mm., and gave $[\alpha]_D^{20} -75.96^{\circ}$. It is a colourless, odourless, oily liquid, similar in properties to the allylamide:

0.1410 gave 7.0 c.c. N_2 (moist) at 17.5° and 748.6 mm. N 5.52
 $C_{15}H_{25}O_2N$ requires $N=5.49$ per cent.

Allyl Menthoxycetate.—Sixty-five grams of menthoxycetic acid (1 mol.) and 57 grams of allyl alcohol (3 mols.) were mixed in a flask and saturated with dry hydrogen chloride. After heating on a water-bath for a short time, more hydrogen chloride was passed in, and the mixture again heated for an hour. The mixture was then washed with a solution of sodium carbonate, and the ester and excess of allyl alcohol extracted with ether. This extract was dried and the ether and alcohol distilled off. The ester was then distilled in a vacuum until the observed rotation was constant at 15° in a 0.5-dm. tube. After seven distillations the ester boiled at $152^{\circ}/40$ mm., and gave $[\alpha]_D^{15} -93.04^{\circ}$. The yield was 20 grams.

INFLUENCE OF DOUBLE LINKING ON OPTICAL ACTIVITY. 2333

This ester is a colourless, odourless, oily liquid, soluble in all organic solvents:

0.2758 gave 0.7130 CO₂ and 0.2559 H₂O. C=70.51; H=10.31.

C₁₅H₂₂O₃ requires C=70.87; H=10.23 per cent.

Propyl Menthoxyacetate.—The propyl alcohol used had to be fractionated, as it boiled over a range of ten degrees, 93–103°. The fraction boiling at 96.5–97.5° was used for this preparation.

This ester was prepared in a similar manner to the above, excess of the alcohol to the extent of 3 molecules to 1 molecule of the menthoxyacetic acid being taken.

Seventy grams of the acid were esterified with 60 grams of propyl alcohol by means of dry hydrogen chloride, as for the above ester.

The crude ester, after seven distillations in a vacuum, had a constant rotatory power, [a]_D²⁰ -91.46°, and boiled at 172°/26 mm. The yield was 19 grams.

The ester is a colourless, odourless, oily liquid, soluble in all organic solvents, but not in water:

0.2588 gave 0.6660 CO₂ and 0.2558 H₂O. C=70.18; H=10.98.

C₁₅H₂₂O₃ requires C=70.31; H=10.93 per cent.

Menthyl Allylaminoacetate.—Forty grams of menthyl chloroacetate, prepared from menthol and chloroacetic acid by esterification with dry hydrogen chloride, were dissolved in 100 c.c. of solvent-dried ether, and 20 grams of allylamine were added. The mixture was heated under a reflux condenser for three hours on a water bath. The interaction takes place readily, as after a few seconds crystals of allylamine hydrochloride were seen. It is necessary to take twice the quantity of amine required to replace the chloride in the menthyl chloroacetate in order to combine with the hydrogen chloride split off.

The amine hydrochloride was quickly collected, and washed with a little dry ether. The weight—15 grams—showed that the reaction was complete. The ether and any excess of amine was distilled off, and the crude ester distilled in a vacuum until the observed rotation became constant. After four distillations the ester boiled at 155–157°/17 mm., and gave $[\alpha]_D^{20} = -63.47$. The yield was 12 grams.

The ester is a colourless, odourless liquid, soluble in all organic solvents:

0.3552 gave 0.9206 CO_2 and 0.3374 H_2O . $\text{C} = 70.70$; $\text{H} = 10.77$; $\text{N} = 18.53$.
 0.2570 „ 12.9 c.c. N_2 (moist) at 20° and 739.4 mm. $\text{N} = 18.53$.
 $\text{C}_{15}\text{H}_{27}\text{O}_2\text{N}$ requires $\text{C} = 71.15$; $\text{H} = 10.67$; $\text{N} = 5.53$ per cent.

CHEMICAL LABORATORIES, UNIVERSITY,
EDGBASTON, BIRMINGHAM.

CCCLVII.—*The Constitution of Ergothioneine; a Betaine Related to Histidine.*

By GEORGE BARGER and ARTHUR JAMES EWINS.

Two years ago Tanret (*J. Pharm. Chim.*, 1909, [vi], **30**, 145) isolated from ergot a new crystalline base containing sulphur, and having the formula $C_9H_{15}O_2N_2S$. The description of the base given by Tanret suggested to us a possible relationship to the amino acid histidine; thus ergothioneine, as the new base was called by Tanret, is precipitated by mercuric chloride, and forms a compound with silver. These properties, together with the large nitrogen content, were strongly suggestive of the presence of a glyoxaline ring. Since one of us in conjunction with H. H. Dale (*Trans.*, 1910, **97**, 112), had already isolated another histidine derivative from ergot, namely 4(or 5)- β -aminoethylglyoxaline, a substance of great physiological activity and interest, we prepared a small quantity of ergothioneine according to Tanret's method, and found that, like histidine and many other glyoxaline derivatives, it gives an intense red coloration with sodium *p*-diazobenzenesulphonate, thus still further supporting our surmise with regard to the constitution of this base.

Ergothioneine contains (in addition to the sulphur atom) three carbon atoms and six hydrogen atoms more than histidine. This might well result from the substitution of three hydrogen atoms of histidine by methyl groups in such a manner that ergothioneine would be a new member of the class of methylated amino-acids or betaines, of which a number of examples are now known to occur in plants. This hypothesis proved to be correct; the substance is indeed a betaine, and almost certainly β -2-thiolglyoxaline-4(or 5)-propionbetaine (I). Like other betaines it has no marked physiological action.

On boiling with a concentrated (50 per cent.) aqueous solution of potassium hydroxide, the base is decomposed quantitatively into

dimethylamine and a yellow acid of the composition $C_6H_6O_2N_2S$, which represents the whole of the remaining atoms in the molecule, and the constitution of which is represented by (II). On boiling with dilute nitric acid, the sulphur atom of this acid is completely removed, and a new acid, β -glyoxaline-4(or 5)-acrylic acid (III), is formed. This acid on reduction yields β -glyoxaline-4(or 5)-propionic acid (IV), and we were able to identify both the saturated and the unsaturated acid by comparison with synthetic specimens. The various reactions will be best seen from the following scheme:

The only doubtful point remaining was with regard to the position of the sulphur atom. There are two probable positions, namely, attachment to the β -carbon atom of the side-chain or to the carbon atom in the 2-position in the glyoxaline ring, and choice between these two, although decisive, is based on analogy rather than on direct evidence; indeed, synthesis seems to be the only means of supplying complete proof.

The sulphur in ergothioneine reacts in every way like that of the thiolglyoxalines, and quite different from that in cystein, with which it might be expected to show analogies if attached to the β -carbon atom of the side-chain; thus the sulphur in cystein, as is well known, is readily eliminated by boiling with sodium hydroxide, whereas, as was stated above, the sulphur of ergothioneine is not removed by boiling with the strongest solutions of potassium hydroxide. On the other hand, the sulphur atom, like that of the thiolglyoxalines, is readily and quantitatively oxidised by ferric chloride (as recently employed by Pyman) or by bromine water to sulphuric acid, whereas in the case of cystein a sulphonic acid results, in which the sulphur still remains attached to the carbon atom. The only oxidising agent which acts similarly on cystein and ergo-

thioneine is iodine, which oxidises both to a compound, in which two sulphur atoms are directly linked. That obtained from ergothioneine has the constitution (V).^{*} A further argument for considering ergothioneine to be a thioglyoxaline derivative is the fact that, like other betaines, it is a feeble mono-acid base, whereas we should expect it to be di-acid if it, like histidine, contained a simple glyoxaline ring. The basic properties of the ring are destroyed by the presence of the sulphur atom as in other thioglyoxalines (compare, for instance, 2-thiol-4(or 5)-aminomethylglyoxaline, which forms a mono-hydrochloride, and was recently described by Pyman, *Trans.*, 1911, **99**, 672).[†]

Treatment of ergothioneine with ferric chloride gave trimethyl histidine (VI), a betaine which may possibly occur in nature.

EXPERIMENTAL.

The Action of Boiling 50 per cent. Aqueous Potassium Hydroxide on Ergothioneine.

0.88 Gram of ergothioneine was boiled with 20 c.c. of a 50 per cent. aqueous solution of potassium hydroxide, the distillate being collected in a known volume of *N*-hydrochloric acid. Distillation was continued until the evolution of alkaline vapours was practically complete. It was found that 3.1 c.c. of *N*-hydrochloric acid had been neutralised, corresponding with 80 per cent. of the theoretical for the evolution of one nitrogen atom. The main part of the distillate was evaporated to dryness, and the residue dissolved in a little alcohol and treated with an alcoholic solution of platinum chloride, when trimethylamine platinumchloride (m. p. 241°) separated. (Found, Pt=36.9. Calc., Pt=36.9 per cent.)

One nitrogen atom was thus shown to be evolved as trimethylamine. The strongly alkaline residue in the flask was rendered acid to Congo-red, when there was at once precipitated a yellow amorphous solid, β -2-thioglyoxaline-4-acrylic acid.

This acid was found to be characterised by its general insolubility

^{*} This iodide will be described later. It was already obtained by Tannan, who did not, however, appreciate its true significance. It forms black, steel-blue mixed crystals with iodine, a peculiar and extremely rare property which has so far only been observed in the case of cholic acid, narceine, and saponarin, and is closely analogous to the adsorption of iodine by starch. For this reason Tannan, who analysed the compound, did not obtain results in agreement with any simple formula.

[†] Dr. Pyman has since informed us of his recent observation that the glyoxalines are sharply differentiated from thioglyoxalines by the fact that they at once decolorise a dilute cold solution of potassium permanganate; we find that ergothioneine also does this, but histidine does not, nor does cystine.

is only moderately soluble in pyridine, and almost insoluble in all other ordinary organic solvents. The acid was crystallised for analysis by making a very dilute solution (0.1 per cent.) of the sodium salt, and acidifying. After three or four hours the acid began to separate, and precipitation was complete in about thirty-six hours. The acid obtained in this way separated in clusters of small prisms, which did not melt below 275° :

0.1179 gave 0.1805 CO_2 and 0.0420 H_2O . $\text{C}=41.8$; $\text{H}=3.9$.

$\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{S}$ requires $\text{C}=42.3$; $\text{H}=3.5$ per cent.

By oxidation by means of dilute nitric acid as described below, 10 per cent. of the theoretical amount of sulphur was obtained from the filtrate as barium sulphate.

14. Action of Boiling Dilute Nitric Acid on β -2-Thiolglyoxaline-4-acrylic Acid.

0.4 Gram of amorphous β -2-thiolglyoxaline-4-acrylic acid was added in small portions to 20 c.c. of 10 per cent. aqueous nitric acid. The mixture was kept gently boiling on a sand-bath for some minutes after solution was complete, and then allowed to cool. The crystalline nitrate of β -glyoxaline-4(or 5)-acrylic acid separated out, which after washing and drying melted at 198° with explosive decomposition. The yield was 0.28 gram:

0.1114 gave 0.1470 CO_2 and 0.0404 H_2O . $\text{C}=36.0$; $\text{H}=4.0$.

$\text{C}_6\text{H}_5\text{O}_2\text{N}_2, \text{HNO}_3$ requires $\text{C}=35.8$; $\text{H}=3.5$ per cent.

β -Glyoxaline-4(or 5)-acrylic acid was most readily obtained from the nitrate by the addition of one equivalent of sodium carbonate sand to a concentrated aqueous solution of the salt, when the acid separates at once as a crystalline solid, which after recrystallisation from dilute acetone was quite pure, and melted at $195-196^{\circ}$:

0.1776 gave 0.3474 CO_2 and 0.0712 H_2O . $\text{C}=53.3$; $\text{H}=4.4$.

$\text{C}_6\text{H}_5\text{N}_2\text{O}_2$ requires $\text{C}=52.2$; $\text{H}=4.3$ per cent.

β -Glyoxaline-4(or 5)-acrylic acid is moderately soluble in cold, but very readily so in hot, water. Its solutions give an intense red colour with sodium *p*-diazobenzenesulphonate.

The *phosphotungstate* is readily soluble in hot water or cold acetone, and crystallises in small, rectangular plates from dilute acetone.

The *picrate* forms golden-yellow prisms, melting at $213-214^{\circ}$, and sparingly soluble in cold water. The melting point of this picrate

remained unchanged when mixed with a synthetic specimen. The latter was obtained in small quantity by the action of trimethylamine on α -chloro- β -glyoxaline-4(or 5)-propionic acid.

The Reduction of β -Glyoxaline-4(or 5)-acrylic Acid to β -Glyoxaline-4(or 5)-propionic Acid.

β -Glyoxaline-4(or 5)-acrylic acid was dissolved in a little absolute alcohol, and the hot solution treated with five to six atomic proportions of sodium. The solution was then acidified with hydrochloric acid, and the precipitated salt collected. The filtrate and washings were evaporated to dryness, the residue dissolved in 5 per cent. aqueous sulphuric acid, and precipitated with phosphotungstic acid. The precipitate was treated with acetone, filtered from undissolved material, and the soluble phosphotungstate decomposed in the usual manner. On concentrating the final filtrate a crystalline acid separated, which after recrystallisation melted at 202° . When mixed with a specimen of synthetic β -glyoxaline-4(or 5)-propionic acid (m. p. 202°), the melting point remained unaltered. The acid obtained on reduction was therefore proved to be β -glyoxaline-4(or 5)-propionic acid.

The Action of Ferric Chloride on Ergothioneine. Formation of β -Glyoxaline-4(or 5)-picricbetaine (Histidine-betaine).

One gram of ergothioneine was boiled for one hour with an aqueous solution containing nine molecular proportions of ferric chloride. The iron was removed from solution by sodium carbonate, the filtrate acidified with sulphuric acid (so as to give a 5 per cent. solution of the latter), and precipitated by phosphotungstic acid. The precipitate, which was completely soluble in acetone, was decomposed in the usual way, and the barium and sulphuric acid removed. The filtrate was concentrated, and treated with a hot aqueous solution of picric acid. On cooling, a crystalline picrate separated, which after recrystallisation from water was obtained in deep yellow prisms melting at 123° :

0.1340 gave 0.1908 CO_2 and 0.0396 H_2O . $\text{C}=38.4$; $\text{H}=3.5$.

$\text{C}_9\text{H}_{15}\text{O}_2\text{N}_3(\text{C}_6\text{H}_3\text{O}_7\text{N}_3)_2$ requires $\text{C}=38.5$; $\text{H}=3.3$ per cent.

The *dipicrate* is very sparingly soluble in cold, fairly readily so in hot, water.

The *picrolonate* prepared in the usual way forms long, thin orange-yellow needles, melting at 229 — 230° .

The *aureichloride* separated from dilute aqueous hydrochloric acid as large, broad, deep orange-yellow prisms, melting at 171° .

In conclusion, we wish to express our indebtedness to Dr. F. L. TYMAN for synthetic specimens of α -chloro- β -glyoxaline-4(or 5)-propionic and β -glyoxaline-4(or 5)-propionic acids for purposes of comparison, and to the Wellcome Chemical Works, Dartford, for a supply of ergothioneine.

ROCKWELL HALL, HERNE HILL, LONDON, S.E.

XLVIII.—*Derivatives of o-Xylene. Part I. 3-Nitro-o-xylene and 3:6-Dinitro-o-xylene.*

By ARTHUR WILLIAM CROSSLEY and GERTRUDE HOLLAND WREN.

IN 1909 an account of the preparation and properties of 3-nitro-o-xylene was published (Trans., 95, 208). The method adopted for its isolation (*ibid.*, p. 216) consisted in treating *o*-xylene with a mixture of nitric and sulphuric acids and separating the two mono-nitro-*o*-xylenes from the dinitro-*o*-xylenes by distillation. The mixture of 3- and 4-nitro-*o*-xylenes was then distilled fractionally, and each fraction cooled, when 4-nitro-*o*-xylene separated as a yellow solid, melting at 30°. After repeating this process several times, the residual liquid product was refracted, when finally an oil, boiling at 131°/20 mm., was obtained, which was proved to be 3-nitro-*o*-xylene by the fact that it gave on oxidation an almost quantitative yield of 3-nitrophthalic acid. Nevertheless, the method of preparation is not without objection, for despite the numerous fractional distillations carried out, it is possible that the resulting 3-nitro-*o*-xylene might contain a small quantity of 4-nitro-*o*-xylene dissolved in it, and it seemed of interest to prepare 3-nitro-*o*-xylene by some other method, in which the isomeric 4-nitro-*o*-xylene would not be produced, and to compare the physical constants of the two specimens of 3-nitro-*o*-xylene.

The method adopted was to replace the amino-group in 3-nitro-*o*-4-xylydine (II) by hydrogen:

3-Nitro-*o*-4-xylydine (II) has been described by Noelting, Braun, and Thesmar (*Ber.*, 1901, 34, 2249), and that these authors orien-

tated this compound correctly receives confirmation from the experiments now described. They prepared it by the action of a mixture of nitric and sulphuric acids on *o*-4-xylydine. The substance may be more easily obtained by reducing 3:4-dinitro-*o*-xylene (I) with alcoholic stannous chloride, for which purpose 10 grams of 3:4-dinitro-*o*-xylene (Trans., 1909, 95, 219) was suspended in 75 c.c. of absolute alcohol, and a solution of 10 grams of stannous chloride in 200 c.c. of absolute alcohol, saturated with dry hydrogen chloride, gradually added, the temperature being maintained between 10° and 12°. After remaining twenty-four hours the major portion of the alcohol was evaporated, and the residue poured into water, when on some occasions it was found necessary to filter from a small amount of unchanged dinitro-*o*-xylene. Solid potassium hydroxide was then added until the precipitate originally formed, redissolved, when the nitroamine separated. This was extracted with ether, etc., when the residue, weighing 7.5 grams, solidified. It was purified by crystallisation from dilute alcohol, yielding 4.6 grams of 3-nitro-*o*-4-xylydine (compare Noetting, Ber. and Thesmar, *loc. cit.*) as scarlet-coloured needles, melting at 65–66°. On evaporating the alcoholic mother liquor and subjecting the residue to steam distillation, a further 1.3 grams of pure nitroamine were isolated, thus making the total yield 5.9 per cent. of that theoretically capable of being formed from the dinitro-*o*-xylene employed. Although indications of the presence of the isomeric 4-nitro-*o*-3-xylydine were obtained, this substance has, as far as so far, been isolated in a pure condition.

3-Nitro-*o*-xylene from 3-Nitro-*o*-4-xylydine.

Two quantities of 5 grams of pure 3-nitro-*o*-4-xylydine were powdered and separately dissolved in a mixture of 30 c.c. of concentrated sulphuric acid and 5 c.c. of water, cooled in ice, and a solution of 2.1 grams of sodium nitrite in 10 c.c. of water gradually added, the temperature not being allowed to rise above 5°. The whole was then poured into 200 c.c. of boiling ethyl alcohol, heated for half an hour, the major portion of the alcohol evaporated, and the residue distilled in a current of steam, when an oil passed over readily. It was extracted with ether, washed with sodium hydroxide solution, then with water, dried over calcium chloride, and the ether evaporated, when 7 grams (theory 9 grams) of liquid were obtained, boiling constantly at 137–139°/29 mm.:

0.2017 gave 15.8 c.c. N_2 (moist) at 17° and 762 mm. $N = 9.11$

$C_8H_7O_2N$ requires $N = 9.27$ per cent.

PART I. 3-NITRO-O-XYLENE AND 3:6-DINITRO-O-XYLENE 2343

3-Nitro-*o*-xylene is a clear, pale yellow, refractive liquid boiling at 240°-760 mm., solidifying on cooling, and melting sharply at 15°. When dissolved in alcohol and the solution cooled in ice, it crystallises readily in radiating clusters of almost colourless, transparent needles.

A comparison of the properties of pure 3-nitro-*o*-xylene with those of the substance previously described is given in the following table, from which it is evident that the latter was not quite pure, although, considering its method of preparation, its comparative purity is rather remarkable.

	Source	B. p.	B. p.	M. p.
3-Nitro- <i>o</i> -xylene	Xylene + HNO ₃ + H ₂ SO ₄	245-246°/760 mm.	131°/20 mm.	7-9°
3-Nitro- <i>o</i> -xylene	3:4-Dinitro- <i>o</i> -xylene	240°/760 mm.	136°/20 mm.	15°

In order to obtain some idea of the amount of 4-nitro-*o*-xylene obtained in the 3-nitro-*o*-xylene prepared by the action of a mixture of nitric and sulphuric acids on *o*-xylene, the melting points of mixtures of 3-nitro-*o*-xylene with definite amounts of 4-nitro-*o*-xylene were determined.

3-Nitro- <i>o</i> -xylene, pure.....	Melting point.
" +1 per cent. of 4-nitro- <i>o</i> -xylene.....	15°
" +2 " " ".....	12-14°
" +5 " " ".....	11.5-13.5°
" +10 " " ".....	9-11°
" " " ".....	5-8°

From these figures it would appear that the 3-nitro-*o*-xylene prepared from *o*-xylene by the action of nitric and sulphuric acids contains about 7 per cent. of 4-nitro-*o*-xylene.

3:6-Dinitro-*o*-xylene.

The preparation of 3:6-dinitro-*o*-xylene by the nitration of nitro-*o*-xylene has been described (Trans., 1909, 95, 210), but as the substance was produced in such minute quantities the properties attributed to it were given with some reserve. Experiments with such larger quantities of material have now been carried out, and the substance has been obtained pure.

Attempts to prepare 3:6-dinitro-*o*-xylene by the elimination of the nitro-group in position 4 from 3:4:6-trinitro-*o*-xylene did not give the desired result (compare this vol., p. 2345), but it has now

been isolated in a pure condition by further nitrating 3:4-dinitro-*o*-xylene, and also from the residues obtained in the preparation of 3:4-dinitro-*o*-xylene (*ibid.*, p. 216), which residues contain about 0.3 to 0.5 per cent. of 3:6-dinitro-*o*-xylene.

Nitration of 3-Nitro-o-xylene.—Sixty grams of 3-nitro-*o*-xylene were nitrated and worked up as already described (*Trans.*, 1895, 214) to give the substance of a waxy nature, melting at 82–83° (1.1 grams), previously stated to be 3:6-dinitro-*o*-xylene. On further crystallisation from alcohol it gave a small amount of a substance melting sharply at 89–90°, which, as shown later, is the true melting point of 3:6-dinitro-*o*-xylene.

Nitration of o-Xylene.—It has been shown (*ibid.*, p. 216) that when *o*-xylene is nitrated with fuming nitric acid, there are produced 3:4-dinitro-*o*-xylene, 4:6-dinitro-*o*-xylene, a mixture of 4:5-dinitro-*o*-xylene and 3:4-dinitro-*o*-xylene of constant melting point, and a waxy solid of low melting point. It was thought from its nature that the latter substance would contain 3:6-dinitro-*o*-xylene, and such has been proved to be the case. To isolate it, 1250 grams of *o*-xylene were nitrated in quantities of 25 grams at one time, and the resulting solid worked up (*ibid.*, p. 212) for the separation of the dinitro-*o*-xylenes by alternate treatment with sulphuric acid and then alcohol, involving between five hundred and six hundred crystallisations from either sulphuric acid or alcohol. In this manner nearly 300 grams of the waxy solid of low melting point were obtained, which in quantities of 20 grams at one time were again submitted to fractional crystallisation from sulphuric acid and then alcohol (two hundred crystallisations), when 65 grams were obtained, melting at 50–60°. This latter substance was finally fractionated (one hundred crystallisations) from alcohol, when 3 grams of solid were obtained, melting sharply at 89–90°.

0.1355 gave 16.8 c.c. N_2 (moist) at 758 mm. and 20°. $N = 14.14$

$C_8H_6O_4N_2$ requires $N = 14.29$ per cent.

3:6-Dinitro-*o*-xylene is very soluble in the cold in the ordinary organic solvents, except alcohol, from which it crystallises in sheaves of small needles melting at 89–90°. It is not identical with any of the other three dinitro-*o*-xylenes, as proved by the following mixed melting-point determinations:

	M. p.		M. p.
3:6-Dinitro- <i>o</i> -xylene	89–90*	3:4-Dinitro- <i>o</i> -xylene	82
„	89–90	3:5-Dinitro- <i>o</i> -xylene	75
„	89–90	4:5-Dinitro- <i>o</i> -xylene	115

3:6-Dinitro-*o*-xylene should on further nitration yield only 3:4:6-trinitro-*o*-xylene, and not the isomeric 3:4:5-trinitro-*o*-xylene. In order to prove this point, 1 gram of pure 3:6-dinitro-

ylene was further nitrated by treatment with fuming nitric acid, and 1.2 grams (theory, 1.22 grams) of trinitro-*o*-xylene were

which after crystallisation from alcohol melted at 72°, and was any trace of the isomeric trinitro-*o*-xylene, melting at 115°, stated, although, as already shown, the separation of the two isomeric trinitro-*o*-xylenes is a very simple process.

CLIX.—*Derivatives of o-Xylene. Part II. Dinitro-o-xylidines.*

By ARTHUR WILLIAM CROSSLEY and GEORGE FRANCIS MORRELL.

THE experiments described in this communication originated with the desire to find a method for preparing 3:6 dinitro-*o*-xylene which would be less tedious and give larger yields than that described on p. 1313 of this volume.

In the first place, the action of reducing agents on 3:4:6-trinitro-*o*-xylene (I) was tried in the hope that it might be found possible to convert the nitro-group in position 4 into an amino-group, which could then be replaced by a hydrogen atom. Reduction with ammonium sulphide gave rise entirely to sulphur compounds, which were not further examined, and stannous chloride gave equally unsatisfactory results. Alcoholic ammonia, however, reduced 3:4:6-trinitro-*o*-xylene readily, but the nitro-group in position 3

VOL. XCIX.

was the one to be attacked, and there resulted 4:6-dinitro-*o*-4-xylydine (II), which is proved by the fact that when the dinitroamine is diazotised and the diazo-group replaced by a hydrogen atom, 4:6-(3:5)-dinitro-*o*-xylene (III) is produced. The nitro-*o*-xylenes mentioned in this communication were described in the *Transactions* 1909, 95, 202.

The next attempt consisted in nitrating 3-nitroaceto-*o*-4-xylydine (VI), which was prepared by acetylating 3-nitro-*o*-4-xylydine (V), obtained by the reduction of 3:4-dinitro-*o*-xylene (IV) with stannous chloride, but the nitro-group, instead of entering position 1 as was thought possible, takes up position 5, giving 3:5-dinitroaceto-*o*-4-xylydine (VII). The constitution of this substance was deter-

mined by removal of the acetylaminogroup, when 3:5-dinitro-*o*-xylene (IX) is obtained. 3:5-Dinitro-*o*-4-xylydine is also produced by the reduction of 3:4:5-trinitro-*o*-xylene (X) with acid ammonia.

Having proceeded so far, it seemed of interest to attempt the preparation of all the six possible dinitro-*o*-xylydines which on theoretical grounds should exist. Five of them are now described, the missing 3:6-dinitro-*o*-4-xylydine (XI) being the one which it was desired to prepare for the initial object of this research. In the reactions which have been tried, wherever it was possible for two different dinitroamines to result, evidence was forthcoming to show that both isomerides were formed, although one of the two was always obtained in largely predominating amount. It is therefore quite possible that 3:6-dinitro-*o*-4-xylydine is produced in some of these reactions, but under the conditions tried the amount must have been extremely small, and its isolation for all practical purposes an impossibility.

The next series of reactions consisted in nitrating aceto-*o*-xylylide (XII) under varying conditions, and the results are readily followed on consulting the accompanying diagram :

The product with fuming nitric acid alone, after elimination of the acetyl group, is identical with the substance obtained by the action of alcoholic ammonia on 3:4:5-trinitro-*o*-xylene, and is therefore 3:5-dinitro-*o*-4-xylylidine.

A mixture of nitric and sulphuric acids gives a new dinitroamine, in which the position of the nitro-groups was ascertained by elimination of the amino-group, when 5:6-(3:4)-dinitro-*o*-xylene resulted. The dinitroamine is therefore 5:6-dinitro-*o*-4-xylylidine, which can also be prepared from aceto-*o*-xylylide by first treating it with a mixture of 70 per cent. nitric acid and sulphuric acid, and nitrating the resulting 6-nitroaceto-*o*-4-xylylide with fuming nitric acid (compare Noeling, Braun, and Thesmar, *Ber.*, 1901, **34**, 2251).

Two other dinitro-*o*-xylylidines were obtained by nitrating 5-nitro-

aceto-*o*-3-xylylide, involving the series of reactions indicated by the following formulae:

With fuming nitric acid 4:5-dinitro-*o*-3-xylylide is formed, as proved by the fact that removal of the amino-group gives rise to 4:5-dinitro-*o*-xylene, whereas 5:6-dinitro-*o*-3-xylylide results from the action of a mixture of nitric and sulphuric acids. This dinitroamine was not converted into a dinitro-*o*-xylene, for as only 5-nitro-*o*-3-xylylide can result from the nitration of 5-nitro-*o*-3-xylylide and the constitution of one of the two has been decided, no doubt can exist as to the position of the nitro-groups in the second product of nitration.

EXPERIMENTAL.

Reduction of 3:4:6-Trinitro-o-xylene.

3:4:6-Trinitro-*o*-xylene in quantities of 10 grams at one time was suspended in 100 grams of absolute alcohol, and dry ammonia passed in until the solution was saturated. The liquid first turned blue, then deep purple, changing to deep red as the trinitro-*o*-xylene passed into solution. The whole was allowed to remain for twenty-four hours, when a bronze-green, crystalline solid (7 grams) had separated. This was collected, and extracted with boiling alcohol when 5.2 grams of fine, yellow needles were obtained. The insoluble residue was not further examined:

0.1909 gave 0.3208 CO_2 and 0.0720 H_2O . $\text{C} = 45.73$; $\text{H} = 4.19$.

0.1188 " 20.3 c.c. N_2 (moist) at 20° and 757 mm. $\text{N} = 19.6$.

$\text{C}_8\text{H}_9\text{O}_4\text{N}_3$ requires $\text{C} = 45.50$; $\text{H} = 4.26$; $\text{N} = 19.90$ per cent.

4:6-Dinitro-o-3-xylylidine is readily soluble in cold acetone or on warming in ethyl acetate, chloroform, or benzene, and crystallises from alcohol in fine, golden-yellow needles, melting at 161°.

The *diacetyl* derivative, prepared by heating the amine with a mixture of equal parts of acetyl chloride and acetic anhydride on the water-bath for three hours, is readily soluble in the cold in chloroform, readily on warming in benzene, ethyl acetate, or acetone, and crystallises from alcohol in large, transparent, fern-like aggregates, melting at 139°:

0.741 gave 21.2 c.c. N_2 (moist) at 15° and 758 mm. $N=14.22$.

$C_{12}H_{13}O_6N_3$ requires $N=14.24$ per cent.

To determine the number of acetyl groups, the substance was hydrolysed with alcoholic potassium hydroxide, the alcohol evaporated, the residue acidified with sulphuric acid, distilled in a current of steam, and the acetic acid titrated with $N/10$ -sodium hydroxide solution:

0.8113 required 0.232 gram NaOH. $CH_3 \cdot CO=29.6$.

$C_{12}H_{13}O_6N_3(CH_3 \cdot CO)_2$ requires $CH_3 \cdot CO=29.1$ per cent.

Conversion of 4:6-Dinitro-o-3-xylylidine into 4:6-Dinitro-o-xylene.

Four grams of 4:6-dinitro-o-3-xylylidine were dissolved in a mixture of 2.4 c.c. of concentrated sulphuric acid and 4 c.c. of water, the mixture cooled in a freezing mixture, and the calculated quantity of 10 per cent. solution of sodium nitrite gradually added (compare Banksma, *Rec. trav. chim.*, 1909, **28**, 93). The whole was then poured into 100 c.c. of boiling ethyl alcohol, heated for thirty minutes, poured into water, and the precipitated solid crystallised from alcohol, when it melted at 75°; nor was this melting point altered on mixing with pure 4:6-dinitro-o-xylene:

0.9011 gave 12.6 c.c. N_2 (moist) at 18° and 761 mm. $N=14.40$.

$C_8H_6O_4N_2$ requires $N=14.29$ per cent.

Reduction of 3:4:5-Trinitro-o-xylene.

Ten grams of 3:4:5-trinitro-o-xylene were reduced with alcoholic ammonia as described in the case of the isomeric trinitroxylenes (p. 2318), when 8.8 grams of crude material were obtained. No part of the reduction product was insoluble in alcohol:

0.1100 gave 18.8 c.c. N_2 (moist) at 20° and 768 mm. $N=19.76$.

$C_8H_9O_4N_3$ requires $N=19.9$ per cent.

3:5-Dinitro-*o*-4-xylydine is readily soluble in the cold in chloroform, benzene, or ethyl acetate, and crystallises from ethyl alcohol in orange-red needles, melting at 143°.

The acetyl derivative, prepared by heating the nitroamine with a mixture of equal parts of acetic anhydride and acetic acid, crystallises from alcohol in transparent needles, melting at 223°.

0.1204 gave 16.8 c.c. N_2 (moist) at 19° and 768 mm. $N = 16.7\%$

$C_{10}H_{11}O_5N_3$ requires $N = 16.6$ per cent.

The conversion of 3:5-dinitro-*o*-4-xylydine into 3:5-dinitro-*o*-xylylene was carried out exactly as described in the case of 4:6-dinitro-*o*-3-xylydine (see p. 2349). The resulting substance crystallised from alcohol in needles, melting at 75°, nor was this melting point altered on admixture with pure 3:5-dinitro-*o*-xylylene.

*Nitration of 3-Nitroaceto-*o*-4-xylylide.*

3-Nitroaceto-*o*-4-xylylide was prepared by reducing 3:4-dinitro-*o*-xylene with stannous chloride (compare this vol., p. 2342), and heating 2 grams of the resulting 3-nitro-*o*-4-xylydine with acetyl chloride for two hours. If the heating with acetyl chloride was continued for a longer period, a product of higher melting point, probably a diacetyl derivative, is produced. The excess of acetyl chloride was then evaporated, and the resulting viscid solid triturated with cold ethyl alcohol, when 2 grams of a clear, white solid were obtained, which crystallised from alcohol in stout, transparent needles, melting at 115° (compare Noetting, Braun, and Thesmar-Ber., 1901, 34, 2251).

One gram of 3-nitroaceto-*o*-4-xylylide was dissolved in 5 c.c. of concentrated sulphuric acid, cooled in a freezing mixture, and 15 c.c. of a mixture of one part of nitric acid (D 1.42) and two parts of concentrated sulphuric acid added, so that the temperature remained below -3°. The whole was allowed to remain at this temperature for two hours, poured on ice, filtered, the residue washed with a little ether, and crystallised from alcohol, when 9.4 grams of pure 3:5-dinitroaceto-*o*-4-xylylide were obtained.

The nitration was also carried out with fuming nitric acid and sulphuric acid, and also with nitric acid (D 1.5 and 1.42) alone; the former gave rise to the same dinitroaceto-*o*-xylylide, but in smaller yield, and with nitric acid only resinous products were obtained.

*Nitration of Aceto-*o*-4-xylylide.*

(a) *With Fuming Nitric Acid.*—One gram of aceto-*o*-4-xylylide was gradually added to 10 c.c. of fuming nitric acid, the temperature being maintained below -5°. The whole was poured on ice

and the precipitated solid (1.1 grams) crystallised from alcohol, then pure 3:5-dinitroaceto-o-4-xylylide, melting at 223°, was obtained.

(A) *With Fuming Nitric Acid and Sulphuric Acid.*—Five grams of aceto-o-4-xylylide were dissolved in 30 c.c. of concentrated sulphuric acid, cooled in a freezing mixture, and 45 c.c. of a mixture of one volume of nitric acid (D 1.5) and two volumes of sulphuric acid gradually added. The whole was poured on ice, the solid collected and crystallised from alcohol, when 5.1 grams of a substance melting at 170–171° were obtained:

0.1030 gave 14.8 c.c. N_2 (moist) at 20° and 754 mm. $N=16.30$.
 $C_{10}H_{11}O_3N_3$ requires $N=16.60$ per cent.

5.6(3:4). *Dinitroaceto-o-4-xylylide* crystallises from alcohol in fine, white needles melting at 173°. It was saponified by heating to 200° with ten times its weight of concentrated sulphuric acid for ten minutes, poured on ice, and the precipitate crystallised from alcohol:

0.1036 gave 18.2 c.c. N_2 (moist) at 22° and 753 mm. $N=19.72$.
 $C_8H_9O_4N_3$ requires $N=19.9$ per cent.

5.6(3:4). *Dinitro-o-4-xylylidine* is only very moderately soluble in ethyl alcohol, benzene, or chloroform, and crystallises from acetone in deep orange-red needles, melting at 212°. When the amino-group was removed from this dinitroamine by the process described on p. 2349, it gave 3:4-dinitro-o-xylene, melting at 82°.

(A) *With Nitric Acid (D 1.42) and Sulphuric Acid.*—When aceto-xylylide was nitrated by adding to its solution in concentrated sulphuric acid a mixture of nitric acid (D 1.42) and concentrated sulphuric acid, it gave 6(3)-nitroaceto-o-4-xylylide, melting at 210°, and previously described by Noelting. The latter substance on treatment with fuming nitric acid was converted in good yield into 6(3:4)-dinitroaceto-o-4-xylylide, melting at 173°.

Nitration of 5-Nitroaceto-o-3-xylylide.

(a) *With Fuming Nitric Acid.*—5-Nitro-o-3-xylylidine (m. p. 111°) was prepared by reducing 3:5-dinitro-o-xylene with stannous chloride (compare this vol., p. 2342). The acetyl derivative melting at 230° (compare Noelting, Braun, and Thesmar, *Ber.*, 1901, **34**, 2047) is best prepared by dissolving the amine in five times its weight of benzene, adding a solution of acetic anhydride (in amount equal to that of the amine taken) in benzene, warming for a minute or two, when the whole becomes semi-solid, and crystallising the solid from alcohol. Twenty-four c.c. of fuming nitric acid were gradually added to 2 grams of 5-nitroaceto-o-3-xylylide surrounded by a freezing mixture, the whole allowed to remain for one and

a-half to two hours at 8–10°, poured into ice-water, the precipitate washed with a little ether, and crystallised from alcohol:

0.1048 gave 15.2 c.c. N_2 (moist) at 22° and 767 mm. $N=16.6$ per cent.
 $C_{10}H_{11}O_5N_3$ requires $N=16.6$ per cent.

4:5-Dinitroaceto-o-3-xylylide is very readily soluble in acetone and ethyl acetate, moderately so in hot alcohol or benzene and crystallises from alcohol in colourless needles, melting at 225°. It was hydrolysed by heating to 90° for five minutes with ten times its weight of concentrated sulphuric acid, poured into water, and the precipitate crystallised from alcohol:

0.1010 gave 17.3 c.c. N_2 (moist) at 20° and 769 mm. $N=19.9$ per cent.
 $C_8H_7O_4N_3$ requires $N=19.9$ per cent.

4:5-Dinitro-o-3-xylydine is readily soluble in the cold in acetone or ethyl acetate, readily so on warming in benzene or chloroform, and crystallises from alcohol in radiating clusters of orange needles, melting at 143°. On removal of the amino-group by the method already indicated, 4:5-dinitro-o-xylene, melting at 115°, was obtained.

(b) With Fuming Nitric Acid and Sulphuric Acid.—Six grams of 5-nitroaceto-o-3-xylylide were dissolved in 30 c.c. of concentrated sulphuric acid, and 90 c.c. of a mixture of one volume of fuming nitric acid and two volumes of sulphuric acid gradually added, allowed to remain at 8–10° for two hours, poured on ice, and the precipitate crystallised from a mixture of four parts of benzene to one part of acetone:

0.1012 gave 14.8 c.c. N_2 (moist) at 24° and 758 mm. $N=16.6$ per cent.
 $C_{10}H_{11}O_5N_3$ requires $N=16.6$ per cent.

5:6-Dinitroaceto-o-3-xylylide is readily soluble in alcohol, acetone or ethyl acetate, and crystallises from the above-mentioned mixture of solvents in white plates, melting at 180°. It was hydrolysed by heating with ten times its weight of concentrated sulphuric acid for twenty minutes at 110–115°, and the product crystallised from alcohol and analysed:

0.1114 gave 19.7 c.c. N_2 (moist) at 24° and 756 mm. $N=19.7$ per cent.
 $C_8H_6O_4N_3$ requires $N=19.90$ per cent.

5:6-Dinitro-o-3-xylydine is readily soluble in the cold in acetone, acetate or acetone, and crystallises from alcohol in deep yellow needles, melting at 172°. It is soluble in concentrated hydrochloric acid to form a colourless solution, which deposits tabular crystals of a very unstable hydrochloride. This is the only dinitro-o-xylyl compound described in this communication which shows any tendency to form salts.

BERTHELOT MEMORIAL LECTURE.

DELIVERED ON NOVEMBER 23RD, 1911.

By HAROLD BAILY DIXON, M.A., Ph.D., F.R.S., Past-President
of the Chemical Society.(1) *His Career.*

In this age of extreme specialisation, the life and work of Berthelot teach the world the much-needed lesson that men of science are not necessarily men of one idea, but may be great, not only as experimenters, but great also as thinkers and as citizens. On all that he turned his mind to—and few things were foreign to his interest—Berthelot brought to bear, not only an exact scientific method and an exquisite clearness of statement, but an imagination as far-reaching as it was comprehensive, a patriotism as pure as it was enlightened. In the work of his life—whether as a philosopher or as a Cabinet Minister—Berthelot looked to Science as his guide. He believed in science as an illuminating and humanising force; he believed that in science lay the secret of the progress of France and of mankind. To pursue science was to ensure progress; science was to him a mission, a recreation, a religion. "To the end of my life" he wrote half-sadly to Renan (in 1892), "I shall be the dupe of this desire for progress which you so wisely relegate to the sphere of illusions." But of the reality of the progress achieved by Berthelot no chemist can doubt. In the realm of industry alone what tempting offers were made to him for a monopoly of his synthetic processes in organic chemistry. But Berthelot never bargained with or patented his discoveries. "The man of science," he declared, "should make the possession of Truth his only riches." So that Berthelot considered the applications of science beneath him; on the contrary, he believed that science should be pursued simply by reason of its service to mankind. "Science has a double aim," he wrote, "an ideal aim which is the search for pure truth, and a positive and human aim which is the good of man and the development of civilisation."

Pierre Eugène Marcellin Berthelot* was born in the heart of the old Paris, in the Place de Grève—now Haussmannised out of recognition into the Place de l'Hôtel de Ville—on October 25th, 1827.

* I am indebted to the kindness of Berthelot's son—Prof. Daniel Berthelot—for numerous dates, and also for much other valuable information. I desire also to express my obligation to my old student, Mr. A. S. Robinson, for making me a perusal of Berthelot's papers.

He died in Paris, March 18th, 1907. As he was born and bred so he lived and died a Parisian.

Through his father, Dr. Jacques Martin Berthelot, the son inherited his scrupulous regard for duty, his serious love for science, his liberal instincts, and his philosophic outlook on life. Through his mother, Ernestine Sophie Claudine Béard, he inherited his ardent and responsive nature, his amazing industry, his versatility, and his curiosity. From the Place de Grève his family moved to a house near by in the narrow Rue des Ecrivains, just opposite the Tour Sainte-Jacques. The somewhat delicate and high-strung boy grew up in sight of those royal ceremonials—the Corpus Christi processions from the Tuileries to Notre Dame—when people in the street were obliged to kneel, under penalty of sacrilege, as the procession passed. As a child the roar of the revolution may have sounded in his ears, for his father's house overlooked a scene of many of those deeds of violence that marked the popular upheaval against the Ordinances of the 25th of July (1830). Then, as again in the later revolutions, the house became a headquarters equally for Royalist and for Republican, for Dr. Berthelot made no distinction between his patients, however much his sympathy went out to the suffering people.

Even from the age of ten, Berthelot tells us, he began to ponder on the problems of life, and was troubled by the insecurity of the future. Nevertheless, he was an industrious and brilliant scholar and made rapid progress at the school he attended—the Collège Henri IV. Sixty years later at the Jubilee Celebration, M. Fournet, the President of the Académie des Sciences, bore striking testimony to Berthelot's gifts as a boy. "Everyone admires in you your power of work, your spirit of invention, your logic of ideas, your grasp of memory, your skill in experiment. . . . I affirm that these precious gifts you already possessed in the germ when you were still a simple schoolboy. More than half a century ago we sat side by side on the benches of the mathematical class in the Collège Henri IV.; a close comradeship grew up between us. My recollections bring back with pleasure the long talks we had on every kind of question. . . . I still see myself in discussion with you on the muddy road that led to your house at the foot of the Tower of Saint-Jacques. There I met the kindest greeting from your father, and then we climbed to your attic and resumed our interrupted argument—our only distraction being the swallows that darted among the sculptures of the old tower."

At the end of his school course in 1846 he took the highest rank in competition with all the best students from the lycées of Paris.

the "prix d'honneur de philosophie." To his sound classical education he attached great value, and his love of ancient literature lasted through life. Two old editions of Lucretius and of Tacitus, preserved from his schooldays, were his constant companions when he left Paris. He quoted Horace familiarly, and he has told us that he soon recovered his Greek when he began to decipher the Alexandrine MSS. on Alchemy.

His school studies over, he made up his mind to pursue natural science as a career, and he even mapped out a programme for the methodical study of the principles of *all* branches of science in what he afterwards called the "naïve confidence of youth." But, whatever much he may have had to curtail his educational ambition, he completed during the next few years a full medical course, he studied chemistry in the laboratory of Pelouze, and passed the university examinations for Bachelier and Licencié-ès-Sciences. To carry out this programme he took a small lodging in the Rue de l'École-de-Médecine, and attended the school of M. Crouzet. In this school happened that fortunate meeting between Berthelot and Renan—the beginning of a friendship which became from that day a principal element in the lives of both. Renan, then twenty-two, had renounced his clerical orders, and retired from the school of Sulpice. Lonely and depressed by his mental struggles, he had become an assistant master in the school, but could not shake off his melancholy. Berthelot spoke to him, the talk became intimate, something in each ardent nature was touched and responded, and the two were drawn together until soul reacted on soul like acid and alkali. "Our friendship," wrote Renan, "was something analogous to that of the two eyes when they fix upon the same object, and from the two images there results a single impression in the brain." Renan and Berthelot would take long walks together, and on Sundays would visit Neuilly, then in the country, where Berthelot's parents had taken a house, and there they discussed the eternal problems that torture the human mind. One day Renan called his young friend a "Revolutionist." But Berthelot had one sure faith, built on the ruins of other beliefs. "I a Revolutionist?" he cried, "clear your mind of that notion; call me rather an 'Evolutionist.'" We must remember that this was said a decade before Darwin gave us the "Origin of Species."

The ideas resulting from their stimulating intercourse took different shapes in the two minds, and though Renan admitted his indebtedness to Berthelot, it is impossible for us, as it was for them, to separate what was due to each. On the monument of Berthelot

which is to be placed in the Gardens of the Luxembourg, the sculptor, Saint Marceau, has introduced the face of Renard, a memorial of one of the most notable friendships of our time.

Under Pelouze the experimental skill of the young chemist rapidly developed, and in 1850 he presented his first paper to the Academy of Sciences—"On a simple method of demonstrating the liquefaction of gases." He showed how the gases chlorine, ammonia, and carbon dioxide could be liquefied in the capillary end of a glass tube by the expansion of mercury filling the body of the tube. When oxygen and nitric oxide showed no sign of liquefaction under pressures of 700 to 800 atmospheres he rightly concluded that under certain conditions of temperature it was not possible to liquefy gases by pressure alone. A second paper appeared the same year, and in January, 1851, Berthelot received the appointment, that of lecture-assistant to Balard, the discoverer of bromine, then Professor of Chemistry in the Collège de France. Unluckily the stipend was not a living wage—800 francs (£124 a year)—and to earn a living Berthelot had to give private lectures. Luckily the official duties of the post were not heavy, and the resources of the laboratory were placed freely at his disposal. Balard, who in proposing him for the post wrote: "Everything allows us to hope that M. Berthelot will know how to utilize for the advancement of science the position I ask for him." In the years from his appointment Berthelot had obtained his degree by his remarkable thesis, "On the combinations of glycerine with acids, and on the synthesis of the immediate principles of fats." A year later he began to publish his work on the synthesis, and the same year (1855) made the memorable syntheses of ethyl alcohol from ethylene, and of formic acid from carbon monoxide, which revolutionised the accepted ideas on the formation of organic compounds. Then followed in quick succession researches on the synthesis of hydrocarbons, of methyl alcohol, and of oxalic acid. After eight years' brilliant work, Berthelot was appointed Professor in the Ecole Supérieure de Pharmacie, where he lectured, but continued to act as assistant and to research in the Collège de France. This was the first public recognition of his discoveries. Early in the following year (1860) this Society honoured itself by electing him a Foreign Member. At the invitation of Alexander Williamson, then President, Berthelot lectured before the Chemical Society "On the synthesis of organic substances" on June 4th, 1863. It is pleasant to think that our Chemical Society led, rather than followed, the fashion.

With the appearance of his first book, "Organic Chemistry founded on Synthesis" (1860), the fame of Berthelot quickly spread.

The Jockey Prize was awarded to him in 1861 by the Academy of Sciences. The professors of the Collège de France, headed by Berthelot, petitioned the Minister of Public Instruction to found a chair for Berthelot, and this movement resulted in his being appointed to a Professorship in the College in 1861, and finally (in August, 1865) in the formation of a special Chair of Organic Chemistry, which Berthelot held until his death. But though his academic promotion was slow, honours came thickly to him in his middle age. The French Academy of Medicine elected him a member in 1863; he was elected to the Academy of Sciences in 1865, and of this body he succeeded Pasteur as Perpetual Secretary in 1899. In 1900 he became one of the forty French Academicians. I cannot attempt any enumeration of the various learned societies to which he became an honorary fellow; I will only mention that he was elected a foreign fellow of our Royal Society in 1877, and that a Davy Medal was awarded in duplicate to him and to his friendly rival in thermochemistry, Julius Thomsen, in 1883, and that he received the Copley Medal, the highest distinction the Royal Society has to bestow, in 1900.

On his appointment to a Professorship in the Collège de France, Berthelot was enabled to fulfil his engagement to Mademoiselle Caroline Niaudet, niece of M. Louis Breguet, a Frenchman whose family had been prosperous manufacturers of scientific instruments for many years, and who himself was the constructor of the well-known telegraph and induction coil. The story goes that the Berthelot and Breguet families had been intimate for some years, but Marcelin had not lifted his eyes to the beautiful Mademoiselle Sophie until one day accident brought them into contact on the Pont-Neuf. She was crossing the long bridge in front of Berthelot, and making her way with difficulty in the teeth of a strong wind, when a stronger gust catching her skirt and her hat blew Mademoiselle round into the arms of her future husband.

They were married on May 10th, 1861. Never was a happier match, or a more devoted family than Berthelot's. Madame Berthelot was endowed above most women with grace, with tact, and with sympathy; she brought into his life that great gift of serenity which Berthelot regretted he had not inherited from his mother. Well might he have appreciated our homely English saying, "It's a good wind that blows nobody any good."

Busy in his laboratory by day and in his study by night, Berthelot took little part in public life under the imperial régime until the overthrow of Louis Napoleon and the siege of Paris in 1870. Then he threw himself whole-heartedly into the work of resisting the

invaders, and as president of the Scientific Committee of National Defence superintended the manufacture of explosives to be used against the enemy. After the war Berthelot continued the study of explosives, to which he applied all his experimental skill and the knowledge he had acquired in his thermochemical researches. In collaboration with Vieille he began a systematic investigation of the phenomena of explosions, which finally resulted, not only in the invention of a powder that gave to French arms for some years a remarkable superiority, but in the addition to science of a new chemical constant—*l'onde explosive*.

His work on the combination of nitrogen with organic bodies under the influence of the silent electric discharge turned his attention to the fixation of nitrogen by plants in the soil. In 1882 a laboratory was built for him on the heights of Meudon, and here he devoted himself every summer to problems of vegetable chemistry.

Determined to take his share in the government of his country, he was elected a Permanent Senator in 1881, and in 1886 became Minister of Public Instruction in the Cabinet of M. Goblet. Here he found the opportunity of impressing on his generation his strong convictions on the educative and liberalising power of science. But he was no advocate of an illiterate mechanical training; he held firmly that science should be taught on the wide basis of a literary culture. It was in this spirit that he met the demand for "technical education" which swept over Europe. Industry demands two things, according to Berthelot: capable directors and competent workers. To be capable the director must be a judge of men and a judge of things; he must be trained in literature, history, and science; the high school and the university will prepare him for his business. To be competent the worker must be intelligent and skilful; the elementary school and the workshop will fit him for his job. Berthelot saw no need for ordinary technical schools—except as evening schools to help the workman. Can we yet say that Berthelot was wrong? At all events, he knew what he wanted, and he helped France to get it.

In 1895 Berthelot accepted the Portfolio of Foreign Affairs in the Bourgeois Cabinet. In this difficult post he had to negotiate the Anglo-French treaty dealing with the status and boundaries of Siam, which found herself in the uncomfortable position of "buffer" state between the French in Annam and the English in Burma. Berthelot did not feel the duties of the Foreign Office congenial, and he resigned shortly after signing the treaty with Great Britain. But this, I think, we can say—that as a politician he had a sincere regard for England, and had he continued to guide the foreign relations of France the *Entente*, that has happily smoothed away

so many difficulties between the two nations, might have blossomed a decade earlier.

That Berthelot was a man of peace is evident from his book, "Science et Libre Pensée." It contains a strong plea for international arbitration. Of his other books mention must be made of his studies of the Greek and Arabian alchemistic writings. In 1869 Berthelot visited Egypt, where his imagination was struck with the early records of chemical and metallurgical experiments and ideas. He returned to this subject later, and followed it up with his characteristic eagerness. By his influence he obtained the reproduction of many rare manuscripts on alchemy, which he edited in collaboration with M. Kuelle, "Collection des Alchimistes Grecs," and with MM. Duval and Houdas, "La Chimie au Moyen-Age."

Few more interesting chemical papers have ever been published than the hundred and one preparations and recipes comprised in the papyrus of Leyden translated by Berthelot. They reveal some of the methods of the Egyptian priesthood, who were the holders of the secrets of chemistry. How pitifully is described the conversion of a copper vessel into a beautiful vase of gold (by rubbing it with gold amalgam and heating)—a vase which will stand the regular test of the touch-stone! With what cynical pleasure Berthelot remarks that such a fraud was no doubt quite natural, and even commendable in the eyes of a priest!

In 1880 it was my great privilege to be introduced to Berthelot in his laboratory at the Collège de France by Sainte-Claire Deville and Alexander Williamson. I had just been showing for the first time non-explosive mixtures of dried carbon monoxide and oxygen at the British Association Meeting at Swansea. Deville was enthusiastic over the discovery, since it upset one of our cherished ideas; but Berthelot was more philosophical. Carbon monoxide was a gas, he said, "a little capricious" in its ways. One must repeat and again repeat such experiments. Most sound advice! I had, by the way, been repeating these experiments for four years before I published them; and it was in "again repeating" them that, all unconsciously, I struck across one line of Berthelot's own work—the measurement of the rate of explosion in gases.

But except for this natural attitude of philosophic doubt Berthelot was kindness itself. We were taken to his home in the institute, and were entertained by Madame Berthelot, whose silver hair heightened the saint-like beauty of her face. Berthelot was full of fire and quick replies. When Williamson rallied him on the rapidity with which his memoirs appeared, Berthelot replied, "Ah! you English are too cautious, too frightened of committing your-

selves; what is worth doing is worth publishing!" It was perhaps characteristic of him that an hour before he had given me the opposite and better advice.

Those who met Berthelot in his prime could not but be struck with the intellectual sincerity and the intense enthusiasm of the man. The broad forehead, the brilliant, blue eyes, the clear features, and the thoughtful expression impressed all who saw him, while his musical voice and clear enunciation charmed the ear. It would be impossible to forget that first impression.

Students who attended his lectures speak in the highest terms of the inspiration they drew from his teaching. He gave of his best, and delighted to show his audience the new experiments he was engaged upon. But it was when he forgot the immediate experiment in hand, and began to think aloud, that the inspiration was highest. Here truly was science "in the making."

(2) *His Scientific Work.*

In considering the amazing output of scientific work we owe to Berthelot, it would be useless to enumerate, and hopeless to discuss individual memoirs. Luckily they can be grouped into well-marked divisions, for Berthelot always followed up a train of thought until some logical explanation was reached that satisfied his mind. The some idea suggested by the first research was followed up experimentally until another generalisation was reached, and other trains of thought could be pursued.

Study of Glycerine.—As soon as he was installed in Berthelot's laboratory in the Collège de France, Berthelot took up a line of research which led him on to discoveries of the highest interest. He began to study the modes of combination of glycerine with acids and proved that it was an alcohol capable of combining with acids to form "etherial salts"—thus bearing out the views of Chevreul that fats were "compound ethers," and justifying the modern name "glycerol"; but he also showed that glycerol differed from ordinary alcohol by its ability to combine with three equivalents of an acid instead of with one, just as phosphoric acid differs from nitric acid in combining with three equivalents of a base. By what seems a curious mental slip Berthelot likened the three classes of esters formed by glycerol to ortho-, para-, and meta-phosphates, instead of to their true analogues, the three salts of ortho-phosphoric acid. Wurtz not only made the correction, but by his synthesis of glycol—the "diatomic" intermediate between the "monatomic" alcohol and the "triatomic" glycerol—confirmed the importance of Berthelot's discovery. The work of Berthelot and Wurtz on the

alcoholic alcohols must rank in importance with that of Liebig in the organic polybasic acids. I think, also, it is clear that the analogies shown by alcohols to inorganic bases—and I may specially mention the analogy between glycerol and bismuth hydroxide pointed out by Odling—led to the general adoption of the idea of agency which had been given to chemistry by Edward Frankland. The proof that glycerol is an alcohol led Berthelot to prepare and examine many other bodies of a like nature. We are indebted to Berthelot for a considerable number on the list of substances recognised as alcohols, and we constantly employ his method of saponification as the means of recognition.

Synthesis of Organic Substances.—I can only make a passing mention of very few of the many compounds of glycerol prepared by Berthelot by submitting it to the action of acids. Hydriodic acid, he found, yielded two substances, isopropyl iodide and allyl iodide; from the latter he made for the first time artificial oil of mustard.

The curious reducing power of hydriodic acid, especially at a high temperature, he afterwards made good use of in reducing benzene-hexane-derivatives (1867). But the most stimulating thing to Berthelot's mind was the discovery that glycerol would combine, if we were given it, with all sorts of different acids, producing new bodies, and that one could predict the formation of an endless number of new substances through a "creative power greater than as realised in nature." This idea, once planted in his mind, was apace. He sought and found methods for preparing the simpler types of organic compounds, and from these to pass on to the higher and more complicated. To appreciate the boldness of Berthelot's conceptions we must remember the firm conviction of chemists held throughout the first half of the last century, that there was a gulf fixed between inorganic and organic substances; a chemist might build up, or synthesise, inorganic salts, but he could only break down, or analyse, the substances created in plants and animals by the "vital force." This gulf had not been really closed in the eyes of most chemists by the synthesis of urea by Wöhler or the formation of acetic and propionic acids from their esters by Kolbe and Frankland, for the cyanides from which these substances were formed were regarded as organic products themselves.

Berthelot's first success on his new path came in 1855. He shook pure sulphuric acid in a large globe holding 32 litres of ethylene until 30 litres of the gas had been absorbed. The liquid was mixed with water and distilled. The liquid coming over was red and redistilled until 45 grams of a liquid having all the

properties of pure alcohol were obtained. But the original ethylene had itself been obtained from alcohol—so the synthesis might be said to be contaminated at its source. Berthelot next prepared ethylene iodide from coal gas, and from this prepared a sample of ethylene, which he treated as before. It yielded alcohol, which was thus made for the first time without fermentation.

Now since ethyl alcohol on heating with sulphuric acid yields ethylene and water, and formic acid on heating with sulphuric acid yields carbon monoxide and water, if the first process could be reversed, it might be predicted that the second would also:

Berthelot placed 10 grams of potash in a half-litre flask, which he filled with carbon monoxide, sealed, and heated for three days in a water-bath. When the flask was opened under mercury the gas was found to be completely absorbed; on dissolving the potash salt in dilute sulphuric acid and distilling, Berthelot obtained a distillate of formic acid.

In the following year (1856) a more difficult synthesis was effected—that of marsh gas, together with ethylene and acetylene. Formic acid on heating yields all its carbon as carbon monoxide and its hydrogen as water; but if there is present a strong base, which might cling to some of the carbon, a substance containing carbon and hydrogen might be evolved. Berthelot prepared formic acid on a large scale from carbon monoxide, combined it with baryta and distilled the barium formate at a red heat. He condensed a small amount of liquid, caught the unsaturated hydrocarbons in bromine, and collected the marsh gas over water. The unsaturated hydrocarbons were ethylene and propylene. On decomposing the bromides by means of water and copper foil in thick glass tubes at 275°, Berthelot regenerated the ethylene and propylene and found about 10 per cent. of acetylene—the result of a secondary action. From this ethylene he again prepared pure alcohol.

Berthelot's next starting point was carbon disulphide. If carbon disulphide were heated with a metal capable of combining with sulphur, while at the same time hydrogen were liberated in contact with the nascent carbon, the two might combine to form a hydrocarbon. Passing hydrogen sulphide and carbon disulphide vapour through a broad tube packed with copper turnings freshly reduced and heated to a dull red heat, Berthelot condensed a trace of naphthalene, and collected ethylene in bromine and marsh gas over water. Iron acted in the same way as copper, and hydrogen phosphide and steam could be used instead of hydrogen sulphide.

Berthelot regenerated the ethylene as before (finding acetylene produced), and prepared alcohol from it. One cannot help feeling in reading Berthelot's account of this experiment that in his mind the ethylene (with its resulting alcohol) was more important than the marsh gas. But a year later Berthelot chlorinated marsh gas in diffused daylight, separated the methyl chloride from the residual marsh gas and higher chlorides by solution in anhydrous acetic acid, and prepared methyl alcohol from the chloride.

Just as Berthelot had got ethyl alcohol from ethylene and sulphuric acid, so he obtained propyl alcohol from propylene and sulphuric acid. The propylene was prepared from the propyl chloride obtained from glycerol and phosphorus iodide. Again he showed that the higher olefines could be combined with hydrogen chloride and the chlorides turned into the corresponding alcohols--a general method by which he prepared many alcohols; and *vice versa*, by abstracting the elements of water the olefines could be prepared from the alcohols. Again, as barium formate yielded on distillation several hydrocarbons, so might the acetate of sodium yield other hydrocarbons than marsh gas. Berthelot found that it yielded higher olefines as well, namely, propylene, butylene, and styrene.

But among the most memorable of Berthelot's syntheses was the direct combination of hydrogen and carbon in the electric arc to form acetylene (1862), and the condensation of acetylene into benzene (1866); thus the barrier between inorganic and organic chemistry was broken down at all points, and Berthelot's disciples could exclaim with justice: "There is but one chemistry, and Berthelot is its prophet."

In working on acetylene Berthelot investigated the properties of the acetylides of silver and copper. This work led him in 1866 to make the suggestion that the mineral oils found in the earth might have been formed from acetylene produced by the action of water and carbonic acid on the acetylides of the alkali metals. By treating the carbonaceous matter found in meteorites he produced the liquid petroleum.

Action of Heat on Hydrocarbons.--Berthelot's work on the hydrocarbons included a study of the mode in which these bodies behave under heat. A hydrocarbon, he says, is not directly resolved into its elements, but either polymerises (for example, acetylene into benzene) or by a condensation of two or more molecules forms a larger hydrocarbon with elimination of hydrogen; thus marsh gas is mainly acetylene and hydrogen, ethane yields ethylene and hydrogen, while ethylene yields mainly acetylene and hydrogen. Acetylene itself is not resolved into its elements, but polymerises,

or condenses with hydrogen or other hydrocarbons into compounds of great density—naphthalene, anthracene, etc. When carbon is finally separated, it is therefore not a simple molecule, but in the form of a highly complex group of atoms corresponding with the dense hydrocarbons yielding it. This attractive theory of Berthelot has not, however, been fully borne out by later work. Sir Edward Thorpe showed that the decomposition of a paraffin (under heat and pressure) gave rise to the formation of an olefine and a lower paraffin; and Haber showed that *n*-hexane gave methane and amylene, but confirmed Berthelot's observation that benzene condensed to diphenyl with loss of hydrogen. Bone and his colleagues have shown that methane is formed directly from its elements between 1000° and 1200°, and breaks up again into carbon and hydrogen without forming acetylene. Ethylene, on the other hand, gives acetylene, which itself can either recombine with hydrogen or break down into carbon and hydrogen.

Action of Mass.—The observation made by Berthelot that more was required for the union of glycerol with acids led him, in conjunction with his pupil, Péan de St. Gilles, to investigate the course of the reaction between alcohols and acids, especially that between ethyl alcohol and acetic acid. Here, again, Berthelot was a pioneer in a subject that had hardly been touched experimentally. He found that when equivalent amounts of alcohol and acid are brought together, the reaction proceeds slowly (at a rate depending on the temperature) until a limit is reached, and that the same limit is reached when the corresponding amounts of ester and water are brought together. "An equilibrium is established between the affinity of the acid for the alcohol, which tends to unite them, and the inverse affinity of the water for the neutral ether, which tends to regenerate the acid and the alcohol." We can put the result into an equation:

It is clear, I think, that Berthelot regarded the equilibrium as statical, and not as a dynamical, one; he did not see that the two opposite reactions were taking place at the same time; Guldberg and Waage recognised this, and used Berthelot's figures in the illustration of their principle. Nevertheless, Berthelot and St. Gilles' memoirs form the starting points of much of the subsequent work on equilibrium and mass action. They showed the effect on the equilibrium of varying the amounts of one of the reacting substances; they showed that an increase of temperature or of concentration greatly shortened the time for the equilibrium to be

marked, although pressure alone had little effect. They suggested an equation for the determination of the velocity of a bimolecular reaction similar to that of Harcourt and Esson. Few researches indeed have been more fruitful in physical chemistry than those of Berthelot and St. Gilles. *

Of other equilibrium problems Berthelot was the first to investigate the partition of a dissolved substance between two solvents. He showed, for instance, that when succinic acid is dissolved in ether and water, the coefficient of distribution is constant whatever the amounts dissolved; but other substances showed a variation with concentration, an anomaly explained by Nernst in 1891 as due to a difference of the molecular aggregation of the substance in the two solvents. In 1875 Berthelot studied the partition of acids between several bases in solution.

Thermochemistry.—Berthelot's great work on thermochemistry was begun in 1863, and was continued until 1879, when he published the two volumes entitled, "*Mécanique Chimique fondée sur la thermochimie.*" This and his later book, "*Thermochimie, Données et Lois numériques,*" constitute a monument of elaborate experiment and calculation, which men of science rank alongside the "*Thermochemische Untersuchungen,*" the life-work of Julius Thomsen. It is not at all to the disadvantage of Chemistry that the Frenchman and Dane worked in rivalry. When we want to know the heat of formation of any compound we look up the two authors, and if they agree we are entirely satisfied. I think each respected the other's work. I can point to an instance—the heat of formation of ammonia—where Thomsen corrected his first result, and to another—the heat of formation of ethane—where Berthelot corrected his; in each case as the result of the other's work. They both put forward a theorem, though not quite in the same terms, but every action of a purely chemical nature gives out heat and produces the result that is accompanied with the maximum evolution of heat. Berthelot defended with great skill his "*principle of maximum work*," it required the genius of Helmholtz and Boltzmann to prove that the principle required that the heat of reaction should be independent of the temperature, and was only strictly true at absolute zero. But although these limitations must be accepted, and Berthelot finally accepted them, the "*law*" is nevertheless a useful guide which is often appealed to. Was not Deacon inspired by Berthelot's ideas when he sought and finally found a practical method of liberating chlorine from hydrochloric acid by the oxygen of the air?

Much of the apparatus devised by Berthelot for his thermo-

chemical determinations has come into general use; in particular may mention his "calorimetric bomb" for combustions in oxygen under pressure.

Explosions.—Berthelot's experiences in the war led to his systematic work on explosives and on the theory of explosions. In connection with Vieille he studied the rapidity of combustion and the heat of reaction of various explosives. In July, 1881, he published his first short paper on the explosion-wave in gases. He states that he would not have published it had not M.M. Mallard and Chatelier sent him their memoir on the same subject, which was had attacked by a different method. It is a curious coincidence that a few months before I had myself begun to measure the rate of explosion of carbon monoxide and oxygen with different quantities of water-vapour, and found that the accepted rate was altogether too slow.

Berthelot's first paper contains the germ of his theory of the identity of the rate of explosion with the mean velocity of the molecules formed in the reaction before any heat had been evolved. Other papers quickly followed. Berthelot made the important discovery that the rate of explosion rapidly increased from the point of origin until it reached a maximum which remained constant however long the column of gases might be. This maximum, Berthelot stated to be independent of the pressure of the gas, of the material of the tube, and of its diameter above a small limit. The rate of explosion thus forms a new physico-chemical constant having important theoretical and practical bearings. The term "l'onde explosive" was given by Berthelot to the flame which propagated through an explosive mixture of gases at the maximum velocity, and this velocity could be predicted if the heat of combustion and the density and specific heat of the products were known. For instance, the total heat given out when hydrogen and oxygen combine is known. If this heat is contained in the steam produced its temperature may be calculated if its heat capacity be known, and if the temperature of the steam be known, the mean velocity with which the molecules must be moving can be calculated. Now Berthelot supposed that the heat is all contained in the steam produced. He assumed that the heat capacity of steam was the same as the sum of those of its constituents; and he supposed moreover, that the steam was heated at constant pressure. Making these assumptions, he calculated out the theoretical mean velocity of the products of combustion of various mixtures, and found a close accordance between these numbers and the explosion rates of the same mixtures. He concluded that the explosion-wave was propagated by the impact of the products of combustion of one layer

on the unburnt gases in the next layer, and so on to the end of the tube at the rate of movement of the products of combustion themselves. If this theory be true, it accounts, not only for the extreme rapidity of explosion of gaseous mixtures, and gives the means of calculating the maximum velocity obtainable with any mixture of gases, but it also affords information on the specific heats of gases at very high temperatures, and explains the phenomena of detonation whether of gases or of solid or liquid explosives.

Table I shows the explosion rates found by Berthelot, compared with the theoretical velocity of the products of combustion:

TABLE I.

Gaseous mixture.		Velocity in metres per second.	
		Calculated.	Found.
Hydrogen and oxygen	$H_2 + O$	2830	2810
Hydrogen and nitrous oxide	$H_2 + N_2O$	2250	2284
Carbon monoxide and oxygen	$CO + O$	1940	1090
Carbon monoxide and nitrous oxide ..	$CO + N_2O$	1897	1106
Marsh gas and oxygen	$CH_4 + O_2$	2427	2287
Ethylene and oxygen	$C_2H_4 + O_2$	2517	2210
Ethylene and oxygen	$C_2H_4 + O_2$	2490	2195
Acetylene and oxygen	$C_2H_2 + O_2$	2660	2482

Two facts established by these experiments impressed on me the conviction that Berthelot might have found the true theory of explosions: first, the close coincidence between the rates of explosion of hydrogen (both with oxygen and nitrous oxide) and the calculated velocities of the products of combustion; and, secondly, the great discordance between the found and calculated rates for carbon monoxide with both oxygen and nitrous oxide, for I had previously discovered that pure carbon monoxide cannot be exploded either with pure oxygen or pure nitrous oxide. The discordance found by Berthelot was what I should have expected from my own experiments. Again Berthelot examined the effect of inert gases in damping down the velocity of the explosion-wave; for instance, on adding nitrogen to different explosive mixtures he

TABLE II.

Gaseous mixture.	Velocity in metres per second.	
	Calculated.	Found.
$H_2 + O$	2831	2810
$H_2 + O + N_2$	1935	2121
$H_2 + O + 2N_2$	1820	1439
$CH_4 + 2O_2$	2427	2287
$CH_4 + 2O_2 + 2N_2$	2002	1858
$CH_4 + 2O_2 + 4N_2$	1744	1151
$C_2H_2 + 2O_2$	2490	2195
$C_2H_2 + 2O_2 + N_2$	2334	2044
$C_2H_2 + 2O_2 + 2N_2$	2152	1203

These experiments seemed to Berthelot to show that a small amount of inert gas does not prevent the propagation of the explosion-wave, but damps it down according to its calculated effect. A large amount of inert gas, on the other hand, determines the character of the explosion-wave—which must always be regarded as the “*maximum possible*” velocity.

In comparing the rates of explosion determined in his tube with those calculated from his formula, Berthelot, I think, was justified in his argument that the specific heats of the explosion products must be reckoned as at constant pressure, since the explosion change took place in a closed tube. In the damping experiments with nitrogen he did not allow for the fact that with inert gas a longer run is required before the explosion-wave is set up, and he began to time the flame before it had acquired its maximum pace. In the cyanogen experiments he did not appreciate the fact that in the wavefront the carbon only burns to carbon monoxide. But in spite of these criticisms, which required years of work to establish, I have always thought it one of Berthelot's strokes of genius to identify the maximum velocity of the flame with the mean translational velocity of the molecules themselves, a conception which all later investigators have used in working out the propagation of an intense pressure-wave which preserves its type by being continually reproduced from point to point by its chemical action.

Fixation of Atmospheric Nitrogen.—In Berthelot's synthetic researches we find him using the silent electric discharge to cause nitrogen to enter into combination, for example, as in the direct formation of hydrocyanic acid from acetylene and nitrogen. The fixation of nitrogen led him to investigate its absorption by plants and generally the action of electricity on vegetable growth in his laboratory at Meudon. Berthelot asserted that free nitrogen could be assimilated by plants, a statement that was vehemently opposed until Hellriegel proved that leguminous plants can take up nitrogen through the agency of bacteria. Berthelot was the first to point out that atmospheric nitrogen was fixed in the soil by micro-organisms, a new departure of supreme interest to agriculture. Among other developments of Berthelot's idea, Dr. E. J. Russell has recently shown how the fertility of a soil might be enormously increased by killing off the infusorial enemies of these bacteria. Four solid volumes, entitled, “*La Chimie végétale et agricole*,” published in 1899, contain the record of Berthelot's work at Meudon.

Looking back at the enormous mass of experimental data published by Berthelot I am astonished at the small percentage of

error that has been detected. The accuracy of his experiments is really marvellous. It is not in his experiments, but in his interpretation of them that Berthelot has to meet criticism. Although Berthelot was a rapid worker, he was a still more rapid thinker. Not once or twice, but almost throughout the range of his researches we see the theoretical conception outstripping the experiment. Sometimes deliberately, sometimes unconsciously, he chooses his experiments to illustrate his theory. It is a question of idiosyncrasy: genius must work its own way. The nineteenth century raised Dalton for basing his Atomic Theory on the sure foundation of the Law of Multiple Proportions; the twentieth century knows that Dalton sought for cases of multiple proportion to support his preconceived theory of atoms.

Berthelot's imagination gives a distinction to all his work; his quality of generalisation fascinates us, and compels our interest. When we say which is the better for knowledge--on the one hand, the dash of an explorer into an unknown country, the rapid survey, the approximate location of a great lake and a great mountain range, and the publication of a fascinating sketch-map giving us the possible sources of a Nile or a Congo; or, on the other hand, the deliberate advance of a surveyor with his levels and theodolites? May it not with justice be maintained that had it not been for the pioneer and his map the surveyor would never have started at all? Berthelot might rightly claim that he had pointed out the trend of the country and the possibilities that lay at hand, and had stimulated the curiosity of the exploring world. For myself," he wrote, "I shall be happy if, in the development of science, some of my results are valued some day as the origin of the discoveries of the future." I believe this was no conventional phrase of self-depreciation, but an expression of his thought used with all sincerity.

Again, like other great men, Berthelot found it hard, even when the creatures of his thought had been proved to be "unemployables," to dismiss them from his service. I ventured just now to compare Berthelot's mode of thought with Dalton's. May we extend the parallelism further, and say that the intensity of conception in the mind of each was sometimes too strong to yield to facts? Dalton, firm in his conviction that different elements had atoms of different sizes (the very genesis of his theory), could see neither the relevancy of Gay-Lussac's Law of Volumes nor the beauty of Avogadro's explanation. For him the formula of water was always HO . Berthelot, equally firm in his conviction that in chemical reactions we are dealing with "equivalents," could see the force of Gay-Lussac's experiments, but not of Avogadro's argument. For him

the formula of water (the molecule occupying 2 volumes, H_2O^2).

If we, then, as the result of the steady progress of experiment and thought, can see the limitations of Berthelot's vision, we can also, I hope, appreciate the brilliancy of the conceptions that guided his work, and the intensity of the stimulus given by his ideas to contemporary science.

(3) *The Last Phase.*

Berthelot enjoyed a wonderfully active and honoured old age. To celebrate his seventy-fifth birthday and the jubilee of his appointment in the Collège de France, his colleagues inaugurated a great meeting of congratulation, and commissioned M. Chaplain to design a medal in his honour.

The Chamber of Deputies and the Senate declared that the occasion demanded a public ceremonial, in which the State should participate. Abroad, all the great societies passed resolutions congratulating Berthelot on his achievements, and sent delegates to present their felicitations in person. The meeting was held in the great hall of the Sorbonne on November 24th, 1901. Berthelot declined the procession and the military escort offered by the State and went on foot to the hall. He was received by the President of the Republic. Then amid the acclamation of his colleagues he thronged the hall, he heard perhaps for the first time from the mouths of his most distinguished contemporaries the deep veneration in which the world held his genius and his career. In acknowledging this great demonstration, Berthelot once more insisted on the humanising spirit of science. "It is not," he cried, "for the satisfaction of our private vanity that the world to-day pays homage to men of science. No! it is because it knows that the man of science really worthy of the name consecrates his life disinterested to the great work of our age—the amelioration of the lot of all, the rich and the happy, the poor and the suffering. It is this that my friend Chaplain has sought to express on the beautiful medal which the President of the Republic is to offer me. I know not if I have completely fulfilled the noble ideal the artist has drawn, but at least it has brought me strength to have made this the aim that has directed my life."

"*Pour la Patrie et la Vérité*"—the design was well chosen by Chaplain to sum up Berthelot's career.

Berthelot continued to work to the end. Although he ceased to lecture, he seldom passed a day without visiting his laboratory. There and in his home he found his happiness, for husband and wife seemed to grow nearer as the years went by. In his last months

he had the sorrow of losing a daughter and then a beloved grandson. The shock preyed on his wife, who developed heart disease. Berthelot, himself a victim to the same disease, watched assiduously at her bedside, and wasted his strength in his nightly vigils over her. A Sunday came when she seemed better, and Berthelot visited his laboratory at Meudon, where he was studying the effects of radium emanations on vegetation. On his work table there was found afterwards an alchemic manuscript from Morocco, written in Hebrew, which he was deciphering, for he had not forgotten the early lessons he had received from Renan.

He returned to find his wife failing, and they both knew the end was near. "What will become of him when I am no longer there?" were the last words she spoke to her daughter. Berthelot was alone with his wife when she died. He called his children, kissed the dead, walked into the next room, and threw himself upon a couch. One of his sons followed him, and hearing him sigh, ran to seize his hand. But the hand was lifeless: he had joined his beloved one. The pagan poet whom Berthelot loved has perhaps made us feel more keenly the cry of the heart that cannot survive separation:

"Ah! te meae si partem animae rapit
Maturior vis, quid moror altera,
Nec carus acque nec superstes
Integer! Ille dies utranque
Ducet ruinam. Non ego perfidum
Dixi sacramentum. Ibinus, ibinus
Utrumque praecoles, supremum
Carpere iter comites parati." *

The state procession and military escort which Berthelot had planned alive, were fitting attendants round the hearse that bore the bodies of husband and wife to honourable sepulchre in the Pantheon.

So passed away a great man, full of years and honour. To France and to Science he gave his life, and he was not without reward in the love and veneration of his countrymen. Happy the country that produces such genius; happier still the country that can appreciate and use it.

* At the request of the Publication Committee, I subjoin the English rendering of these stanzas I gave at the Lecture:

"If Death, untimely, snatch away
That half—ah! dearer half—my soul,
Why should this other half delay?
Could life be sweet no longer whole?
The day that strikes thee strikes us both:
Together, when thou goest, we go
Sworn comrades ('tis no idle oath)
To tread the last long path below."

—Horace II. xvii.

INDEX OF SUBJECTS.

TRANSACTIONS AND PROCEEDINGS. 1911.

(Marked T. and P. respectively.)

Single organic compounds of known empirical formula will be found in the Formula Index, p. 2387.

A.

- surprise power, influence of conjugated linkings on (CRYMBLE, NEWART, WRIGHT and GLENDING), T., 451; P., 46; (CRYMBLE, NEWART, WRIGHT and REA), T., 129; P., 133.
- acid, activity of, as catalysts (DAWSON), T., 1.
- hydrolytic activities of (WORLEY), T., 349.
- solubility of salts in the corresponding (MAXSON), T., 1132; P., 125.
- fatty compounds of, with cholesterol (PARTINGTON), T., 313; P., 14.
- halogen derivatives of, rotation of the menthyl esters of the (COHEN), T., 1653; P., 123.
- terpeno-substituted, interaction of esters of, with silver nitrate in alcoholic solution (SENER), T., 95.
- aromo-, menthyl esters of (CHRISTOPHER and HILDITCH), P., 312.
- higher fatty, optically active derivatives of (HILDITCH), P., 311.
- preparation of ketones of (EANTERFIELD and TAYLOR), T., 2298; P., 279.
- organic, separation of mixtures of, by partial esterification (SUDBOROUGH and THOMAS), T., 2307; P., 279.
- saturated and unsaturated, esterification of (THOMAS and SUDBOROUGH), P., 314.
- glycidides, chlorination of (KING and ORSON), T., 1377; P., 196.
- dress, commemorative, to the Royal Academy of Sciences of Turin, P., 272.
- congratulatory, to King George V, P., 184.
- to the University of St. Andrews, P., 185.
- presidential (DIXON), T., 588.

AFFINITY, CHEMICAL:—

- Catalysis by acids (DAWSON), T., 1.
- negative, mechanism of (SENER and PORTER), T., 1049; P., 119.
- Chemical equilibrium of carbon monoxide with carbon dioxide and oxygen (RHEAD and WHEELER), T., 1140; P., 126.
- Dissociation pressure of hydrated salts, determination of (PARTINGTON), T., 466; P., 45.
- Reactivity, relation between, and chemical constitution of nitrogen compounds (CLARKE), T., 1927; P., 243.
- Velocity of addition of alkyl bromides to cyclic tertiary bases (LONG), T., 2164; P., 283.
- Velocity of reaction, measurement of, by means of viscosity (DUNSTAN and MURSELL), T., 565; P., 59.
- influence of neutral solvents on (PATTERSON and MONTGOMERIE), P., 276.
- Air. See Atmospheric air.
- Alcohols, higher fatty, optically active derivatives of (HILDITCH), P., 311.
- of the hydroaromatic and terpene series (PICKARD and LITTLEBURY), P., 324.
- secondary, of the fatty series, rotation of (PICKARD and KENYON), T., 45.
- Aldehydes, aromatic, electrolytic reduction of (LAW), T., 1113; P., 133.
- condensation of, with nitromethane (REMFRY), T., 282; P., 20.
- syn-Aldehydes, preparation of (DUNSTAN and THOLE), P., 233.
- Alkali bicarbonates, the dissociation pressures of (CAVEN and SAND), T., 1359; P., 147.
- Alkalis, action of chlorine on (TAYLOR), T., 1908; P., 243.
- Alkaloïds, isoquinoline. See isoQuinolinc alkaloids.

- Alkyl bromides**, velocity of addition of, to cyclic tertiary bases (LONG), T., 2164; P., 283.
- Alkylammonium nitrites** (RAY and RAKSHIT), P., 71, 264, 291.
- Alkylglyoxalates**, amino- (PYMAN), T., 2173; P., 276.
- Alkylsulfides**, action of hydrogen sulphide on metallic (RUEB), T., 558; P., 60.
- Allium sativum** (garlic), action of, on lead and mercury (BANKER), P., 234.
- Amalgams**. See Mercury alloys.
- Amines**, fatty, action of, on α -dibromosuccinic acid (FRANKLAND and SMITH), P., 320.
- secondary, preparation of, from carboxylic acids (LE SUEUR), T., 827; P., 104.
- Amino-acids**, attempts to prepare glycerides of (ALPERN and WEIZMANN), T., 84.
- Ammonia**, synthesis of, by heat (CARDELL and THOMAS), P., 138.
- direct action of radium on (PERMAN), T., 132; P., 7.
- solubility of cuprous oxide in aqueous solution of (DONNAN and THOMAS), T., 1788; P., 213.
- Ammonias**, substituted, metallic compounds of (LANG), P., 140.
- Ammonium bases**, primary, secondary, and tertiary, preparation of the nitrites of (NEOG), P., 242.
- Ammonium compounds**, quaternary asymmetric (MELDOLA and KUNTZEN), T., 1283, 2034; P., 157, 263.
- Ammonium electrode**. See Electrode under Electrochemistry.
- solutions, studies of (SLADE), T., 1974; P., 242.
- nitrite, preparation of (NEOG and ADHICARY), T., 116.
- cyanate, transformation of, into carbamide (CHAITAWAY), P., 280.
- Anilides**, chlorination of (ORTON and KING), T., 1369; P., 196.
- Anilines**, chlorination of (ORTON and KING), T., 1185; P., 139.
- Annual General Meeting**, T., 577; P., 77.
- Antimony trichloride**, compounds of, with aniline, *p*-chloroaniline and *o*- and *p*-toluidines (MAY), T., 1384; P., 125.
- Antimony organic compounds**, aromatic (MAY), T., 1382; P., 124; (MORGAN and MICKLETHWAIT), T., 2236; P., 274.
- Aromatic compounds**, relation of the velocity of chlorination of, to constitution (ORTON and KING), T., 1369, 1377; P., 196.
- Arylsulpham-carbides and -carbamides**, amino-derivatives of (MORGAN and MICKLETHWAIT), P., 281.
- Asymmetry in the supposed absence of an asymmetric atom** (MAGNAN), P., 185.
- Atmospheric air**, estimation of oxygen in, volumetrically (WATSON), T., 185.
- Atomic weights**, report of the International Committee on, T., 189; P., 202.
- table of, T., 1870; P., 205.
- Arises**, complex (MELDOLA and KUNTZEN), T., 36.
- Azo-compounds**, complex (MELDOLA and KUNTZEN), T., 36.

B.

- Balance Sheets of the Chemical Society and of the Research Fund**. See Annual General Meeting, T., 577; P., 77.
- Bases**, tertiary cyclic, velocity of addition of alkyl bromides to (LONG), T., 2164; P., 283.
- Beer**, solubility of carbon dioxide (FINDLAY and SHEN), T., 1212; P., 189.
- Benzene derivatives**, absorption spectra of (CRYMBLE, STEWART, WILKINSON, and GLENDINNING), T., 451; P., 61.
- Benzole acids**, hydroxy-, oxidative products of (PERKIN), T., 1442; P., 186.
- Benzylidene bases**, electrolytic reduction of (LAW), P., 310.
- Binary mixtures**. See Mixtures, Binary.
- Bleaching**, investigation of the process of (HIGGINS), P., 314.
- Bleaching powder**, action of carbon dioxide on (HIGGINS), T., 854; P., 121; (TAYLOR), T., 1806; P., 243.
- Bromine solutions**, colour and concentration of (JOSEPH and JINENDRARAM), T., 274.
- Bryonol**, $C_{20}H_{32}O_8$.
- Bryony root**, constituents of (POWELL and MOORE), T., 937; P., 118.
- Buehner funnel**, an addition to it (EAGERTON), P., 189.
- Euphane disticha**, constituents of the bulb of (TUTIN), T., 1210; P., 19.
- Euphanine** (TUTIN), T., 1213; P., 19.
- Euphanitine**, $C_{20}H_{32}O_8N_2$.

C.

- Cæsium magnesium chromate** (BARKER), T., 1328; P., 193.
- Calabar beans**, chemical examination of (BALWAY), T., 2148; P., 273.
- Calabareol**, $C_{20}H_{32}O_8$.
- Calcium hydroxide**, dry absorption of the halogens by (WILKS), P., 303.

CIX.

78

Copper:—

- Cupric sulphate, action of sodium hypophosphite on, in aqueous solution (FIRTH and MYERS), T., 1329; P., 139.
- tartrates (PICKERING), T., 169; P., 7.
- Cuprous oxide, solubility of, in aqueous ammonia solutions (DONNAN and THOMAS), T., 1788; P., 213.
- thiocyanate, compound of, and trimethylamine (LANO), P., 140.
- Crystals, dehydration of (FIRTH), P., 237.
- Cupric and Cuprous salts. See under Copper.
- Cyclic compounds, absorption spectra of (CHRYMSE, STEWART, WRIGHT and REA), T., 1262; P., 153.
- D.**
- Datura*, active constituents of species of, from India (ANDREWS), T., 1871; P., 248.
- Density of liquids, determination of the (HARTLEY and BARRETT), T., 1072; P., 100.
- Dipeptides, synthesis of, from α -amino-lauric acid (HORWOOD and WEIZMANN), T., 571; P., 55.
- Diphenylcarbamoyloximes (DUNN), P., 239.
- Dissociation. See under Affinity, chemical.
- Distillation, fractional, pressure regulator for use in (WADE and MERRIMAN), T., 934; P., 64.
- Disulphides, aromatic, synthesis of thioxanthone derivatives from (MARDEN and SMILES), T., 1353; P., 207.
- Interaction of, and sulphuric acid (PRESCOTT and SMILES), T., 640; P., 65.
- Disulphoxides, aromatic, interaction of, with sulphuric acid (HILDITCH), T., 1091; P., 139.
- Double linking, influence of, on optical activity (FRANKLAND and O'SULLIVAN), T., 2325; P., 319.
- Dust explosions, lecture experiment to illustrate (LANG and LLOYD), P., 161.
- Dyeing, theory of (DREAPER), T., 2094; P., 244.
- E.**
- ELECTROCHEMISTRY:—**
- Electrochemistry of solutions in acetone (ROSENDETSKY and LEWIS), T., 2193; P., 266.

ELECTROCHEMISTRY:—

- Cells, concentration, with standard reversible to chlorine gas (LAPWORTH and PARTINGTON), T., 184; P., 184.
- Electrodes, ammonium (BLAIR), T., 1974; P., 242.
- Cu/Cu₂O alkali/H₂, potentials of (ALLMAND), T., 840; P., 66.
- hydrogen, in alcohol (HARDMAN and LAPWORTH), T., 2242; P., 244.
- Hg/H₂O alkali, potentials of in (DONNAN and ALLMAND), T., 1788; P., 70.
- Electrolytes, solubility of, in aqueous solutions (MASON), T., 1222; P., 125.
- alkaline, electrolytes with (ALLMAND), T., 840; P., 69; (DUNN and ALLMAND), T., 845; P., 77.
- Electrolytic dissociation, relation of molecular association to (TILLEY), T., 880; P., 40.
- Electrolytic reduction of aromatic aldehydes (LAW), T., 1113; P., 138.
- of benzylidene bases (LAW), P., 84.
- Electromotive force, measurement of, in alcohol (LAPWORTH and PARTINGTON), T., 1417; P., 184; (HARDMAN and LAPWORTH), T., 2242; P., 244.
- Ionisation in non-aqueous solutions (DAWSON and LESLIE), T., 1667; P., 208.
- Electromotive force. See under Electrochemistry.
- Elements, fundamental properties of (RICHARDS), T., 1201; P., 159.
- Equilibrium, chemical. See under Affinity, chemical.
- Phase rule, simple demonstration of (PARTINGTON), P., 13.
- Explosions, the initiation and propagation of (DIXON), T., 589.
- F.**
- Faraday lecture (RICHARDS), T., 1332; P., 178.
- Ferrocyanides. See under Iron.
- Fluorone derivatives (PARK and HARRIS), T., 545; P., 52.
- G.**
- Garlic. See *Allium sativum*.
- Gases, liquified, binary mixtures of (BAGSTER), T., 1218; P., 141.
- Glycosides, effect of, on solutions of salts (GLOVER), T., 379.
- Gintaconic acids, chemistry of the (THOLE and THORPE), T., 2187, 2204; P., 122, 252.

ammonia, formation of (EVERETT and McCORMICK), T., 1746; P., 302.
 alloys with palladium, occlusion of hydrogen by (BERRY), T., 463; P., 54.
 gas-liquids, application of (DAVIES and KIRKPATRICK), T., 296; P., 39.
 lime, reactions of (SIMONSEN), T., 330; P., 191.

H.

hydrogen, reactivity of the, in organic compounds (SENTER), T., 85; (SENTER and PORTER), T., 1049; P., 119.
 absorption of, by dry slaked lime (WILSON), P., 308.
 rate of vaporization. See under Thermodynamics.
 rate, determination of the vapour pressure of (PARTINGTON), P., 12.
 rate values, determination of (WORTH), T., 349; (GLOVER), T., 371.
 reaction, decomposition of, by heat (HATTAWAY, CUMMING and WILSON), T., 1950; P., 193.
 reaction, auto-reduction of (CHATTAPAY and ALDRIDGE), T., 404.
 reaction, decomposition of, by heat (HATTAWAY, CUMMING and WILSON), T., 1950; P., 193.
 reaction, synthesis of, at high temperatures (PRIMO and FAIRLIE), T., 1796; P., 217.
 reaction, combustion of mixtures of, with air (BURGESS and WHEELER), T., 2013; P., 262.
 reaction, acid. See under Chlorine.
 reaction, occlusion of, by the palladium-gold alloys (BERRY), T., 463; P., 54.
 reaction. See Electrode, under Electrochemistry.
 reaction peroxide, action of, on thiobenzamide (LEES and BARNETT), P., 120.
 reaction, action of, on sodium and potassium ethoxides (RELE), T., 338; P., 60.
 reaction, optically active, and their reaction, action of thionyl chloride and sulphur pentachloride on (MCKEN and BARROW), T., 1910; P., 232.
 reaction, aromatic, substitution (HARDING), T., 1585; P., 213.
 reaction, aromatic, action of phuric acid with (HLEDITCH and HILL), T., 973; P., 123.
 reaction, action and chemical constitution (RUMFAT), T., 610; P., 72.

I.

iodine, complex (MELDOLA and KUNTER), T., 36.
 iodine-compounds, formation and reactions of (THOLE and THORPE), T., 422, 1684; P., 42, 219.
 indicators of the methyl-red type (HOWARD and POPE), T., 1333; P., 204.
 ionisation. See under Electrochemistry.
 Ipomoea orizabensis, constituents of the root of (POWER and ROGERSON), P., 304.
 iodine acid. See under Iodine.
 iodine, reactivity of ketones towards (DAWSON and ARK), T., 1740; P., 223.
 iodine acid, velocity of the reaction between sulphurous acid and (PATERSON and FORSYTH), P., 320.
 iron, action of steam on, at high temperatures (FRIEND, HILL and BROWN), T., 969; P., 124.
 action of salt solutions and of sea-water on (FRIEND and BROWN), T., 1302; P., 156.
 passivity and rusting of (DUNSTAN and HILL), T., 1835, 1853; P., 221, 222.
 porosity of, and its relation to passivity and corrosion (FRIEND), P., 311.
 iron organic compounds:—
 ferrocyanides, isomerism of (BRIGGS), T., 1019; P., 24.
 organic, constitution of (HARTLEY), T., 1549; P., 211.

K.

ketones, reactivity of, towards iodine (DAWSON and ARK), T., 1740; P., 223.
 of higher fatty acids, preparation of (EASTFIELD and TAYLOR), T., 2298; P., 279.
 hydroaromatic (CROSSLEY and RENOFF), T., 1101; P., 137.
 ketoximes, preparation of (LAPWORTH and STEELE), T., 1884.
 Kirchhoff's equation, application of, to solutions (HARDMAN and PARTINGTON), T., 1769; P., 221.

L.

lead, action of *Allium sativum* on (BANERJEE), P., 234.
 lime, slaked. See Calcium hydroxide.
 liquids, determination of the density of (HARTLEY and BARRETT), T., 1072; P., 100.

Liquids, mixed, latent heats of vaporization of (TYRRE), T., 1835; P., 215, 319.
 Lithium periodate (BARKER), T., 1326; P., 198.

K.

Magnesium cesium and rubidium chromates (BARKER), T., 1327; P., 198.
 Manganese:—
 Permanganates, absorption spectra of (MERTON), T., 637; P., 66.
 Manometer, glass, some forms of (JACKSON), T., 1066; P., 45.
 Matches, characteristics and composition of early (CLAYTON), P., 229.
 Menthol (PICKARD and LITTLEBURY), P., 324.
 Memorial lecture, Berthelot (DIXON), T., 2353; P., 270.
 Mercury, reducing actions of (BORAR), T., 1414; P., 128.
 influence of ferric salts and of manganese nitrate on the rate of solution of, in nitric acid (RAY), T., 1012; P., 4.
 action of *Allium sativum* on (BANERJEE), P., 234.
 mercuric oxide electrode. See Electrode under Electrochemistry.
 Mercury alloys (amalgams), with silver and tin (JOYNER), T., 195; P., 8.
 Mesothorium, chemistry of (SONNY), T., 72.
 Metallic ions, relation between the absorption spectra of, and their valency (CRYMBLE), P., 68, 328.
 oxides, action of, with phosphoryl chloride (BASSETT and TAYLOR), T., 1402; P., 155.
 Metals, aerial oxidation of (DUNSTAN and HILL), T., 1835; P., 221.
 passivity of (DUNSTAN and HILL), T., 1853; P., 222.
 action of hydrogen sulphide on the alkylloxides of (RULE), T., 553; P., 60.
 Mixtures, binary, of liquefied gases (BAGSTER), T., 1218; P., 141.
 Molecular association in water (FEDDLE and TURNER), T., 685; P., 8.
 association and its relation to electrolytic dissociation (TURNER), T., 880; P., 40.
 refraction and rotation. See under Photochemistry.
 Muscle, living, reactions between chemical compounds and the proteins of (VELEY), T., 180; P., 3.
 Myrica Gale, L., constituents of the oil of (PICKLES), T., 1764; P., 220.

K.

Naphthylamines, isomerism of (KIDOLA), P., 38.
 Naphthylideneoximes (SESTER and CLARKE), T., 2081; P., 264.
 Nitro-compounds, condensation of with uridine with (HORE and HOWARD), T., 2114; P., 265.
 Nitrogen, compounds of, relation between reactivity and chemical constitution of (CLARKE), T., 1927; P., 322.
 Nitric acid, decomposition of, by heat (REYNOLDS and TAYLOR), P., 326.
 action of nascent hydrogen on (BANERJEE and BASILEZ), P., 326.
 influence of metallic nitrates on the solution of copper in (REYNOLDS and COOKE), T., 1035; P., 42.
 influence of ferric salts and of manganese nitrate on the rate of solution of mercury in (RAY), T., 1012; P., 4.
 Nitrogen, estimation of, in organic compounds (FRANKLAND), T., 1731; P., 307, 309.
 Nitro group, orientation of, in isomycinic acid (SALWAY), T., 20; P., 20.
 Nitrohydroazo-compounds, alkaline condensations of (GREEK and BRADEN), T., 1960; P., 228.

Water, molecular association in (PEDDLE and TURNER), T., 685; P., 8.

influence of, on the boiling point of ethyl alcohol, at various pressures (WADE and MERRIMAN), T., 997; P., 65.

Water of crystallisation in hydrated salts (BAKER and ADLAM), T., 507; P., 17.

Spring and mineral waters, occurrence of pentathionic acid in (MACLAURIN), P., 10.

Sea-water, action of, on iron (FRIEND and BROWN), T., 1302; P., 156.

Wax, *Candelilla*, constituents of (SANDERS), P., 250.

Withania somnifera, constituents of (POWER and GALWAY), T., 490; P., 53.

Withanic acid, $C_{20}H_{40}O_8$.

Withniol, $C_{22}H_{42}O_2$.

Y.

Yeast, influence of salts on the autofermentation of (HARDEN and PAINE), P., 103.

FORMULA INDEX.

The following index of organic compounds of known empirical formula is arranged according to Richter's system (see *Lexikon der Kohlenstoff-Verbindungen*).
The elements are given in the order C, H, O, N, Cl, Br, I, F, S, P, and the remainder alphabetically.

The compounds are arranged—
Firstly, in groups according to the number of carbon atoms (thus C_1 group, C_2 group, etc.).

Secondly, according to the number of other elements besides carbon contained in the molecule (thus 5 IV indicates that the molecule contains five carbon atoms and four other elements).

Thirdly, according to the nature of the elements present in the molecule (given in the above order).

Fourthly, according to the number of atoms of each single element (except carbon) present in the molecule.

Simple metallic salts of acids are indexed under the respective acids.

Simple salts of bases (for example, hydrochlorides, platinichlorides, and picrates), when described for the purpose of further identifying the base, are indexed under the latter.

C_1 Group.

CH_4 Methane, equilibrium of the formation of (PRING and FAIRLIE), P., 305.

CO Carbon monoxide, effect of temperature on the dissociation equilibrium of (RUSAD and WHEELER), T., 1149; P., 126; photochemical and thermal reaction of chlorine with (CHAPMAN and GEE), T., 1726; P., 223.

CO_2 Carbon dioxide, rôle of, in bleaching processes (HUGGINS), T., 858; P., 67.

I II

CH_2O_2 Formic acid, interaction of, and cellulose (CROSS and BEVAN), T., 1450; P., 149.

CH_3N Methylamine, nitrite of (RAY and RAKSHIS), T., 1016; P., 22.

I III

CH_3ON Nitromethane, condensation of aromatic aldehydes with (REMFREY), T., 282; P., 20.

CH_3ON_2 Carhamide, transformation of ammonium cyanate into (CHATTAWAY), P., 280.

I IV

CH_3ON_2Cl Dichlorocarbamide, formation of, and its behaviour with amines (DATT), P., 264.

CH_3O_3SP Methyl dihydrogen α -thiophosphate, disodium salt (+ $6H_2O$) (KEMMETT and JONES), T., 719; P., 72.

C_2 Group.

CH_2O Glyoxylic acid (+ H_2O), brucine salt of (HILDRITCH), T., 234.

CH_2O_2 Oxalic acid, solubility of, in other acids (MASSON), P., 328; stability of the double salts of, with sodium and nickel and with sodium and cobalt (DODGSON), P., 260.

$C_2H_4O_2$ Acetic acid, purification of (ORTON, EDWARDS and KING), T., 120; P., 120; purification and properties of (BOUWFIELD and LOWRY), T., 142; P., 187; ethyl acetate, ethyl alcohol and water, equilibrium between (JONES and LAPWORTH), T., 1427; P., 143; detection and estimation of small quantities of acetic anhydride in (EDWARDS and ORTON), T., 1181; P., 121.

$C_2H_4O_2$ Glycolaldehyde, bimolecular (McCLELAND), T., 1827; P., 224.

$C_2H_4O_2$ Glycollic acid, alkaline cupric salts of (PICKERING), T., 1347; P., 192.

$C_2H_4O_2$ Ethyl alcohol, influence of water on the boiling point of, at various pressures (WADE and MERRIMAN), T., 997; P., 65; influence of temperature on the basic water value of (JONES and LAPWORTH), T., 917; P., 100; acetic acid, ethyl acetate and water, equilibrium between (JONES and LAPWORTH), T., 1427; P., 143; heat of hydrolysis of the hydrochloride of (JONES and LAPWORTH), P., 143; potassium salt, action of hydrogen sulphide on (RILEY), T., 558; P., 60; sodium salt, action of hydrogen sulphide on (RILEY), T., 548; P., 60.

$C_2H_5N_3$ β -Triazethylamine, and its hydrochloride (FORSTER and NEWMAN), T., 1278; P., 154.

C_2H_5N Dimethylamine, nitrite of (RAY and RAKSHIT), T., 1472; P., 122.

Ethylamine, nitrite of (RAY and RAKSHIT), T., 1470; P., 12, 122.

2 III

$C_2H_2O_5$ Dithiooxalic acid, complex salts of (ROBINSON and JONES), P., 371.

C_2H_2OCl Acetyl chloride, condensation of, with salicylamide (FITZGERALD and HICKS), T., 866; P., 102.

C_2H_2ON Glycine, interaction of elloxan and (HARTLEY and WOOTTON), T., 234; P., 2.

C, Group.

C_2H_2O Mesoxalic acid (+ H_2O), brucine salt of (HILDITCH), T., 235.

C_2H_2O Pyruvic acid, brucine salt of (HILDITCH), T., 234.

C_2H_2O Acetone, electrochemistry of solutions in (ROSHIDETWENSKY and LEVINE), T., 2138; P., 286; condensation of, in the presence of phosphoric acid (NAGAI), T., 1249; P., 71.

C_2H_5N Trimethylamine, compound of, and cuprous thiocyanate (LAWSON), P., 140.

$C_2H_5N_2$ Malonamide, condensation of, with ethyl and methyl diethylmalonate (BEMFRET), T., 820.

C_2H_5N Trimethylamine, nitrite of (RAY and RAKSHIT), T., 1472; P., 122.

Propylamine, nitrite of (RAY and RAKSHIT), P., 291.

3 III

$C_2H_3ON_2$ Cyanoacetamide, preparation of (THOLE and THORPE), T., 429.

$C_2H_3ON_2$ β -Triazethylcarbamide (FORSTER and NEWMAN), T., 1281; P., 154.

3 IV

$C_2H_3O_2SP$ Trimethyl α - and β -thiophosphates, preparation of (EMMETT and JONES), T., 713; P., 72.

C, Group.

C_2H_2O Oxalacetic acid, brucine salt of (HILDITCH), T., 235.

C_2H_2O Crotonaldehyde, condensation of (SMEDLEY), T., 1627; P., 208.

C_2H_2O Acetoacetic acid, brucine salt of (HILDITCH), T., 234.

- LA** Acetic anhydride, detection and estimation of small quantities of, in acetic acid (EDWARDS and ORTON), T., 1181; P., 121.
- LA** Succinic acid, brucine hydrogen salt of (PICKARD and KENTON), T., 60.
- LA** L-Malic acid, influence of electrolytes on the optical activity of, in aqueous solution (STRAUM), T., 2365; P., 225.
- LA** Tartaric acid, salts of (HILDITCH), T., 236; cuprio salts of (PICKERING), T., 169; P., 7.
- LA** 4(or 5)-Methylglyoxaline, derivatives of (EWING), T., 2052; P., 259.
- LA** 4(or 5)-Aminomethylglyoxaline, salts of (PYMAN), T., 2175.
- LA** Ethyl acetate, acetic acid, ethyl alcohol and water, equilibrium between (JONES and LARWORTH), T., 1427; P., 143.
- LI** 1-Iodobutane (PICKARD and KENTON), T., 65.
- LO** Ethyl ether, physical properties of mixtures of sulphuric acid and (FORN), T., 698; estimation of traces of water in (TYNER), P., 142.
- LO** Trimethylcarbinol, cryoscopic ebullioscopic and association constants of (ARTINA), T., 10.
- LO** 2- and 4-Methylethylcarbinol, and their derivatives (PICKARD and KENTON), T., 59, 60, 64.
- LN** n-Butylamine, salts of (HILDITCH), T., 236; nitrite of (RAY and RAKSHIT), P., 291.

4 III

- LO,N** Alloxan, interaction of, and glycine (HURTLEY and WOOTTON), T., 288; P., 2; relation of, to triketohydrindene hydrate (RUEHMANN), T., 792; P., 97.
- LO,Br** s-Dibromosuccinic acid, action of aliphatic amines on (FRANKLAND and SMITH), P., 320; action of benzylamine on (FRANKLAND), T., 1775; P., 206.
- Dibromosuccinic acids, configuration of the stereoisomeric (MCKENZIE), P., 150.
- LO,N,Cl** 4(or 5)-Chloromethylglyoxaline, and its salts (PYMAN), T., 675; P., 91.
- LO,N** 4(or 5)-Hydroxymethylglyoxaline, and its salts (PYMAN), T., 673; P., 91.
- LO,S** 2-Thiol-4(or 5)-aminomethylglyoxaline, and its salts (PYMAN), T., 672; P., 91.

- $C_{10}H_{10}OBr$ Substance, from the preparation of bromo- α -camphoronic acid (HENDERSON and HEILBRON), T., 1894.
- $C_{10}H_{10}O_2N$ Imide of cyclohexane-1:1-diacetic acid, and its silver salt (THOLE and THORPE), T., 445.
- Substance, from bornylene and nitrous acid (HENDERSON and HEILBRON), T., 1898; P., 249.
- $C_{10}H_{10}O_2Br$ Bromocamphenanic acid (HENDERSON and SUTHERLAND), T., 1544; P., 211, 278.
- Bromocamphenilanic acid (HENDERSON and HEILBRON), T., 1894; P., 249.

- H_2O_2 Pernitrosocamphorquinoneoxime (FORSTER, TROTTER and NEWMAN, T., 1990).
- H_2O_2 Phenene nitrosoazide, two isomerides (FORSTER and NEWMAN, T., 1990).
- H_2O_2 Phenene nitrosoazide (FORSTER and VAN GELDEREN, T., 2062; P., 195).
- H_2O_2 Phenene nitrosoazides (FORSTER and VAN GELDEREN, T., 2064; P., 195).
- H_2O_2 Phenene hydrosulphide, action of hydrogen cyanide on (SIEFEL, T., 1990).
- H_2O_2 Phenyl-diethylsilicof (KIPPING and HACKFORD, T., 141; P., 9).
- H_2O_2 Pernitrosocamphor, constitution of (FORSTER, TROTTER and NEWMAN, T., 1992; P., 259).
- H_2O_2 Phenyl nitrosoazide (FORSTER and VAN GELDEREN, T., 2067).
- H_2O_2 Bornylene nitrosites (HENDERSON and HEILBRON, T., 1896; P., 199).
- H_2O_2 Bornylene nitrosoamphane (HENDERSON and HEILBRON, T., 1899; P., 249).
- H_2O_2 Bornylene sulphonic acid, salts of (HENDERSON, T., 236).
- H_2O_2 1-Acetyl-2-methylaminolauronic acid (WEISS, T., 1274; P., 154).
- H_2O_2 1-Acetyl-2-methylaminolauronic acid (WEISS, T., 1274; P., 154).
- H_2O_2 Semicarbazone of *d*-3-acetyl-1-methyl- Δ^2 -cyclohexene (HAWORTH and WALLACH, T., 129).
- H_2O_2 Substance, from bornylene and nitric acid (HENDERSON and HEILBRON, T., 1900; P., 249).
- H_2O_2 Semicarbazone of ethyl 1-methylcyclopentan-4-one-2-carboxylate (HAWORTH and PERKIN, T., 770).
- H_2O_2 Terphenyl nitrosoazide (FORSTER and NEWMAN, T., 250; P., 20).
- H_2O_2 1,2,3-Trimethylcyclohexan-3-one semicarbazone (CROSSLEY and HARRIS, T., 1119).
- H_2O_2 Semicarbazone of *d*-3-acetyl-1-methylcyclohexan-3-ol (HARRIS and WALLACH, T., 131).
- H_2O_2 3-Acetyl-3-methylhexoic acid semicarbazone (CROSSLEY and HARRIS, T., 1111).

10 IV

- $\text{H}_2\text{O}_2\text{Br}$ Chloro-2-bromo- α -naphthol (KING, P., 267).
- $\text{H}_2\text{O}_2\text{S}$ 1-Nitroso-2-naphthol-3:6-disulphonic acid, sodium salt (KING, MAY, P., 141).
- $\text{H}_2\text{O}_2\text{Cl}$ 4-Chloroacetyl-amino- α -phenylacetamide (CLARKE and FRANK, P., 724).
- $\text{H}_2\text{O}_2\text{Cl}$ 5-Chloroaceto-*o*-xylidide (ORTON and KING, T., 1188).
- $\text{H}_2\text{O}_2\text{Cl}$ 5-Chloroaceto-*o*- and *p*-phenetidides (ORTON and KING, T., 1190).
- $\text{H}_2\text{O}_2\text{Cl}$ 2,4-Dichloro-3:5-dimethoxyphenylethylamine, hydrochloride (KING, T., 1323).
- $\text{H}_2\text{O}_2\text{BrS}$ 1 and 2-Bromocamphorsulphonic acids, *d*- and *l*-narcotine salts (PERKIN and ROBINSON, T., 788).
- $\text{H}_2\text{O}_2\text{Cl}$ 1,2,3-Trimethylcyclohexenone semicarbazone (CROSSLEY and HARRIS, P., 1197).

C₁₁ Group.

- H_2 8-Methyl- Δ^1 -decadiene (HARDING, WALSH and WEIZMANN, T., 450).

11 II

- H_2O Ethyl coumaranonecarboxylate, metallic salts of (MERRIMAN, T., 102; P., 101).
- Substance from α -bromomethylfurfuraldehyde and barium carbonate (COOPER and HARRIS, T., 1260; P., 135).

- $C_{11}H_{10}O_5$ 5-Methoxy-3-methylphthalide-2-carboxylic acid, acid salt (MELNIK, T., 1717.
3-Methoxy-5-methylphthalide-2-carboxylic acid, acid salt (MELNIK
MELNIK, T., 1718.
 $C_{11}H_{12}O_5$ 4:5-Dimethoxy-1-hydrindone (PERKIN, ROBERTS and LEECH,
P., 58.
 $C_{11}H_{12}O_5$ 2:3-Dimethoxydinamic acid (PERKIN, ROBERTS and LEECH,
P., 58.
 $C_{11}H_{12}O_5$ 2:4- and 2:5-Diacetoxyanisole (MOORE, T., 1945; P., 171.
 $C_{11}H_{12}O_5$ Ethyl *d*- and *l*-hydroxy β -phenylpropionate (MARRAS and
HARROW, T., 1921.
 $C_{11}H_{12}O_5$ 2:3-Dimethoxy β -phenylpropionic acid (PERKIN, ROBERTS and
ROBINSON, P., 58.
 $C_{11}H_{12}O$ Benzylmethyl ethyl carbinol, preparation of (HARRIS and
T., 265.
 $C_{11}H_{12}O_5$ $\alpha\alpha$ -Diacetoacetin (ALLEN and WEIZMANN), T., 45.
 $C_{11}H_{12}O_5$ Ethyl α -methyl- γ -ethylglutaconate (THORPE and THORPE,
Ethyl 1-acetoxy-1-methylcyclopentane-2-carboxylate (HARRIS and
T., 771.
 $C_{11}H_{12}O_5$ Methyl θ -aldehydonononoate (HARRIS, WALSH and WEIZMANN,
T., 451.
 $C_{11}H_{12}O$ $\alpha\alpha$ -Dimethyl- Δ^8 -nonenyl alcohol (HARRIS, WALSH and WEIZMANN,
T., 150.
 $C_{11}H_{12}O$ *dl*- and *d*-Methyl α -nonylcarbinols, rotation and density
(PICKARD and KENYON, T., 59, 60, 70.

II III

- $C_{11}H_{10}O_4N_4$ Nitro-6-acetylaminocoumarin (CLAYTON, P., 245.
 $C_{11}H_{10}O_2Cl_2$ 5- (or 3)-Methoxy-3- (or 5)-methyl-2-trichloromethyl-1,4-
(MELDRUM, T., 1716.
 $C_{11}H_{10}O_2Cl$ Ethyl β -chlorocinnamates, isomeric (JAMES, T., 1926.
 $C_{11}H_{10}O_4N$ *o*-N-Diacetylsalicylamide (TITHERLEY and HOOKS, T., 192.
 $C_{11}H_{10}O_4N$ 2:5a-Nitroso-4:5-dimethoxy-1-hydrindone (PERKIN, ROBERTS and LEECH,
SON), P., 58.
 $C_{11}H_{11}O_2N$ Ethyl nitromyristicinate (SALWAY, T., 265.
 $C_{11}H_{13}ON_4$ β -Triazooethylquinolinium hydroxide, salts of (FORSTER and
NEWMAN, T., 1282.
 $C_{11}H_{13}O_2N_3$ Tryptophan, preparation of the betaine of, and its conversion
hypaphorine (VAN ROMBIEGH and BARGER, T., 2068; P., 25.
 $C_{11}H_{13}ON$ Substance, from α -methylglutaconic acid *trans*-semiamide (THORPE and
THORPE), T., 2231.
 $C_{11}H_{13}O_2N$ α -Carbethoxyamino- α -phenylacetic acid (CLARK and FAY,
T., 322.
Amide of α -carboxyphenylglycolic acid (MERRIMAN, T., 232; P., 22.
 $C_{11}H_{13}O_2N$ Ethyl aminomyristicinate (SALWAY, T., 265.
 $C_{11}H_{13}O_2N_3$ Dinitrovaleryl-*p*-aminophenol (MELDRUM and KISTEN, T., 192.
 $C_{11}H_{13}O_2N_3$ α -Carbethoxyamino β -phenylacetamide (CLARK and FAY,
T., 322; P., 22.
 $C_{11}H_{13}ON$ *neo*-Cyanodihydrocarvone (LAPWORTH and STEELE, T., 1885.
 $C_{11}H_{13}ON_2$ Phenyl isopropyl ketone semicarbazone (LAPWORTH and
STEELE), T., 1885.
 $C_{11}H_{13}O_2N$ β -3:5-Dimethoxyphenylpropionamide (SALWAY, T., 192.
Nitromethylenecamphor (FORSTER and WITHERS, P., 327.

11 III-12 II

- N*-acetylaminoxypropyloltrimethyl ether; - H₂O (HARDING), T., 1937.
- N*-methylamethotriazine (FORSTER and ZIMMERLIN, T., 489; P., 50).
- Isomers of cyanodihydrocarvone (LAWORTH and STEELE), T., 1936.
- Ester of 5-glyoxalinemethylmethylenesuccinate and its salts (REMPKY, T., 1293).
- Methylethylmalonylethylmalonamide (REMPEY, T., 618).
- Cyanomethylmalonamide (REMPEY, T., 618).
- 5-Glyoxalinemethylmalonate, and its salts (PYMAS, T., 1390).
- Cyanodihydrocarvonecarboxylic acid (LAWORTH and STEELE), T., 1936.
- N*-hydroxycarboxymethylaminolauroic acid (WEIR, T., 1274).
- N*-methylhydroxyamphor (FORSTER and WIDHELS, P., 327).
- Semicarbazones of *b*, *i*, and *d* triazodihydrocarvone (FORSTER and ZIMMERLIN, T., 2063; P., 195).
- Triallylthioallicol (KITTING and HACKETT, T., 140; P., 9).
- 1-Isobutoxy-3-propyl-2-butyltetrahydropyrimidine (REMPEY, T., 1294).
- Semicarbazone of coccamphenylaldehyde (HISTOROFF and GUNZ, T., 1546; P., 211).
- N*-isomericarbazone (LANSHIRE and PERKIN, P., 167).
- N*-hydroxymethylaminolauroic acid (WEIR, 1273; P., 154).
- α -Amino- γ -hydroxyglycine (HOWWOOD and WEIZMANN, T., 1578).

11 IV

- ONBr** Benzylamine bromomalonate (FRANKLAND, T., 1779, P., 208).
ONCl 4-Oxobutanoic acid chloride (ORON and KING, T., 1189).
ONCl Ethyl 4-oxo-5-glyoxylohexamethylchloromalonate, and its salts (ORON, T. 1393, P., 92).
ONS Camphorquinone- α - and β -thiosuccinylcarbazones (FORSTER and HART, T., 1874, P., 50).
ONCl Semicarbazone of chloroamphor (HENDERSON and HEILBRON, T., 1913, P., 218).
ONBr α -Bromo-nonylglycine (HOFMANN and WEIZMANN), T., 1914, P., 214.

C₁ Group.

- Diphenylene (DOBBIE, FOX and GAUGE), T., 683; P., 90.

12 11

- [Cl.] 2,2-Dichlorodiphenyl (DOBBIE, FOX and GAUGE, T., 1615; P., 217.
- [Br.] 2,2-Dibromodiphenyl (DOBBIE, FOX and GAUGE, T., 1615; P., 217.
- [O.] 2-Hydroxy-3-benzyl-4-pyrone, and its potassium and silver salts (TOLZ and THORPE, T., 2229.
- [O.] 2,4-Dihydroxydiphenyl (PERKINS, T., 1417; P., 195.
- [O.] 2-Benzylglutaconic acid, and its silver salt (TOLZ and THORPE, T., 2229.
- [O.] Lactone of 2-hydroxy-4-acetoxy-5-methoxy- β -phenylpropionic acid (MOORE, T., 1048; P., 119.
- [N.] 2,6,6-Trimethylpicoline, salts of (JONES and EVANS, T., 338.
- [O.] Ethyl phenylacetronate (SUDBOROUGH and THOMAS, T., 2314.
- [O.] 2,4,5-Trimethoxycinnamic acid (MOORE, T., 1047; P., 119.

- $C_{12}H_{14}O_2$ β -Phenyl- β -methylvaleric acid, and its silver salt (SOLLA, T., 46.
 $C_{12}H_{14}O_3$ 2:4:5-Trimethoxy- β -phenylpropionic acid (MILTON, T., 120.
 $C_{12}H_{14}N_2$ Base, from *Withania somnifera*, and its salts (POWELL and TAYLOR, T., 496; P., 53.
 $C_{12}H_{13}N$ 2:6:8-Trimethyltetrahydroquinoline, salts of (SOLLA and TAYLOR, T., 337.
 $C_{12}H_{18}O_3$ Ethyl 1-methylcyclopentan-2-one-3:4-dicarboxylate (PERKIN, T., 774.
 Ethyl 1-methylcyclopentan-4-one-dicarboxylate (HARRIS and PERKIN, T., 768.
 $C_{12}H_{20}O_4$ Ethyl lactone of β -methyl- γ -hydroxypropyric acid (PERKIN, T., 758.
 Ethyl α -methyl- γ -ethylglutamate (THOLE and THORPE, T., 447.
 $C_{12}H_{24}O_2$ *d*-Methylhexylcarbinyl α -butyrate (HILTON, T., 222.
 $C_{12}H_{20}O_2$ α -Aminolauric acid, synthesis of dipeptides of (HILTON and WEIZMANN, T., 571; P., 55.
 $C_{12}H_{26}O$ *dl*- and *d*-Methyl-decylcarbinols, and their derivatives (HARRIS and KENYON, T., 54, 60.
n-Octylpropylcarbinol, isolation of (PICKARD and KENYON, T., 55).

12 III

- $C_{12}H_8O_2N$ Nitroacenaphthene, reduction of (CHROMIEN and WAGNER, T., 224.
 $C_{12}H_8O_2Cl$ 6-Chloro-3-benzyl- α -pyrone (THOLE and THORPE, T., 447.
 $C_{12}H_8O_2N$ 1- ω -Nitrovinyl- β -naphthol (+2H₂O) (REMFRY, T., 224; P., 21.
 $C_{12}H_{10}O_2N_4$ 1:4'-Nitronitrosohydrazobenzene (GREEN and THORPE, T., 1968; P., 229.
 $C_{12}H_{10}O_2Si$ Anhydride of phenylmetasilicic acid (KIRKPATRICK and HARRIS, T., 144; P., 9.
 $C_{12}H_{13}O_2N$ *cis*- and *trans*-Semianilides of α -methylglutamic acid (HARRIS and THORPE, T., 2231.
 Ethyl cinnamoylcarbamate, preparation of (REMFRY, T., 224.
 Cotarnine, condensation of, with nitro-compounds (HARRIS and THORPE, T., 2114; P., 265.
 $C_{12}H_{13}O_2N$ Ethyl ω -nitrostyryl-*m*- and *p*-oxyacetates (REMFRY, T., 224; P., 21.
 $C_{12}H_{13}O_6N_3$ Diacetyl derivative of 4:6-dinitro-*o*-3-xylydine (CHAPMAN and MORRELL, T., 2349.
 $C_{12}H_{14}O_2N_4$ Diimino-diimide of cyclohexane-1:1-dimalonic acid and its salts (THOLE and THORPE, T., 447.
 $C_{12}H_{14}O_2N_2$ α -Ethylloxalylamino- α -phenylacetamide (CHAPMAN and MORRELL, T., 324.
 Diimide of cyclohexane-1:1-dimalonic acid (THOLE and THORPE, T., 447.
 Anhydrohydrastinine-dimethane, and its salts (HARRIS and ROBINSON, T., 2136.
 $C_{12}H_{14}O_2N_2$ ω -Imide of α -cyano- α' -carbamyloxylohexane-1:1-dialdehyde (THOLE and THORPE, T., 444.
 $C_{12}H_{14}O_2N$ Imide of cyclohexane-1:1-dimalonic acid (THOLE and THORPE, T., 444.
 $C_{12}H_{14}O_2N_4$ ω' -Imino-imide of α -cyano- α' -carbamyloxylohexane-1:1-dialdehyde, and its platinichloride (THOLE and THORPE, T., 443.
 $C_{12}H_{16}O_2N_2$ α -Carbethoxyamino- α -*p*-methoxyphenylacetamide (HARRIS and FRANCIS, T., 323.
 $C_{12}H_{16}O_2N$ 4:6-Dimethoxy-2- β -methylaminoethylbenzaldehyde and its salts (SALWAY, T., 1325; P., 192).

- I.O.N.** α -allyl derivative of pinene nitrosoazide (FORSTER and
STEWART, T., 249; P., 19).
- I.O.N.** Diethylmalonylethylmalonamide (REMFRY, T., 618).
- I.O.N.** Diethylmalonamide (REMFRY, T., 618).
- I.O.C.** Methyl trichloroacetate, preparation and rotation of (COHEN),
T., 1064.
- I.O.S.** Methyl ethylpropylsilcol (KIRPING and HACKFORD, T., 141).
- I.O.C.** Methyl dichloroacetate, preparation and rotation of (COHEN),
T., 1064.
- I.O.C.** Methyl monochloroacetate, preparation and rotation of (COHEN),
T., 1064.
- I.O.Br.** Methyl monobromoacetate, preparation and rotation of
(COHEN), T., 1064.
- I.O.I.** Methyl iodoacetate, preparation and rotation of (COHEN), T., 1064.
- I.O.N.** Methyl nitroacetate, preparation and rotation of (COHEN),
T., 1064.
- I.O.N.** α -Amino nonoylalanine (HOPWOOD and WEIZMANN), T., 1581.

24 III

- H₂O.N** Bisnitrobenzenediazo-azobenzene (GREEN and BEARDER), T.,
 651; P., 229.
H₂O.N Casimiroine, and its salts (POWER and CALLAN), T., 1996; P., 258.
H₂O.N Tetraethyl 1,6-nitrodiphenyl-3,4,3',4'-tetracarboxylate
 (GOSWAMY and HAMPSHIRE), T., 724.
H₂O.K β -Butyl hydrogen potassium phthalate (PICKARD and KEN-
 YON), T., 58.
H₂O.S Triphenetylsulphonium hydroxide, dichromate of (HILDITCH),
 T., 1699.
H₂O.N Diacetylusopogelsemine, and its hydrochloride (MOORE), T., 1236.
 Triacetylusopogelsemine, and its hydrochloride (MOORE), T., 1240.

24 IV

- $C_{22}H_{20}O_2N_2S$ β -Naphthaleneanilinosulphamoylaurylglycine (HARRIS and WEIZMANN), T., 573.
 $C_{22}H_{20}ONCl$ α - and p -Chlorostearanilide (KING and OXTON), T., 159.

 C_{25} Group.

- $C_{25}H_{42}O_2$ Methyl casimiroate (POWER and CALLAN), T., 266; P., 53.
 $C_{25}H_{42}O_2$ Withanilol (POWER and SALWAY), T., 497; P., 53.
 $C_{25}H_{42}N$ Pentadecyl- α - and β -naphthylamines, and their salts (LE SUEUR), T., 829, 832.

25 III

- $C_{25}H_{31}O_4N_2$ Dinitro- derivative of 5-dimethylaminoanilo-3:4-diphenylcyclopenten-1:2-dione (REHMANN and NAUNTON), P., 310.
 $C_{25}H_{31}O_4N_2$ 5-Dimethylaminoanilo-3:4-diphenylcyclopenten-1:2-dione. (REHMANN and NAUNTON), P., 309.

25 IV

- $C_{25}H_{31}O_4N_2Br_2$ Dibromo- derivative of 5-dimethylaminoanilo-3:4-diphenylcyclopenten-1:2-dione (REHMANN and NAUNTON), P., 310.
 $C_{25}H_{31}O_4N_2Br$ Bromo- derivative of 5-dimethylaminoanilo-3:4-diphenylcyclopenten-1:2-dione (REHMANN and NAUNTON), P., 310.
 $C_{25}H_{31}O_4N_2S$ Benzenesulphonylcinchonine and benzenesulphonylcinchonidine (HILDITCH, T., 239).

 C_{26} Group.

- $C_{26}H_{31}O_{14}$ Acetylcaeruleocephalic acid (PERKINS), T., 1443; P., 194.
 $C_{26}H_{29}N_4$ Phenylhydrazone of 2:2'-dialdehydodiphenyl (KINSMAN and TURNER), T., 2112.
 $C_{26}H_{37}O_4$ Acetylcaesimiroic acid (POWER and CALLAN), T., 265; P., 53.
 $C_{26}H_{40}O_4$ Diacetylbyronol (POWER and MOORE), T., 913; P., 118.

26 III

- $C_{26}H_{19}OS_2$ Thioxanthanyl oxide (HILDITCH and SMILES), T., 138; P., 1504.
 $C_{26}H_{27}O_2N_2$ Salicyldiphenylbenzamidine (THERLEY and HARRIS), T., 1504.
 $C_{26}H_{29}O_2N_2$ Benzoylcinchonine and benzoylcinchonidine (HARRIS), T., 239.
 $C_{26}H_{27}O_4N_2$ Di- α -carbethoxybutyrylbenzidine (REFFERT), T., 622.
 $C_{26}H_{29}O_2N$ α -1-Naphthylaminopalmitic acid (LE SUEUR), T., 829.
 α -2-Naphthylaminopalmitic acid (LE SUEUR), T., 829.

26 IV

- $C_{26}H_{19}O_2Cl_2S$ Dibenzoyl- p -chlorophenol α -sulphoxide (HARRIS and SMILES), T., 980.

 C_{27} Group.

- $C_{27}H_{29}N_2$ 1:2:4:5-Tetraphenylyglyoxaline, and its salts (EVEREST and MCGIBBIN), T., 1748; P., 209.
 $C_{27}H_{35}O_4$ Acetylwithanilol (POWER and SALWAY), T., 497.
 $C_{27}H_{35}N$ Heptadecyl- α - and β -naphthylamines, and their salts (LE SUEUR), T., 828; P., 104.

FORMULA INDEX.

27 II—31 III

- C₂₆ Group.**
C₂₆ H₄₄ N₂ O₂ Cholesterol, compounds of, with fatty acids (PARTINGTON), T., 313;
C₂₆ H₄₄ N₂ O₂ Cholesterol, from bryony root (POWER and MOORE), T., 942; P., 118.
C₂₆ H₄₄ N₂ O₂ Cholesterol from *Wulania somnifera* (POWER and SALWAY), T., 493; P., 53.

27 III

- C₂₇ H₄₄ N₂ O₂** 4-Keto-8-benzoylanilino-4,8-diphenylethane (EVEREST and MATTHEWS), T., 1748.
C₂₇ H₄₄ N₂ O₂ Methylammonium acid picraminobenzoates (CROCKER and MATTHEWS), T., 397; P., 22.
C₂₇ H₄₄ N₂ O₂ Guanidine acid *m*-picraminobenzoate (CROCKER and MATTHEWS), T., 310.

C₂₈ Group.

- C₂₈ H₄₄ N₂ O₂** 1,3-Ditolaquinhydrone (MOIR), P., 226.
C₂₈ H₄₄ N₂ O₂ Acetylotetrahydroxydiphenyl (PERKINS), T., 1447; P., 195.
C₂₈ H₄₄ N₂ O₂ 1,3-Ditolaquinhydrone diimine, and its salts (MOIR), P., 228.

28 III

- C₂₈ H₄₄ N₂ O₂** 5,5-Dibromo-4:4'-dibenzoyloxy-3:3'-ditolyl (MOIR), P., 227.
C₂₈ H₄₄ N₂ O₂ Dibromoditolaquinhydrone (MOIR), P., 227.
C₂₈ H₄₄ N₂ O₂ Ethylammonium acid picraminobenzoates (CROCKER and MATTHEWS), T., 397; P., 22.
C₂₈ H₄₄ N₂ O₂ 4,2-Naphthylaminostearic acid (LE STUR), T., 828.
C₂₈ H₄₄ N₂ O₂ Naphthylaminostearic acid (LE STUR), T., 831; P., 104.

28 IV

- C₂₈ H₄₄ N₂ O₂** Phenylthiophenyl diphenetylsulphonium chloride, platinum salt (HILLIOT), T., 1096.

C₂₉ Group.

- C₂₉ H₄₆ N₂ O₂** Hydrocarbon, from the oil of *Myrica gale*, L. (PICKER), T., 1766; P., 230.

29 II

- C₂₉ H₄₆ N₂ O₂** Dibenzoylchrysophanic acid (TUTTS and CLEWER), T., 956.

C₃₀ Group.

- C₃₀ H₄₈ N₂ O₂** Dibenzoylrhein, and its potassium salt (TUTTS and CLEWER), T., 952.
C₃₀ H₄₈ N₂ O₂ Dibenzoylmodin monomethyl ether (TUTTS and CLEWER), T., 951.
C₃₀ H₄₈ N₂ O₂ Withamic acid (POWER and SALWAY), T., 505; P., 53.

30 III

- C₃₀ H₄₈ N₂ O₂** Pentamethylquercetinazo- β -naphthol (WATSON), P., 165.
C₃₀ H₄₈ N₂ O₂ Dibenzylmethylsilyl oxide (KIPPING and HACKFORD), T., 162.

C₃₁ Group.

- C₃₁ H₅₀ N₂ O₂** Pyridine acid *o*-picraminobenzoate (CROCKER and MATTHEWS), T., 398.

31 IV

- $C_{27}H_{17}ON_2Cl$ 3:6-Dianilino-9-phenylxanthenyl chloride (POPE and HOWARD), T., 552.
 $C_{27}H_{17}O_2N_2Cl$ 3:6-Di-*p*-hydroxyphenylamino-9-phenylxanthenyl chloride (POPE and HOWARD), T., 553.
 $C_{28}H_{17}ON_2Cl_2$ 3:6-Dipaminophenylamino-9-phenylxanthenyl chloride (POPE and HOWARD), T., 553.
 $C_{21}H_{15}ONS$ Pentadecyl- α and β -naphthylbenzenesulphonamide (SZUKR), T., 830, 833.

 C_{32} Group.

- $C_{32}H_{40}O$ Somnirol (POWER and SALWAY), T., 502; P., 53.

32 III

- $C_{22}H_{17}O_2N_3$ Aniline acid *o*-picraminobenzoate (CROCKER and MATHIAS), T., 308.
 $C_{22}H_{15}N_3S$ Phenylhydrazone of dehydro- β -naphthol sulphide (HILDITCH and SMILES), T., 982.
 $C_{22}H_{17}O_2N_3$ Dianhydrodicotarnine-2:4:6-trinitro-*m*-xylene (HILTON and ROBINSON), T., 2131.

32 IV

- $C_{28}H_{19}O_4N_2S_2$ Diphenylbisazonaphthylaminesulphonic acid, *orange* (*Comp. red*), osmotic pressure and conductivity of aqueous solutions (CROCKER and HARRIS), T., 1554; P., 209.

 C_{33} Group.

- $C_{33}H_{40}O$ Somnitol (POWER and SALWAY), T., 504; P., 53.

33 III

- $C_{28}H_{19}ON_2$ Benzoyldianilinosilbene, and its salts (EVERETT and MATHIAS), T., 1758.
 $C_{28}H_{19}O_2N_3$ Dianhydrocotarninetrinitromesitylene (HILTON and ROBINSON), T., 2135.

33 IV

- $C_{28}H_{17}ON_2Cl$ 3:6-Di-*o*- and *p*-toluidino-9-phenylxanthenyl chloride (POPE and HOWARD), T., 552.
 $C_{28}H_{17}O_2NS$ Heptadecyl- α and β -naphthylbenzenesulphonamide (SZUKR), T., 829, 832.

 C_{34} Group.

- $C_{34}H_{40}O_4$ Acetylsomnirol (POWER and SALWAY), T., 508.

34 III

- $C_{30}H_{21}O_2S$ Dibenzoyl β -naphthol sulphide (HILDITCH and SMILES), T., 983.
 $C_{30}H_{21}O_2S$ Dibenzoyl β -naphthol sulphoxide (HILDITCH and SMILES), T., 983.

 C_{35} Group.

- $C_{35}H_{40}O_4$ Dibenzoyltrifolanol (SALWAY), T., 2155.
 $C_{35}H_{38}O$ Elaidone (EASTERFIELD and TAYLOR), T., 2306; P., 279.
 Oleone (EASTERFIELD and TAYLOR), T., 2303; P., 279.
 $C_{35}H_{37}O$ Dileptadecylcarbinol, and its acetate (EASTERFIELD and TAYLOR), T., 2301; P., 279.

35 III

- E_2ON Elaidoneoxime (EASTERFIELD and TAYLOR), T., 2306; P., 279.
 E_2ON Elaidoneoxime (EASTERFIELD and TAYLOR), T., 2305; P., 279.

C_{22} Group.

- E_2O Tribenzoylmodin (TUTIN and CLEWER), T., 953.
 E_2O Hexaphenylallicothane (KIPPING), P., 144.

C_{27} Group.

- L_2O Dibenzoylcalabarol (SALWAY), T., 2156; P., 273.
 L_2O Diacetylsomnitol (POWER and SALWAY), T., 504; P., 53.

C_{29} Group.

- L_2ON Compound, of benzyldianilinostilbene and picric acid (EVEREST and M. CHIEF), T., 1730.

39 IV

- L_2ONCl 6-Dibenzophenylamino-9-phenylxanthenyl chloride (POPE and H. WARD), T., 552.

C_{40} Group.

- E_2ON Dibenzoyldianilinostilbene, and its methiodide (EVEREST and M. CHIEF), T., 1735; P., 218.

C_{43} Group.

- E_2O Brassidone (EASTERFIELD and TAYLOR), T., 2306; P., 279.

43 III

- E_2ON Brassidoneoxime (EASTERFIELD and TAYLOR), T., 2305; P., 279.

C_{45} Group.

- E_2ON Compounds, of benzyldianilinostilbene with *o*- and *p*-nitrophenol (EVEREST and McCOMBIE), T., 1760.

C_{51} Group.

- E_2O Dipentecoylcarbinol, and its acetate (EASTERFIELD and TAYLOR), T., 2302; P., 279.

51 III

- E_2ON Compound, of benzyldianilinostilbene and phenol (EVEREST and McCOMBIE), T., 1760.
 E_2ON Cerotoneoxime (EASTERFIELD and TAYLOR), T., 2302; P., 279.

C_{55} Group.

- E_2O Montanone (EASTERFIELD and TAYLOR), T., 2302.

55 III

$C_{15}H_{21}ON$ Montanoneoxime (EASTFIELD and TAYLOR), T., 2362, p. 23

 C_{56} Group.

$C_{56}H_{88}O_4$ Benzoylcaerulicollagic acid (PERKIN), T., 1447, p. 14

 C_{59} Group.

Organic Chemistry.

Absorption of Hydrocarbon Gases by Non-aqueous Liquids.

S. J. S. JONES AND DANIEL (J. *Physical Chem.*, 1911, 15, 587-610).—The absorption of methane, ethane, and ethylene in ten organic liquids has been determined at a series of temperatures lying between 0° and 30°.

The gas burette and Ostwald absorption pipette were water-jacketed, and the temperatures were maintained approximately equal by means of a suitably proportioned resistance coil in each jacket, the jackets being in series. The gas in the burette was saturated with the solvent vapour and measured at the temperature of each experiment, so that no correction for vapour pressure of solvent was necessary. The solvents were boiled under diminished pressure, and precautions were adopted to remove dissolved air, the absence of which introduces considerable errors.

The solvents, in order of increasing absorptive power at 25° for methane, are methyl, amyl, ethyl, isopropyl alcohols, benzene, toluene, cyclohexane, hexane, heptane. With ethane and ethylene the solvents form a similar series, which, however, is quite unlike the order of solubility of these solvents for the less soluble gases nitrogen, carbon monoxide, carbon monoxide, and carbon dioxide.

It is suggested that the solubilities of the hydrocarbon gases are largely influenced by specific chemical relations with the solvents.

The absorption coefficient decreases in all cases as the temperature rises.
R. J. C.

Preparation of $\beta\gamma$ -Dimethyl- $\Delta^2\gamma$ -butadiene. BARD-CHIE ANILIN AND SCHUBERT (D.R.P. 235311).—A 70% yield of $\beta\gamma$ -dimethyl- $\Delta^2\gamma$ -butadiene can be obtained by heating pinacol or pinacol in at 400° with a dehydrating agent followed by fractional distillation of the product.
E. M. G. M.

Action of Diiodoacetylene on Organic Bases. WILLIAM M. BAYNE (J. Amer. Chem. Soc., 1911, 33, 1598-1601).—Diiodoacetylene was prepared in a yield of 80-90% of the theoretical by passing acetylene into a solution of potassium iodide and adding sodium hypochlorite solution drop by drop. On mixing solutions of diiodoacetylene and triethylamine in ether, the compound, $\text{NEt}_3 \cdot 2\text{C}_2\text{I}_2$, m. p. 115°, separates in feathery needles. Dipropylamine when treated in the same way yields the compound, $\text{NHP}_3 \cdot 2\text{C}_2\text{I}_2$, m. p. 160°, which forms long needles. By the action of acetylene chloride on phenylhydrazine, nitrogen is evolved and diophenylacetylene is produced, together with two phenylhydrazine hydriodides, $\text{C}_6\text{H}_5\text{NH} \cdot \text{NH}_2 \cdot \text{HI}$, m. p. 128° (decomp.), and $\text{NHPH} \cdot \text{NH}_2 \cdot \text{HI}$, which does not melt below 300°.
E. G.

Action of Alkaline Solutions on Trichlorinated Organic Compounds. G. BRESSANIN and E. SEGRE (*Gazzetta*, 1911, 41, 671—674).—Trichloroisopropyl alcohol (Mossler, *Abstr.*, 1909, 41), phenyltrichloromethylcarbinol (Jocitsch, *Chem. Zentr.*, 1907, 33), and chloroform (Mossler, *loc. cit.*) yield carbon monoxide when treated with alkalis. The authors find that acetonechloroform behaves similarly, and the amount of carbon monoxide evolved indicates that the substance decomposes chiefly according to the equation

$$\text{CCl}_3 \cdot \text{CMe}_2 \cdot \text{OH} = \text{COMe}_2 + \text{CHCl}_3.$$

Fusibility Curves of Gaseous Mixtures: Oxonium Systems Formed by Acetylene, Ethylene, Nitric Oxide, and Methyl Ether. GEORGES BACNE and ALBERT F. O. GERMANN (*Compt. rend.*, 1911, 153, 569—572. Compare this vol., i, 414; *ibid.*, 1910, 150, 118). The fusibility curve for methyl ether and acetylene shows a very marked maximum at -117.4° , corresponding with the compound $\text{Me}_2\text{C}(\text{O}^+\text{C}_2\text{H}_2)\text{Me}_2$. The existence of an analogous compound with ethylene is suggested by the occurrence of a maximum at -163.2° , but this is unstable in the liquid phase. The curve for methyl ether and nitric oxide shows a maximum at -156.3° , corresponding with an oxonium compound, which the constitution $\text{CH}_3\text{O}^+\text{C}_2\text{H}_4\text{NO}$ is ascribed.

Methyl ether has m. p. -138.4° .

W. G. B.

Primary Aliphatic Dinitro-, Nitro-nitrite, and Dialdehyde Compounds. JULIUS VON BRAUN and WLADISLAW SIEBER (*Ber.*, 1911, 44, 2526—2531).—It has been shown to be possible to apply V. Meyer's method of preparing nitro-compounds from alkylenes to dihalogen compounds which contain the halogen atoms at a distance from one another in the molecule. *aa*-Dinitrobutane, *aa*-nitropentane, and *aa*-dinitrodecane have been isolated and found to be stable substances. The nitro-nitrite compounds are considerably less stable.

On cautious reduction, the dinitro-compounds are converted into dioximes, hence affording a useful method of preparing α,α -dialdehydes.

aa-Di-iodobutane was allowed to react in ethereal solution with silver nitrite. From the product three fractions were isolated by distillation.

1. A small quantity of *butyl dinitrite*, $\text{NO} \cdot \text{O} \cdot (\text{CH}_2)_3 \cdot \text{O} \cdot \text{NO}$, b. p. $-105^\circ/15$ mm.

2. *Nitrobutyl nitrite*, $\text{NO}_2 \cdot (\text{CH}_2)_3 \cdot \text{O} \cdot \text{NO}$, b. p. about $116^\circ/15$ mm.; a liquid of ethereal odour, which soon began to decompose. On treatment with stannous chloride in hydrochloric acid solution, the compound yielded δ -hydroxybutylamine, b. p. $100^\circ/15$ mm. The dihydroxy derivative of the latter was found to melt at 75° , whereas Böttcher found 58° .

3. *aa*-Dinitrobutane is an almost colourless, practically odourless liquid of b. p. 176 — $178^\circ/13$ mm.; the sodium salt was analysed. Bromine transformed it into *aa* $\delta\delta$ -tetrabromo-*aa*-dinitrobutane, $\text{NO}_2 \cdot \text{CBr}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CBr}_2 \cdot \text{NO}_2$, m. p. 100° .

n-Pentane and silver nitrite gave a similar series of products. Anhydrous nitrite, b. p. 130—133°/15 mm., was found to be somewhat reduced. Reduction transformed it into *n*-hydroxyamylamine,

an oily liquid, b. p. 122°/16 mm., which forms an oily benzoyl derivative and a gold salt. The constitution of this compound was proved by conversion to piperidine by means of fuming hydriodic acid.

n-Pentane is an almost colorless liquid, b. p. 194—196°.

Its salts resemble those of α -dinitrobutane. The sodium salt, treated with benzenediazonium sulphate yields the compound $\text{N} \cdot \text{Ph} \cdot (\text{CH}_2)_5 \cdot \text{CH}(\text{NO}_2) \cdot \text{N} \cdot \text{Ph}$, m. p. 169°. *anti*-Tetra-*n*-pentene has m. p. 39°.

n-Tetradecane, $\text{C}_{14}\text{H}_{30}$, m. p. 49°, was obtained by similar methods. The tetrabromo derivative is an oil.

Oxidation with stannous chloride in hydrochloric acid solution, *n*-pentane gives glutardialdoxime, m. p. 178° (Harries, Abstr., 1901, 361, gives 171°); dinitrobutane gives succindialdoxime, and *n*-pentane furnishes *ax*-lipoicimideoxime, m. p. 137—141°.

H. W.

Anhydrous Formic Acid. JAMES B. GARNER, BLAIR SEXTON, and J. O. PARKER (*Amer. Chem. J.*, 1911, 40, 236—240).—Attention is drawn to the lack of agreement in the values given by previous investigators for the physical constants of formic acid. The methods employed hitherto employed yield only a 97—98% acid.

The anhydrous acid is best prepared by distilling the ordinary acid from anhydrous copper sulphate under a pressure of 120 mm. It has b. p. 8.5°, b. p. 56°/120 mm., 99.7°/741 mm.

The density and viscosity of the pure acid have been determined at temperatures varying from 10° to 40°: D_4^{10} 1.2260, D_4^{20} 1.2200.

F. B.

Soy Bean Oil. HERMANN MATTHES and A. DARLE (*Arch. Pharm.*, 1911, 240, 421—435. Compare this vol., i, 858).—The oil contains 80.4% of fatty acids in the form of glycerides. The fatty acids comprise palmitic 15%, oleic 56%, linoleic 19%, and linolenic 4.8% approximately (compare Lewkowitsch, *Oils, Fats, and Waxes*, 1909, 141, and Krimm, this vol., i, 766).

The two oils examined were "refined" and "unrefined," and gave the following constants respectively: D_4^{20} 0.9260 and 0.9265; solidification point -11.5° , -12° ; n_D^{20} 1.468, 1.468; $[\alpha]_D^{20}$ 0°, 0°; acid number 54.7, 171.3; saponification value 192.3, 194.3; Hehner number 67.2952; iodine value 131.3, 132.6; Reichert-Meissl value 3.42, 0.7543; Polensky number 0.7843, 1.0784. Both oils gave a rapid reaction. The two oils were exposed to (1) damp air, (2) dry damp oxygen, (4) damp oxygen during six months, and then examined. The results indicated that (1) moisture raised the acid number, (2) oxygen alone or in presence of moisture did not lower acid value, whilst (3) damp air reduced the iodine value from 131.3 to 122.5 and from 132.6 to 105.4 for the refined and unrefined respectively.

Farnsteiner's process applied to the mixed fatty acids gave a poor separation of palmitic acid, but the mixed unsaturated acids thus obtained still contained some saturated acid. Bremer's method gave a bad separation of saturated acid, but the mixed unsaturated acids obtained contained less palmitic acid than the product obtained by Farnsteiner's method. No separation of components of the mixed unsaturated acids could be effected by fractional distillation, and recourse was had to bromination, and a method is described for the successive separation of linolenic acid hexabromide, linoleic acid tetrabromide, and oleic acid dibromide from the mixture. I. A. H.

Preparation and Properties of α -Linolenic Acid from Linseed Oil. ERNST ERDMANN (*Zeitsch. physiol. Chem.*, 1907, 44, 179—197).—The acids obtained by the hydrolysis of linseed oil are freed from the solid acids at -18° in the presence of petroleum ether; the residual liquid acids are converted into their zinc salts by trituration with freshly precipitated basic zinc carbonate. By treating the salts with alcohol, the easily soluble zinc α -linolenate is removed, and from it pure α -linolenic acid obtained in 16–18% yield calculated on the liquid acids. The acid, the purity of which is controlled by its iodine number, 269–278, and by its quantitative conversion into the hexabromide, m. p. 179° , is an unstable, somewhat mobile liquid, D_4^{20} 0.9046 (after a few days, D_4^{20} 0.9248); the ester $(C_{18}H_{30}O_2)_2Zn \cdot \frac{1}{2}ZnO$, m. p. $72-73^\circ$, ammonium, barium, sodium, and basic copper salts are described. The acid yields trichloroacetic acid, $C_{18}H_{30}O_2Cl_3I_3$, m. p. 146° , with iodo chloride, and trichloroiodostearic acid, m. p. $124-126^\circ$, with iodine bromide, and is converted by ozone into an ozonide peroxide, $C_{18}H_{30}O_{12}$, which is decomposed by cold water, yielding hydrogen peroxide and a semi-solid mass, probably of the semialdehyde of azelaic acid and malonaldehyde.

The paper concludes with a reply to Rollett (this vol., i, 175). It is very questionable whether β -linolenic acid is present in the oil, although there is no doubt that it constitutes the chief ingredient of the mixture of acids obtained by the debromination of α -linolenic acid hexabromide. C. S.

Keto-enolic Tautomerism. III. Tautomerism of Ethyl Acetoacetate. KURT H. MEYER and PAUL KAPPELMAYER (*Ber.*, 1907, 44, 2718—2724).—Knorr, Rothe, and Auerbeck's general results on the desmotropy of ethyl acetoacetate (this vol., i, 516) confirm those obtained by K. H. Meyer (this vol., i, 350), but these authors find that, in a state of equilibrium, the ester contains 2% of the enolic form, whilst Meyer's results indicated 7.71%.

The authors have therefore investigated the sources of error in Meyer's method, namely, the necessity of adding a slight excess of bromine before a recognisable yellow colour is obtained, the conversion of ketonic into enolic form during the titration, and the possible presence in the alcoholic bromine solution of substances which liberate iodine from potassium iodide (such are really present in old but not in fresh solutions); but when allowance is made for a

these errors, the proportion of the enolic form is still found to exceed 7%.

The principal errors may be eliminated by adding to the solution, immediately after the bromine, alcoholic β -naphthol solution, which does not react with iodine, but does so very rapidly with bromine, forming a product unacted on by hydrogen iodide; the solution of the product in alcohol at -7° , and the addition of the alcoholic bromine and potassium iodide solutions need not occupy more than fifteen seconds. The amount of the ethyl acetate is then estimated by addition of potassium iodide and titration of the separated iodine with thiosulphate. By this method the presence of 7.4% of the enolic form is indicated. The difference between this and Knorr, Rothe, and Averbeck's value hence remains unexplained.

This titration method can only be employed where the bromine is added instantaneously to the ester, and where the transformation of the enolic form of the ester into the other is not too rapid.

The publication of Piccard's results (this vol., ii, 561) has led the author to apply the above method to the equilibrium of solutions of ethyl acetate in varying concentrations of ethyl acetoacetate in alcohol, benzene, carbon disulphide, and *n*-hexane. The surprising result was obtained that up to dilutions which can still be accurately investigated by the titration method, namely, $N/5$ to $N/10$, the proportion of the enolic form present continues to increase with the dilution, the equilibrium hence depending on the concentration. This is explained on the assumption that the solvent itself does not remain constant on dilution, but consists of a variable mixture of alcohol, etc., and the ester. Also, Dimroth (this vol., ii, 31) has shown that the equilibrium is dependent on the solubilities of the two components, and it may be that addition of the ester increases the solubility of the ketonic form and so increases its proportion.

For the four solvents named above, the curves connecting the logarithm of the concentration with the percentage of enolic compound and the ester apparently become perpendicular to the enolic axis at high dilutions, as though the equilibrium were then independent of the concentration, but the errors of the method are too great with dilute solutions to permit of this relation being definitely established.

T. H. P.

Keto-enolic Tautomerism. IV. Ferric Chloride Reaction of Enols. KURT H. MEYER (*Ber.*, 1911, 44, 2725—2729).—No quantitative measurements have been made of the velocity of enol-formation with ethyl acetoacetate, or of the quantity of enol-iron-compound formed with ferric chloride, but from their conductivity measurements Hantzsch and Desch (Abstr., 1902, i, 708) drew the conclusion that only very little enolate is present in an iron enolate solution of ethyl acetoacetate, in spite of the intensity of the colour. This conclusion is not confirmed by the author's results.

The estimation of enol in ethyl acetoacetate by titration with bromine (this vol., i, 350; preceding abstract) can be effected also in

presence of ferric chloride, the titration being continued until the violet colour of the enolate disappears. As the colour then returns again, owing to further enolisation, and can then be removed again by further addition of bromine water, and so on, the reaction serves as a striking lecture experiment. In order to avoid precipitation during the titration, this must be carried out as far as possible and at 0°.

Varying proportions of aqueous ethyl acetoacetate and ferric chloride solution were mixed, left at 0° for an hour so that equilibrium might be established, and titrated with N/10-bromine water. The results show that the ferric chloride exerts a direct enolising action, the quantity of enol formed varying with, but not proportionally to, the amount of ferric chloride added. The law of mass action leads to the equation: $C_{enolate} = K C_{aceto} C_{Fe} + K' C_{Fe} C_{aceto} C_H$, the quantity of enol formed being dependent on the number of hydrogen ions present. Indeed, the complex salt can be decomposed and the solution rendered acid by addition of acid. With low concentrations of the ferric chloride its hydrolysis, and hence the free acid present in it, may be neglected so that it can be assumed that, in a state of equilibrium, the proportions correspond with the hydrochloric acid liberated from the ferric chloride by the enol. Hence $C_{enolate} = K \sqrt{C_{FeCl_3} C_{HCl}}$. The values of this expression agree fairly well for low concentrations of ferric chloride, but vary considerably for the higher concentrations. It may be that in the latter case the free acid in the ferric chloride influences the equilibrium, and that with higher enol-forming powers which require larger amounts of bromine solution, the ferric hydrogen bromide destroys some of the enolate.

In alcoholic solution the quantity of enolate cannot be estimated accurately, owing to the change of colour on titration being quite distinct, but the colour of the enolate quickly re-appears, so that the velocity of conversion of keto- to enol-form is apparently considerably accelerated to a considerable extent.

That the slow formation of enolate is in reality due to the slowness of enolisation is shown by the fact that enolate formation is a unimolecular reaction, its course being quite analogous with that of enolisation by halogens (compare Lipworth, *Trans.*, 1904, 85). The velocity constant, $K = 0.017$ at 6°, shows that the catalytic action of ferric chloride is almost exactly as weak as that of free hydrochloric acid (this vol., i, 350). In alcoholic solution ferric chloride exerts a much more marked catalytic effect on enolisation. T. H. F.

Formation of Lævulic Acid from Glucosamine, Chitin, and Chitose. HEDWIG HAMBURGER (*Biochem. Zeitsch.*, 1911, 33, 1). —Lævulic and formic acids are produced when *D*-glucosamine, chitin or chitose are heated for four or five days with 25–50 per cent. sulphuric acid.

By treatment with sodium nitrite, glucosamine hydrochloride may be converted into chitose, and this when heated with hydrochloric acid also forms lævulic acid. These substances must therefore be included in those groups contained in the protein molecule which yield lævulic acid when hydrolysed with strong mineral acids. W. J. Y.

Walden Inversion. VII. Optically Active Leucic (Hydroxyhexoic) Acid and its Transformation into Bromoisohexoic Acid. HELMUTH SCHEIBLER and ALVIN S. WHEELER. *Bull.* 44, 2684—2690. Compare Abstr., 1911, i) —The resolution of hydroxyhexoic acid into its optically active components is accomplished by the crystallisation of its quinidine salt. Treatment with nitrous acid yields *l*-hydroxyisohexoic acid, the ethyl ester of which is converted by the action of bromine into ethyl *d*- α -bromoisohexoate. Since it has been shown by Fieser (Abstr., 1907, i, 194) that the *l*-bromo ester may be converted into the *l*-bromo-acid formed by the action of nitrosyl chloride in leucine, it is, therefore, possible to convert the latter into the ethyl ester of either *d*- or *l*- α -bromoisohexoic acid. The *l*-hydroxyisohexoic acid, prepared by the action of aqueous sodium hydroxide on α -bromoisohexoyl bromide, first at the ordinary temperature and then at 100°, crystallises in rhombic plates, m. p. 76–77° (Fieser, Abstr., 1908, i, 56; Gmelin, Abstr., 1893, i, 100). The ethyl ester has b. p. 80–81°/16 mm., and yields *ethyl isohexoate*, b. p. 86–87°/11 mm., when treated with sodium acetate and bromine. The resolution of the acid into its optically active components may be effected by means of the quinine or brucine salts, but most readily by crystallisation of the quinidine salt.

Isomeric isohexoic acid crystallises in thin prisms, m. p. 81–82°, and softens, sintering at 78°, and has, in *N*-sodium hydroxide solution, $[\alpha]_D^{25} = +0.2$, in water $[\alpha]_D^{25} = 10.4$ (± 0.2). It may also be converted by the action of nitrous acid in leucine, no appreciable change taking place during the transformation; the *barium* salt is obtained. The *d*-isomerite could not be obtained pure by the crystallisation of its alkaloidal salts, and is, therefore, best prepared by leucine and nitrous acid; in *N*-sodium hydroxide it has $[\alpha]_D^{25} = +0.2$.

Ethyl α -deoxyisohexoate, prepared by esterifying the *l*-acid with ethyl hydrogen chloride, has b. p. 79–80°/12 mm., $[\alpha]_D^{25} = 11.07^\circ$ (c. 2), $n_D^{20} = 1.465$, and is converted by treatment with phosphorus pentachloride into ethyl *d*- α -bromoisohexoate, considerable racemisation accompanying the action. F. B.

Lactarinic Acid and Ketostearic Acid Isolated from Fungi of the genus Lactarius. J. BOGGACULT and C. CHARAUX (*Compt. rend.* 1911, 153, 572–573*). Thörner's lactarinic acid has been obtained from *Lactarius theiogalus*, *L. plumbeus*, etc., but does not occur in spores. It is extracted by alcohol, and obtained as spangles, m. p. 57°, having the composition $C_{15}H_{31}O_5$. The substance appears to be a ketonic acid, since it yields an *acine*, m. p. 59–61°, which undergoes the Beckmann transformation, giving a *compound*, m. p. 61°. The ethyl ester has m. p. 41°. Reduction of the acid by means of sodium and alcohol leads to the formation of an *hydroxy-acid*, $C_{15}H_{31}O_6$; this substance yields an *acetyl* derivative, m. p. 52–53°, and furnishes stearic acid when its iodo-derivative is reduced with zinc dust and acetic acid. W. O. W.

* and *J. Pharm. Chim.*, 1911, [vii], 4, 337–343.

β -Butanolyglycuronic Acid. SUMIO SAKUYOSHI (*Indust. Ztg.* 1911, 36, 22-24).—Methyl ethyl ketone when given to rats by the mouth undergoes reduction in the body, and is excreted in the urine as a β -butanol derivative of glycuronic acid. This substance was isolated as the barium salt, $C_{10}H_{17}O_6Ba$, and from this substance did not reduce Fehling's solution directly, a glucosyl group was attributed to it.

Action of the Chlorides of Dibasic Fatty Acids on Ethyl Sodioacetoacetate. JOHANNES SCHEIBER (with P. L. S. 1911, 44, 2422-2429).—Chlorides of succinic, glutaric, and adipic acids react with ethyl sodioacetoacetate to form compounds of the type $[CH_2]_n[CO\cdot CH(COMe)\cdot CO_2Et]_n$. In addition, succinic acid reacts with 1 mol. of ethyl sodium acetoacetate, yielding *ethyl succinylacetoacetate*, $CO_2H\cdot CH_2\cdot CH_2\cdot CO\cdot CH(COMe)\cdot CO_2Et$. This corresponding malonic ester derivative (Scheiber, Abstr., 1909, 337) has a cyclic structure, but the succinyl ester shows no tendency to form a γ -lactone or other cyclic derivative.

Ethyl succinylacetoacetate crystallises in prisms, m. p. 52°. It gives a red coloration with alcoholic ferric chloride. With phenylhydrazine four products are obtained:

(a) The *phenylhydrazine* salt of *ethyl β -carbo-cytopropane-1,3-dicarboxylate*, *ethyl β -carbo-cytopropane-1,3-dicarboxylate-bis-phenylhydrazine*, m. p. 138°, forming colourless, unstable needles.

(b) A *pyrazole*, $C_{12}H_{15}O_4N_3$, the colourless crystals of which melt, m. p. 43°.

(c) A *bis*, $C_{14}H_{17}O_4N_3$ or $C_{12}H_{15}O_4N_4$, m. p. 157°.

(d) A *product*, m. p. 214-215°, soluble in alcohol.

With hydroxylamine an *isooxazole*, m. p. 81°, is obtained. With hydrazine the products are a *hydrazone*, m. p. 188°, and a *product*, m. p. 118°.

Ethyl succinyladipacetoacetate was obtained as an oil; it shows a cornflower-blue coloration with sulphuric acid changing to green.

Ethyl glutarylacetoacetate, $CH_2[CH_2\cdot CO\cdot CH(COMe)\cdot CO_2Et]_2$, is an oil of acid properties; with phenylhydrazine it gives *glutaryl acid-bis-phenylhydrazide*, $CH_2[CH_2\cdot CO\cdot NH\cdot NHPh]_2$, which crystallises in plates, m. p. 217-218°.

Ethyl adipyladipacetoacetate is also an oil; with phenylhydrazine *adipic acid-bis-phenylhydrazide*, $C_2H_4(CH_2\cdot CO\cdot NH\cdot NHPh)_2$, is obtained; it crystallises in nacreous, lustrous plates, m. p. 206-207°. E. L. A.

Preparation of Additive Compounds of Chloral with Amides. CHEMISCHE FABRIK GEDEON RICHTER (D.R.P. 23475).—When chloral is fused with a molecular proportion of an amide an additive compound is produced.

Bromoisovaleramide-chloral, $CHMe_2\cdot CHBr\cdot CO\cdot NH\cdot CO_2H$, forms small, colourless, odourless crystals with an intensely bitter taste and m. p. 116-118° (decomp.); it is insoluble in petroleum ether in water, but dissolves readily in other organic solvents, and of therapeutic value. F. M. G. M.

Phosphoric Acid Ester. A. VON LEDEDEFF (*Biochem. Zeitsch.*, 1911, 33, 248—260. Compare Abstr., 1910, i, 716; Young, *ibid.*, 1911, 33, 248). The author gives a short historical sketch of the rôle of phosphoric acid in alcoholic fermentation. A further investigation of phosphoric acid and phenomphenyl-hydrazones showed that the derivatives of hexose consist of one molecule of hexose to two molecules of phosphoric acid, in accordance with Young's suggested formula for the phosphoric ester of hexose, $C_6H_{11}O_5(PClO_3)_2$. The sodium and lead salts of the osazone of hexose were prepared and analysed, the full experimental method being given, and the formulæ given by the author two years ago are confirmed. The author claims that the possibility of ascribing the formula given by Young is due to his own investigations, and not to a suggestion by him of osazones and hydrazones. The paper is of considerable interest. S. B. S.

Preparation of Phosphoric Acid Esters of Carbohydrates and Polyols. CARL NEUBERG and E. KRETSCHMER (*Biochem. Zeitsch.*, 1911, 33, 5—14). Calcium d-galactophosphate, $C_6H_{11}O_5PCl_2 \cdot H_2O$, is obtained by slowly adding a solution of phosphoryl chloride in carbon tetrachloride to a suspension of calcium carbonate in water containing galactase, which is stirred continuously and cooled in a freezing mixture. The product is a white powder, which in solution in water reduces Fehling's solution and is fermented by beer-yeast. Lactose, when treated in the same manner, gave a product which contained a double salt of calcium lactulosephosphate and calcium chloride, from which the latter could not be removed. The compound was obtained, however, by partly hydrolysing calcium sucrosephosphate by heating for fifteen minutes with dilute hydrochloric acid. It is a white powder, which gives Seliwanoff's reaction for levulose, reduces Fehling's solution, and is readily fermented by yeast, thus differing from calcium dextrose-phosphate and sucrose-phosphate. It has the composition $C_{12}H_{21}O_{10}P_2Ca_2 \cdot H_2O$. Calcium glyceralphosphate was obtained in a similar manner to the galactophosphate. W. J. V.

Nature of the So-called Gallisin in Commercial Starch-syrup. JOS. GATTERBAUER (*Zeitsch. Nahr. Genussm.*, 1911, 22, 219—220). That portion of commercial starch-syrup which ferments very slowly and to which the name gallisin has been applied consists of a new carbohydrate, together with a small quantity of soluble dextrans are not present. This carbohydrate is termed glucosin provisionally, and is an isomeric of maltose, yielding only dextrose on hydrolysis. It may be separated from fermented starch-syrup as a viscous syrup, which, by treatment with a mixture of ethylphosphoric alcohol and ether, is converted into a white or yellowish-white powder. Beer-yeast ferments glucosin slowly, whilst yeast-glucosin and emulsin convert it into dextrose. Mineral acids and trypsin also convert glucosin into dextrose, but with high concentrations of mineral acids the reaction is reversible. The phenyl-osazone, m. p. 97—100°, is soluble in hot water and in alcohol; the phenylphenylosazone, m. p. 240°, is a red powder, which yields a

blue coloration when treated with sodium hydroxide. *Chlorobenzene* yields amorphous esters with benzoyl chloride, *p*-chlorobenzoyl chloride, *m*-nitrobenzoyl chloride, and benzenesulphonyl chloride. *Chlorobenzene* formed by the action of acids on dextrose in the manufacture of syrup (compare Alstr., 1905, i, 684).

Viscosity of Cellulose Solutions. HERMANN OST, *Zellulose-angew. Chem.*, 1911, 24, 1892—1896).—A number of determinations of the viscosity of cuprammonium solutions of various kinds of cellulose, such as cotton, wool-pulp, cotton-wool, filter paper, etc., have led the author to the conclusion that these viscosity determinations supply useful information on the nature and technical value of celluloses.

The cuprammonium solution employed was prepared by treating a solution containing 59 grams of copper sulphate with 100 c.c. of sodium hydroxide and dissolving the basic copper sulphate thus formed in ammonium hydroxide (D 0.900) to form one litre of solution. A certain quantity of cellulose was dissolved in this solution in a water-bath to give a solution containing one gram of the anhydrous cellulose in 50 c.c. The viscosity was determined by means of a special type of Ostwald's capillary viscometer.

It is found that previous treatment of the cellulose with bleaching agents produces a marked decrease in the viscosity of the cuprammonium cellulose solution; the same result is brought about also by heating the cellulose for about fifteen hours at 120–125°. On the other hand, treatment of the cellulose with a cold 5% solution of sodium hydroxide for about twenty-four hours, or with a cold 1% solution for one hour, does not affect the viscosity of the cuprammonium solution from which observation the conclusion is drawn that cotton linters do not undergo a chemical change during mercerisation. Sodium hydroxide, however, does act on cotton chemically, although very slowly; cotton which has been soaked in a 20% solution of sodium hydroxide, pressed, and kept in a stoppered bottle for several months, dissolves very readily in a cuprammonium solution and forms a solution of low viscosity.

Cuprammonium solutions of hydrocellulose, obtained by the action of dilute mineral acids on cellulose, are far less viscid than equivalent solutions of cellulose which have been acted on by bleaching agents.

W. H. C.

The Asymmetric Cobalt Atom. II. ALFRED WERNER, *Monatsh.*, 1911, 44, 2445—2455).—The author finds that compounds of the type $[A_2Coen_2]$, in which the two groups A are in the *cis*-position with respect to each other, can be resolved into two optically active isomerides, which is in accordance with the general formulæ of such compounds:

is quite different from that reported in the previous paper (this vol., i, 613). Compounds of the type $\left[\begin{smallmatrix} A \\ B \end{smallmatrix} \text{Co en}_2 \right]$ are tetrahedra, with four different groups (Co, A, B, and en), and are mirror images of each other, since the ethylenediamine groups are in different orientation in space in the two tetrahedra, one being in the same plane as A, and the other in the same plane as B. This is no longer the case with compounds of the type $\left[\begin{smallmatrix} A \\ B \end{smallmatrix} \text{Co en} \right]$, so that they cannot be said to contain an asymmetric centre, though the image and mirror image do not contain a plane of symmetry, but there occurs a kind of molecular asymmetry which may be regarded as *Molecular Asymmetry I*. It is of a simpler type than that occurring with carbon compounds, since there are only two groups, ethylenediamine and A, attached to the cobalt atom. Compounds which have been resolved belong to the 1:2-dinitro-*trans*-ethylenediamine series (the flavo-series), $\left[\begin{smallmatrix} (1) \text{O}_2\text{N} \\ (2) \text{O}_2\text{N} \end{smallmatrix} \text{Co en}_2 \right]$, and in

connection with their resolution, interesting analogies have been found with carbon compounds. When *d*-camphersulphonic acid is used, the least soluble salt is that of the *d*-radicle, ethylenediamine cobalt radicle is difficultly soluble, and that of the *l*-radicle is easily soluble. When *d*-bromocamphersulphonic acid is used, the least soluble salt is that formed with the *l*-radicle. These relations are just the reverse of those which obtain in the resolution of optically active carbon compounds, for example, in the resolution of tetrahydroquinadine.

Compounds of 1:2-dinitroethylenediaminecobalt salts show a very anomalous rotation dispersion, the *D* line being strongly rotated, whereas the *C* line is rotated to a very small extent or not at all. In solutions the following rotations were observed:

λ , μ	$[\alpha]_D$		$[\alpha]_C$	$[M]_D$
1.33	± 153	Bromide	1.325	± 151
1.34			1.34	
1.35	± 139	Nitrate	1.345	± 136
1.36			1.36	
1.37	± 111	Sulphate	1.375	± 113
1.385			1.38	

λ , μ	$[\alpha]_D$	<i>l</i> -Flavo- <i>trans</i> -sulphonate	16	-80.32
1.33	-66			

great differences exist in the solubilities of the active and inactive salts, as shown by the following table, where the solubilities are expressed in terms of grams of salt in 100 c.c. of water:

Salt	Isomer	<i>d</i> -Isomeric, <i>l</i> -Isomeric	Resonance	1:6-Di-nitro-
Bromide	1.33	4.36	1.17	2.202
Nitrate	1.33	6.49	0.16	2.652
Sulphate	1.33	1.63	1.71	2.55

Compounds of the formula $\left[\begin{smallmatrix} A \\ B \end{smallmatrix} \text{Co en}_2 \right]$, in which the A-radicles are

isomerism, and in proof of this it was not found possible to resolve the salts of the 1:6-dinitrodiethylenediaminecobalt-series into enantiomers.

The cases of isomerism which have been proved to exist in the diacido-diethylenediaminecobalt-salts may be summarised as follows:

(1) *Cis trans*-isomerism:

(2) Salt isomerism:

and also the 1:6-dinitrodiethylenediaminecobalt salts may be croceo salts.

(3) Ionisation metamerism:

X can be either Cl, Br, or SCN, etc.

(4) Co-ordination polymerism:

(5) Mirror image isomerism:

The inactive 1:2 dinitrodiethylenediaminecobalt salts (see Abstr., 1901, i, 511) are best obtained by heating together 20 grams of potassium cobaltinitrite and 48 grams of 10% ethylenediamine. The mixture begins to froth. The dark brown solution is filtered from unchanged cobaltinitrite, and on keeping deposits brilliant yellow crystals of the 1:2-dinitronitrite. The mother liquor, on evaporating, gives at first a further quantity of the salt, and then a mixture of the 1:2- and 1:6-dinitro salts which can be separated by fractional crystallisation. The iodide is obtained by heating the hot solution with sodium iodide.

In the resolution of the iodide by means of silver *d*-camphorsulphonate, a precipitate of a mixture of silver iodide and 1:2-dinitrodiethylenediaminecobalt *d*-camphorsulphonate is first obtained from the hot solution, from which mixture the camphorsulphonate may be extracted with hot water. The mother liquor from the mixture deposits a partial racemate on cooling, from which further quantities of the *l*-salt can be obtained by appropriate treatment (recrystallisation, etc.). When about 20 grams of the *l* salt have been obtained, the mother liquors are united, the iodide precipitated, and then treated with silver *d*-bromecamphorsulphonate. After collecting the silver iodide, the hot solution, on cooling, deposits brown needles of *d*-dinitrodiethylenediaminecobalt *d*-bromecamphorsulphonate.

To prepare the various active salts, the camphor- and bromo-camphor-sulphonates were precipitated with excess of sodium iodide, the resulting suspension of the iodide transformed into the base by treatment with silver oxide, and the salts then obtained by neutralisation of the base with the respective acids.

The active and inactive *1-dinitrodiethylenediaminecobalt chlorides*, YCl , where $\text{Y} = \left[\begin{array}{c} \text{O} \quad \text{N} \\ \diagup \quad \diagdown \\ \text{Co} \quad \text{en}_2 \end{array} \right]$, form brownish yellow, columnar crystals. The inactive salt is deep brown in colour, and crystallises in broad, thick plates. The *inactive bromides*, YBr , are similar in colour and shape to the inactive chlorides. The *active iodides*, YI , give well-developed octahedral prisms, whereas the inactive salt is microcrystalline and of prismatic habit.

The *active nitrates*, YNO_3 , form stout, prismatic or columnar crystals, distinguished from the long prisms of the inactive compound. The *inactive sulphates*, Y_2SO_4 , give flat prisms or tablets, whilst the *active salt* forms long, silky, light yellow crystals. The *active carbonates*, YCO_3 , crystallise in aggregates of short, stout prisms or tablets, whilst the *inactive salt* gives rhombic leaflets of amber-yellow tint.

1. 2-Dinitrodiethylenediaminecobalt d-camphorsulphonate, $\text{Y}(\text{O}_3\text{S}\cdot\text{C}_{10}\text{H}_{15}\text{O})_2$, m.p. 142–143°, pointed, golden-yellow crystals, d. 1:2. *Dinitrodiethylenediaminecobalt d-bromocamphorsulphonate*, $\text{Y}(\text{O}_3\text{S}\cdot\text{C}_{10}\text{H}_{15}\text{OBr})_2$, m.p. 141°, centimetre-long, brownish yellow prisms. 1:6 *Dinitrodiethylenediaminecobalt d-camphorsulphonate*,

m.p. 151°, amber-yellow or brownish yellow prisms, which are often centimetre long, $[\text{M}]_D^{25} + 45.2 - 47.7$. T. S. P.

Preparation of Mercury Derivatives of Alkali Alkyldithio-carbamic Acetates. LES ÉTABLISSEMENTS POULENC FRÈRES and SOCIÉTÉ GÉNÉRALE (U.R.P. 235356. Compare Abstr., 1907, i, 594).—*1-Ethylthio- α -aminooacetate*,

b.p. m.p. 70–71°, is prepared by slowly treating a cooled solution of *propylthioacetate*, $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{NHMe}$ (60 parts), in anhydrous ether with carbon disulphide (25 parts) in the same solvent. An exothermic reaction takes place; an oil separates which rapidly solidifies, is purified by crystallisation from ether or acetone. The *mercury compound*, $(\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{NMe}\cdot\text{CS}\cdot\text{S})_2\text{Hg}$, a pale yellow powder, is obtained when the foregoing compound is treated with a saturated solution of mercuric chloride, and this, when slowly treated with a 30% solution of sodium hydroxide (containing 2 mols. NaOH), yields a yellow precipitate of the *mercury sodium* double salt,

which is isolated in the form of a yellow powder. If the solution of the mercury sodium salt be heated until it darkens, a compound, $\text{Na}\cdot\text{CH}_2\cdot\text{NMe}\cdot\text{CS}\cdot\text{S}\cdot\text{Hg}\cdot\text{S}\cdot\text{CH}_2\cdot\text{CO}_2\text{Na}$, is obtained as a green powder.

F. M. G. M.

Preparation of Optically Active Polypeptides from Racemic Compounds. EMIL ABERHALDEN and HEINRICH FISCHER (*Zeitsch. physiol. Chem.*, 1911, 74, 394—408).—As a general rule, the enzymes of the ferments only hydrolyse those polypeptides which are composed of amino-acids which occur naturally. An exception is *dl*-leucyl-*l*-tryptophan, which, according to Hans Fischer (*ibid.*, 1911, 22, 599), is hydrolysed by the liver and by pancreatic juice. ABERHALDEN and SCHULER (Abstr., 1910, i, 304) have pointed out that the observed racemisation in the preparation of an optically active polypeptide must be considered the hydrolysis observed by Fischer to be due to the presence of *l*-tryptophan. The action of pressed yeast juice on *dl*-leucyl-*l*-tryptophan indicates that only *l*-leucyl-*l*-tryptophan is hydrolysed by the enzyme; the racemic compound *dl*-leucyl-*l*-tryptophan, and *d*-leucyl-*l*-tryptophan; *d*-leucyl-*l*-tryptophan when pure is not attacked.

It is possible by means of enzymes to obtain optically active polypeptides from racemic compounds; these are the optically active natural compounds, but a comparison of the magnitude of the optical power is possible.

Prepared by the action of yeast juice in aqueous solution, *d*-leucylglycine has $[\alpha]_D^{20} -87.87^\circ$ to -88.5° , and *l*-leucylglycine $[\alpha]_D^{20} +37.62^\circ$ to $+37.1^\circ$, in both cases somewhat higher than those obtained by Fischer for the optical antipodes.

Remarks on Henze's Paper on the History of Iodine in Organic Acid. ADOLF OSWALD (*Zeitsch. physiol. Chem.*, 1911, 74, 394—408). Compare this vol., i, 617). Certain misstatements in Henze's paper are corrected.

Methylated Guanidines. MARTIN SCHENCK (*Arch. Pharm.*, 1911, 240, 463—480. Compare Abstr., 1910, i, 99, 545, 546). The first part of this paper describes attempts to prepare α -methylguanidine, $\text{NMe}\cdot\text{C}(\text{NH}_2)_2$, the second, efforts to obtain $\alpha\beta$ -dimethylguanidine, $\text{NMe}\cdot\text{C}(\text{NH}_2)\cdot\text{NHMe}$, and the third gives an account of the properties of some new methylated guanidines and substances related thereto. The failure to obtain α -methyl- and $\alpha\beta$ -dimethyl-guanidines is due to the tendency these substances have to transform immediately into β -methyl- and α -dimethyl-guanidines respectively.

By the interaction of thiocarbamide and methylamine in presence of mercuric oxide, β -methylguanidine and dicyanodiamide are formed; the first probably by the action of cyanamide, first formed on the reaction. Ethyl iminocarbonate furnishes with methylamine, $\beta\beta$ -dimethylguanidine; with dimethylamine, $\alpha\alpha$ -dimethylthiocarbamide; with $\text{B}_2\text{H}_3\text{AuCl}_4$, m. p. 105° ; platinumchloride, $\text{B}_2\text{H}_3\text{PtCl}_6\cdot 2\text{H}_2\text{O}$ (m. p. anhydrous), and with ammonia, guanidine. Ethyl iminocarbonate appears to undergo methylation when left fourteen days in contact with methyl iodide and potassium hydroxide solution, since the product reacts with methylamine to form $\alpha\beta\beta$ -trimethylguanidine, with dimethylamine to form a substance giving a crystalline anhydrous $\text{C}_{15}\text{H}_{20}\text{O}_2\text{N}_4\text{Au}_2\text{Cl}_8$, m. p. 250 — 252° , and with ammonia in alcohol to form β -methylguanidine (I). With ammonia in one case a crystalline

of guanidine was obtained, indicating the presence of uncombined ether in the material used. Ethyl methyliminodithiocarbamate, $\text{NMe}(\text{SMe})_2$, gives with methylamine in alcohol, $\alpha\beta\beta'$ -trimethylguanidine, with ammonia in alcohol, β -methylguanidine, and with dimethylamine a substance yielding a cry-stalline aurichloride, m.p. below 100° .

For the preparation of $\alpha\beta$ -dimethylguanidine, $\text{NMe}(\text{C}(\text{NHMe})\cdot\text{NH}_2)$, various methods were tried unsuccessfully: Dimethylthiocarbamate reacted with ammonia in alcohol in presence of mercuric oxide to form $\alpha\beta$ -trimethylguanidine with some $\beta\beta'$ -dimethylguanidine (compare Chem. Abstr., 1893, i, 297). Dimethylethyl ϕ -thiocarbamide, $\text{NMe}(\text{SMe})\cdot\text{SEt}$, in the form of its *ethiolide*, m. p. 100° (approx.), reacts with ammonia in alcohol $\beta\beta'$ -dimethylguanidine (compare Noth, *Monatsh.*, 1241), and the same substance was obtained by the action of ammonia on $\alpha\beta\beta'$ -trimethyl ϕ -thiocarbamide.

$\alpha\beta\beta'$ -Trimethylguanidine aurichloride, $\text{NH}(\text{C}(\text{NHMe})\cdot\text{NMe}_2)_3\text{HAuCl}_4$, is obtained by the addition of gold chloride to the product of the interaction of methylthiocarbamide methiodide (p. 135) and dimethylamine in alcohol, forms small needles, readily soluble in water.

$\alpha\beta\beta'$ -Trimethylthiocarbamide methiodide, m. p. $210-212^\circ$, obtained by recombination of its two components in alcohol, gives an aurichloride, $(\text{C}(\text{NHMe})_2\text{CH}_2\text{Cl})_3\text{AuCl}_3$, m. p. 122° (approx.), on treatment with silver chloride and then with gold chloride. The similarly obtained $\beta\beta'$ -di-aurichloride has m. p. $192-194^\circ$. The methiodide reacts with dimethylamine in alcohol to form $\alpha\beta\beta'$ -trimethylguanidine, which is regenerated by the action of methylamine on the corresponding methiodide. The free trimethyl ϕ -thiocarbamide regenerated from the aurichloride gives with ammonia in alcohol, as stated above, $\beta\beta'$ -dimethylguanidine, and with dimethylamine, $\alpha\beta\beta\beta'$ -tetramethylguanidine, which the aurichloride has m.p. 117° (approx.). T. A. H.

Melamine from Hydrazine Salt and Dicyanodiamide.

By A. HOFMANN and OSKAR EHRHART (*Ber.*, 1911, **44**, 1717). Amitoguanidine nitrate may be easily and cheaply prepared from "Nitrolime" (50% calcium cyanamide) and hydrazine hydrate.

When heated with hydrazine or one of its salts, dicyanodiamide (meloguanidine) yields a series of hydrazine derivatives, among them *melamine*, $(\text{C}_2\text{H}_4\text{N}_4)_n(\text{NH}\cdot\text{NH})_m\cdot\text{H}_2\text{O}$, distinguished by its ability to take up oxygen in alkaline solution, giving an intensely bluish-violet oxidized matter. The *hydrochloride*, $\text{C}_6\text{H}_8\text{N}_6\cdot\text{HCl}$, dissolves in hot water giving a colloidal solution. The azine exhibits only slight oxidizing capacity, as water effects partial hydrolysis and ammonia liberates the base. It is very stable towards strong acids; when heated with fuming hydrochloric acid for twenty-four hours at 170° , it is slowly converted into carbon dioxide, ammonium chloride, and pyrimidine hydrochloride, whilst with fuming sulphuric acid at 190° it is slowly decomposed, giving principallyammelide (melanurenic acid). Nitro-hydrochloric acid also attacks it slowly, givingammelne nitrate. With excess of alkaline permanganate solution, it yields four

atoms of nitrogen per molecule, and, if the reaction is carried to the end on the water-bath, the hydrazine groups are burnt away and the cyanamide part of the molecule loses part of it. Ammelinamide yields substances of the ammeline ammelide group.

The bluish violet coloration formed when an alkaline solution of the azine is left exposed to the air is visible even after it has been diluted 100,000 parts of water. Reducing agents, such as hydrazine, azine, hydrazine, hyposulphite, and zinc dust, decolorise the solution, but the colour soon returns in the air. On acidification the alkaline solution becomes wine-red and then colourless, with the formation of transparent, flocculent matter.

The colouring matter can be fixed on unmodified tissue by soaking the tissue with the alkaline solution and then dipping in a chloride solution; the violet colour is changed to red by treatment with acetic acid. The colouring matter was isolated as a black powder, $(C_6H_4O_2N_4)_2Ba$, in the form of an opaque, violet-black powder with a bronzy lustre; the thallium salt, $(C_6H_4O_2N_4)_2Tl_2H$, was also prepared.

In concentrated sulphuric acid melamazine gives with a little nitrate an intense yellowish-red coloration, which remains on heating; the bromine reaction, and on warming turns to blue and then black, with evolution of gas. Hydrogen peroxide in concentrated sulphuric acid also gives a transitory reddish-yellow coloration, while the acid yields a deep reddish-brown colour, changing to black with evolution of gas, on heating.

Prussian Blue and Turnbull's Blue. III. FRIEDRICH W. AND, in part, G. WEGELIN, FRIEDRICH P. TREADWELL, and G. DIEFENTHAUER [*J. pr. Chem.*, 1911, [ii], **84**, 353—369. Compare *ibid.*, 1909, i, 142, 705]. The composition of the precipitates obtained by mixing (0.1 molar) solutions of hydroferrocyanic acid and ferric chloride and of hydroferricyanic acid and ferrous chloride, as well as investigated by methods similar to those already described in experiments on the composition of the precipitates formed from potassium ferrocyanide and ferric chloride and from potassium ferricyanide and ferrous chloride have been repeated, with results very somewhat from those previously given.

The precipitates obtained by mixing potassium ferrocyanide and ferric chloride consist of $Fe_4^{III}[Fe(CN)_6]_3^{IV}$ only when the ratio $K_4[Fe(CN)_6]/FeCl_3 (=x) < 0.75$. When x lies between 0.75 and 1 the precipitate consists of a mixture of $Fe_4^{III}[Fe(CN)_6]_3^{IV}$ and $K_2Fe^{III}[Fe(CN)_6]_3^{IV}$, whilst as x becomes greater than 0.75 the nature of these compounds with gradually increasing amounts of $K_2Fe^{III}[Fe(CN)_6]_3^{IV}$ is produced.

With hydroferricyanic acid and ferric chloride, when the ratio $H_4[Fe(CN)_6]/FeCl_3 (=y) < 0.75$, the precipitate has the composition $Fe_4^{III}[Fe(CN)_6]_3^{IV}$. For values of y between 0.75 and 0.85 the precipitate consists of the latter compound mixed with $2Fe_2^{III}[Fe(CN)_6]_3^{IV}$. When $y > 0.85$ the precipitate consists of a mixture of these compounds with $Fe_2^{III}[Fe(CN)_6]_3^{IV}$.

In the case of potassium ferricyanide and ferrous chloride, when the ratio $H_3[Fe(CN)_6]/FeCl_2 (=z) < 0.714$, $KFe_2^{III}[Fe(CN)_6]_3^{IV}$

For values of z lying between 0.714 and 0.75, this is accompanied by $KFe_2Fe_3[Fe(CN)_6]_2$. When z varies from 0.75 to 1, the precipitate consists of a mixture of $KFe_2Fe_3[Fe(CN)_6]_2$ and $KFe_4[Fe(CN)_6]$, whilst for values of $z > 0.9$, the two latter compounds are accompanied by $Fe_4[Fe(CN)_6]$, produced according to the equation $4KFe_2[Fe(CN)_6] = Fe_4[Fe(CN)_6] + K_4[Fe(CN)_6]$. Similar results were obtained in the case of ferrous chloride and hydrocyanic acid. When the ratio $H_2[Fe(CN)_6] : FeCl_2 < 0.75$, the precipitate consists of a mixture of $HFe_2Fe_3[Fe(CN)_6]_2$ and $HFe_4[Fe(CN)_6]$; if the ratio > 0.78 , a mixture of the latter compound with $HFe_2Fe_3[Fe(CN)_6]_2$ and $Fe_4[Fe(CN)_6]$ is produced.

Reaction of Hydrazine. VI. Reaction between Mercuric Oxide and Hydrazine Hydrate in Alcoholic Solution. C. F. F. N. SEZ (*J. Amer. Chem. Soc.*, 1911, 33, 1555—1563).—The authors (shortly (Abstr., 1909, ii, 658) have shown that when an alcoholic solution of hydrazine sulphate is heated with either yellow or red mercuric oxide, neither ammonia nor azoimide is produced, but that when yellow oxide is added gradually to a slightly alkaline solution of hydrazine, both ammonia and azoimide are formed in appreciable amounts.

A further study has now been made of the action of mercuric oxide on an alcoholic solution of hydrazine hydrate, and it has been found that at ordinary temperature the reaction proceeds in accordance with the equation $N_2H_4 \cdot H_2O + 2HgO = N_2 + 2Hg + 3H_2O$. The amount of nitrogen actually obtained was slightly less than that required by the equation. Neither ammonia nor azoimide was produced, but products were obtained of the formation of ethylenediazine. Mercury diethyl was also found to be a product of the reaction, together with a white, waxy, solid compound containing carbon, hydrogen, and about 55% of mercury. The latter substance has a strong odour, resembling that of garlic, does not show a definite reaction when applied to the skin produces painful and slow-healing sores. The same compound is slowly produced by the action of ethylenediazine on mercury diethyl.

E. G.

The Constitution of Aliphatic Diazo-compounds and of Azoimide. JOHANNES THIELE (*Ber.*, 1911, 44, 2522—2525).—A theoretical paper in which arguments are brought forward in favour of the following formulae for certain products of the action of hydrazine on aldehydes and of the formula $HN=N:N$ for azoimide.

H. W.

Tetra-alkylsilicanes. ARTUR BYGÉN (*Ber.*, 1911, 44, 2640—2652).—After a close examination of the action of magnesium alkyl halides on silicon tetrachloride shows that the monoalkyl derivatives, $SiRCl_3$ where R is ethyl, propyl, butyl, isobutyl, or isopentyl, and tetra-alkylsilicanes, are obtained with comparative ease, but the separation of the mono- and trialkyl derivatives presents great difficulties, and these compounds have not been obtained pure. Magnesium methyl bromide is a more efficient reagent than the iodide, and by its means tetra-methylsilane, b. p. 26—27°, is easily obtained.

Voll. C. I.

The following substances have been prepared by the usual Grignard reaction; the desired product is finally separated from its ethereal solution by treatment with concentrated sulphuric acid, in which it dissolves, leaving the desired product, which is removed by distillation. *Trimethylpropylsilicane*, SiMe_2Pr , b. p. 89.5° (corr.), D_4^{20} 0.7063, from trichloropropylsilicane and magnesium methyl bromide (3.3 mols.); *dimethyldiethylsilicane*, SiMe_2Et_2 , b. p. 95.8° (corr.), D_4^{20} 0.7214, from dichlorodiethylsilicane and magnesium methyl iodide (2.5 mols.); *trimethylbutylsilicane*, h. p. 115.1° (corr.), D_4^{20} 0.7227, from trichlorobutylsilicane and magnesium methyl bromide (3.2 mols.); *dimethylethylpropylsilicane*, b. p. 121.0° (corr.), D_4^{20} 0.7347, from dichloroethylpropylsilicane and magnesium methyl bromide (2.3 mols.); *trimethylisopropylsilicane*, b. p. 131.5° (corr.), D_4^{20} 0.7322, from trichloroisopropylsilicane and magnesium methyl bromide (3.2 mols.); *dimethylethylbutylsilicane*, h. p. 138.0° (corr.), D_4^{20} 0.7463, from dichloroethylbutylsilicane and magnesium methyl bromide (2.3 mols.).

Tetra-ethylsilicane has b. p. 153.0° (corr.), and D_4^{20} 0.7694.

The preceding tetra-alkylsilicanes have an odour of petroleum, are almost unattacked by concentrated sulphuric acid or alkalis, are oxidised by concentrated nitric acid at a high temperature, react with chlorine in the cold and with bromine by warming, and explode when their mixture with air or oxygen is heated. The h. p. is lower and the molecular volume (of isomerides) is greater, the larger is the number of methyl groups directly attached to the silicon atom.

The new chlorosilicanes required in the preceding syntheses are *trichlorobutylsilicane*, $\text{C}_4\text{H}_9\cdot\text{SiCl}_3$, b. p. $148.5\text{--}149.5^\circ$, D_4^{20} 1.169, from magnesium butyl bromide and silicon tetrachloride; *trichloroisobutylsilicane*, h. p. $138\text{--}143^\circ$, D_4^{20} 1.161, prepared like the preceding compound; *dichloroethylpropylsilicane*, b. p. $152\text{--}158^\circ$, D_4^{20} 1.045, from trichloropropylsilicane and magnesium ethyl bromide; *dichloroethylisobutylsilicane*, b. p. $165\text{--}174^\circ$, from trichloroisobutylsilicane and magnesium ethyl bromide. C. S.

Organo-metallic Ester Compounds. I. Iodostanni-ester Compounds. BRUNO EMMERT and WILHELM ELLER (*Ber.*, 1911, 44, 2328—2330).—Tin reacts with ethyl iodoacetate in presence of iodine to form ethyl di-iodostanni-diacetate, $\text{SnI}_2(\text{CH}_3\cdot\text{CO}_2\text{Et})_2$. Compounds of this type differ from the alkyl compounds of the metals in being completely decomposed by water and alkalis, thus:

They appear to yield salts when treated with silver nitrate or sulphate, but so far these have not been separated from their decomposition products. Treated with the Grignard reagent they give the corresponding tin tetra-alkyls.

Ethyl di-iodostanni-diacetate, m. p. 101.5° (corr.), crystallises from carbon tetrachloride on addition of ether in colourless, odourless needles. It is decomposed by baryta into ethyl acetate, stannic oxide and hydriodic acid. With magnesium phenyl bromide and magnesium ethyl bromide, it gives tin tetraphenyl and tin tetraethyl respectively.

Ethyl di-iodostanni-di-o-benzoate, obtained by heating ethyl iodo-

permanganate (5 grams), tin foil (1.2 grams), and a little iodine, in a closed tube during five days at 150°, crystallises in grayish-yellow, microscopic needles, and is practically insoluble in all solvents. T. A. H.

$\Delta^{1,2}$ -Dihydrobenzene [$\Delta^{1,2}$ -cyclohexadiene]. NICOLAI ZELINSKY and ALEXANDER GORSKY (*Ber.*, 1911, 44, 2312—2316*).—Doubts have been expressed by Brühl (Abstr., 1908, ii, 1002) and by Harries and Szplawa-Neyman (Abstr., 1909, i, 218) as to the accuracy of the data published by the authors regarding $\Delta^{1,2}$ -cyclohexadiene (Abstr., 1908, i, 619, 722), the latter suggesting that the apparent absence of optical exaltation in this hydrocarbon, in spite of the presence of conjugated double linkings, was due to the occurrence of cyclohexene in the material examined. The authors find that when quinoline reacts with 1:2-dibromocyclohexane, the products obtained depend on the relative quantities used and the method of mixing. When the dibromide is added drop by drop to quinoline in excess, the product is a mixture of cyclohexadiene and cyclohexene, but the material they originally worked with could not have contained more than a trace of cyclohexene. Further, determinations of the molecular refractions of mixtures of $\Delta^{1,2}$ -dihydro-*m*-xylene (Klages, Abstr., 1907, i, 597) with 1:3-dimethylcyclohexene (Abstr., 1902, i, 2) show that the latter does not mask the optical exaltation of the former to any considerable extent. Moreover, the ultra-violet absorption spectra of the two cyclohexadienes examined by the authors (*loc. cit.*) are normal and similar, indicating that the hydrocarbon now under discussion is homogeneous.

Bromo- Δ^1 -cyclohexene, b. p. 164—166°, or 69°/35 mm., D_4^{20} 1.3901, n_D^{20} 1.5134, obtained as a by-product in the action of quinoline on 1:2-dibromocyclohexane, combines with bromine to form a dibromide, b. p. 138—140°/16 mm., and is oxidised by permanganate to adipic acid.

$\Delta^{1,2}$ -cyclohexadiene combines with hydrogen bromide to form a dibromide, b. p. 80—85°/39 mm. This combines with bromine to form a tribromide, b. p. 150°/15 mm., and is oxidised by permanganate to a dibasic hydroxy-acid, $C_6H_{10}O_5$, m. p. 93—94°, which distils almost unchanged at 240°/20 mm. The formation of this dibasic hydroxy-acid on oxidation renders improbable the constitution assigned to this dibromide by Crossley (*Trans.*, 1904, 85, 1422). T. A. H.

Tetramethylcycloheptatriene. HANS RUPE and W. KREKOVIC (*Ber.*, 1911, 44, 2702—2713).—The action of magnesium methyl iodide on eucaryone yields a tetramethylcycloheptatriene,

which is a tetramethyl derivative of the cycloheptatriene prepared by Wlenburg (Abstr., 1883, 670) and Willstätter (Abstr., 1901, i, 223, 49). In one instance the corresponding tertiary alcohol, b. p. 107°/11 mm., was also obtained, but this could not be obtained pure, as it undergoes partial decomposition on distillation with formation of the tetramethylcycloheptatriene. Further, a slight variation in the method of preparing the latter results in its admixture with

* and *J. Russ. Phys. Chem. Soc.*, 1911, 43, 1102—1107.

two dimeric, isomeric methyl derivatives of dihydroeucarvone ($C_{11}H_{18}O$),

Tetramethylcycloheptatriene, $C_{11}H_{18}$, is a colourless, mobile oil, b. p. 67–68°/11 mm., D^{20}_D 0.8687, n^{20}_D 1.50660. The optical exaltation (compare Auwers and Eisenlohr, Abstr., 1910, ii, 365, 367), +0.9, is exactly what is observed for a pair of conjugated ethylene linkings with a side-chain at one of the end carbon atoms; the fact that the three conjugated double linkings of the above formulae do not give a considerably higher exaltation than 0.9 seems to be a new proof for the assumption made by Auwers and Eisenlohr (*loc. cit.*) that central disturbances (side-chains) may partly or completely annul the optical anomaly of a conjugated linking. It is more stable than methylmenthatriene (compare Rupe and Liechtenhan, Abstr., 1906, i, 374) and yields a *dihydrobromide*, $C_{11}H_{18}Br_2$. When reduced by sodium in amyl alcohol solution, it yields a mixture of di- and tetrahydro derivatives, whilst in ethyl alcohol, it gives the pure dihydro-compound *tetramethylcycloheptadiene*, $C_{11}H_{16}$, b. p. 64.5–65.5°/12 mm., D^{20}_D 0.8491, n^{20}_D 1.47643. Which pair of conjugated double linkings is thus easily reduced is not known.

The two methyl derivatives of dihydroeucarvone have the following properties: (A) The less readily soluble form gives shining, white monosymmetric leaflets, m. p. 177–178°. That its oxime, $C_{11}H_{17}ON$, decomposes at 265°, and its *semicarbazone*, decomposing at 259°, and also those of compound B, are likewise dimeric is indicated by the high melting points. (B) This modification forms four-sided, prismatic crystals, m. p. 142–143°; its oxime is found to be a mixture of two compounds, m. p.'s 204–205° and 265° respectively, the latter being identical with the oxime of A. Unlike eucarvone, the compounds A and B decolorise permanganate in acetic acid solution only after some minutes; the conclusion is hence drawn that these compounds contain no ethylene linking, and that they are probably stereoisomerides of the structure: $CH_2 \begin{matrix} \diagup CO-CHMe-CH-CH-CHMe-CO \\ \diagdown CMe_2-CHMe-CH-CH-CHMe-CMe_2 \end{matrix} CH_2$

These results render it highly probable that methylmenthatriene contains two conjugated double linkings. T. H. P.

Δ^3 -Butenylbenzene. C. N. RIMMER (*Ber.*, 1911, 44, 2391–2393).—Attempts to prepare Δ^3 -butenylbenzene, $C_6H_5 \cdot CH_2 \cdot CH=CH_2$, have previously given only Δ^2 -butenylbenzene. On condensing allyl bromide and benzyl chloride by means of sodium, it is now shown that in addition to diallyl and dibenzyl, a hydrocarbon, b. p. 64°/10 mm. is formed. This is proved to be Δ^3 -butenylbenzene, since it yields phenylpropionic acid when oxidised by permanganate in acetone.

The hydrocarbon is a mobile, strongly refractive and dispersive liquid, with an odour similar to that of cress leaves; it has D^{20}_D 0.8631, n^{20}_D 1.5059. E. F. A.

Preparation of 2:4:6-Trinitrobenzene from Halogenated Trinitrobenzenes. JACOB MEYER (D.R.P. 234726).—When 1-chloro-2:4:6-trinitrobenzene is vigorously boiled during two hours with finely divided copper in a neutral solvent (such as alcohol), it

barium is eliminated and pure 3 : 4 : 6-trinitrobenzene separates from the cooled solution. The metals capable of reacting in this manner are copper, zinc, magnesium, brass, iron, or aluminium, whilst methyl, ethyl, or amyl alcohols, benzene, acetone, or ether can be employed as solvents.
F. M. G. M.

Barium Oxide as a Reducing Agent. Reduction of Nitrobenzene to Nitroso- and Azo-benzene, Aniline, Phenazine, and Ammonia. TH. ZEREWITINOFF and IWAN VON OSTROMISLENSKY (Ber., 1911, 44, 2402—2409).—When nitrobenzene vapour is passed over a layer of barium oxide heated in a tube at 230°, nitrosobenzene is at first formed, but the reduction goes further, and, in addition to the chief product, azobenzene, considerable quantities of phenazine and aniline and traces of ammonia are formed. Nitrobenzene is exchanged when passed over heated coal or pumice, and also when barium or strontium oxide is substituted for barium oxide.

p-Nitrotoluene under similar conditions gives *p*-toluidine and a crystalline, yellowish-red azotoluene, m. p. 139°. *o*-Nitrotoluene gives exclusively *o*-toluidine. *m*-Dinitrobenzene is not altered by barium oxide.

With barium hydroxide and nitrobenzene only aniline and phenazine are formed.

The formation of nitroso- and azo-benzene is due to the tendency of nitium to form peroxide.

The following new double compounds of phenazine are described: *phenazine-quinol*, $C_8H_4(OH)_2 \cdot 2C_{12}H_8N_2$, forms orange-yellow needles, m. p. 232° (decomp.); *phenazine-resorcinol*, $C_8H_4(OH)_2 \cdot 2C_{12}H_8N_2$, forms bright yellow needles, m. p. 213.5°; *phenazine-catechol* crystallises in stellate aggregates of bright yellow needles m. p. 184°. E. F. A.

Quantitative Investigation of the Sulphonation of Toluene. ARNOLD F. HOLLEMAN and P. CALAND [with T. VAN DER LINDEN and P. WIHAUT] (Ber., 1911, 44, 2504—2522).—The quantities of *o*-, *m*-, and *p*-toluenemonosulphonic acids formed by the action of sulphuric acid on toluene under various conditions have been investigated. The method consisted in sulphonation of the toluene and transformation of the mixture of sulphonic acids into the corresponding sulphonyl chlorides. The composition of the latter mixture was deduced from its first and second melting points.

The influence of temperature, concentration of acid, and amount of toluene was investigated. Increase of temperature favoured the production of para- and meta-acid at the expense of ortho-acid. Concentration of acid, between the limits of 96% and 100%, appeared to be without influence. Increase in the amount of acid favoured the reduction of ortho-acid at low temperatures, but this influence was masked at higher temperatures by the effect due to rise of the latter.

The presence of *m*-toluenesulphonic acid among the products of the sulphonation of toluene has been definitely proved by the isolation of *m*-toluenesulphonamide (m. p. 107°).

The addition of potassium sulphate, mercurous sulphate, and

silver sulphate has been shown to have no influence on the course of sulphonation.

The action of chlorosulphonic acid on toluene has also been studied. *p*-Toluenesulphonic acid is again the main product.

The possible interconversion of the isomeric toluene monosulphonic acids has been investigated. *m*-Toluenesulphonic acid was found unaltered after being heated with sulphuric acid during six hours at 100°. At 35° and at 75°, the transformation of ortho- and para-acids into one another occurs very slowly. At 100° this action has a certain influence on the relative proportion of acids formed during sulphonation. H. W.

Preparation of Chloroalkylarylsulphonyl Chlorides. BADISCHE ANILIN- & SODA-FABRIK (D.R.P. 234913).—When derivatives of *p*-toluenesulphonyl chloride are treated with phosphorus pentachloride and chlorine introduced at a temperature of 120–140°, chlorination takes place in the side-chain, yielding the corresponding chlorinated derivatives.

o-Chlorotoluene-*p*-sulphonyl chloride, $C_7H_6O_2Cl_2S$, colourless needles, m. p. 64–65°, b. p. 183–185°/15 mm., was obtained from *p*-toluenesulphonyl chloride; and *m*-toluenesulphonyl chloride furnished *o*-chlorotoluene-*m*-sulphonyl chloride, colourless crystals, m. p. 42°, b. p. about 190°/31 mm.

o-2-Dichlorotoluene-*p*-sulphonyl chloride, a colourless oil, b. p. 185–190°/15.5 mm., was obtained from *o*-chlorotoluene-*p*-sulphonyl chloride, whilst 6-chlorotoluene-3-sulphonyl chloride furnished 4-dichlorotoluene-3-sulphonyl chloride, colourless crystals, b. p. 182–184°/14 mm. F. M. G. M.

Preparation of a Mixture of 1:4- and 1:5-Dichloronaphthalenes. BADISCHE ANILIN- & SODA-FABRIK (D.R.P. 234913).

—The preparation of dichloronaphthalenes has not in the past been technically satisfactory; it is now found that by working at low temperatures and in the presence of a halogen carrier that a mixture containing over 80% of 1:4- and 1:5-dichloronaphthalenes is obtained, the remainder consisting of the 1:2- and 1:7-isomerides. The naphthalene, accompanied by some freshly sublimed ferric chloride, is treated in carbon tetrachloride solution with chlorine at –10° to 0°. On fractional distillation the greater part distils at 170–190°/40 mm. and when crystallised from alcohol furnishes a colourless, crystalline powder (m. p. 50–60°) consisting of the 1:4- and 1:5-dichloronaphthalenes.

An alternative separation is to treat the crude mixture with sulphuric acid at the ordinary temperature during twenty hours, when the 1:4- and 1:5-derivatives remain unchanged, whereas the isomerides are converted into soluble sulphonic acids. F. M. G. M.

A Constituent of Coal. AMÉ PICTET and LOUIS RANSTEN (Ber., 1911, 44, 2486–2497).—A French gas coal from Montrambert was extracted with boiling benzene and also submitted to distillation under diminished pressure. The extract and distillate were fractionated and shown to contain hexahydrofluorene. On fractionating the extract it was found impossible to obtain fractions of constant

ling point, since the lower boiling fractions readily polymerise. In fractions, analysis showed the ratio C:H to be the same. For investigation, a fraction was used having a b. p. 110—120°/10 mm., 10—250° ordinary pressure, and D_{20}^{20} 0.820. This, when passed through a red-hot tube, yielded fluorene, m. p. 112—113°. When heated with bromine in carbon disulphide solution, dibromofluorene, m. p. 166—167°, was formed, whilst when placed in a desiccator with bromine, it became converted into monobromofluorene, m. p. 101—102°.

On oxidation with potassium permanganate, acetic, adipic, and oxalic acids were formed. Nitration yielded a mixture of products from which, on reduction and benzoylation, a dibenzoyldiaminotetrahydrofluorenol, m. p. 150°, was obtained. From the above experiments the annexed formula is proposed for hexahydrofluorene. When distilled under diminished

pressure at a temperature not exceeding 450°, the same coal yielded a series of more complex fractions in which the ratio C:H was not constant.

H. W.

Triphenylmethyl Peroxide. The Chemistry of Free Radicals. HEINRICH WIELAND (*Ber.*, 1911, 44, 2550—2556).—Elaborating his conception, already applied to $\cdot\text{NPh}_2$ and $\cdot\text{CPh}_3$ (this vol. i. 569), that a free radical R, containing hydrogen, reacts by intermolecular autoreduction and autooxidation in accordance with the scheme $4(\text{R}^{\cdot})\text{H} \rightarrow 2\text{RH} + (\text{R}^{\cdot})_2$, the author suggests that peroxides may dissociate thus: $\text{R}\cdot\text{O}\cdot\text{O}\cdot\text{R} \rightarrow 2\text{R}\cdot\text{O}\cdot$; the resulting radical may or may not react further, as in the preceding scheme; but the spontaneous decomposition of triphenylmethyl peroxide in boiling xylene is assumed to result in the formation of the radical $\text{Ph}_3\text{C}\cdot$. A small portion of this is converted into triphenylcarbinol, at the bulk of it, 60—70%, undergoes rearrangement to phenoxytriphenylmethyl, $\text{OPh}\cdot\text{CPh}_2$, by the polymerisation of which diphenylbenzopinacolone, the chief product of the decomposition of the peroxide, is formed. *Benzpinacolonediphenyl ether*, $\text{OPh}\cdot\text{CPh}_2\cdot\text{CPh}_2\cdot\text{OPh}$, forms colourless plates, and has m. p. about 196°, darkening at 135°, by the usual process, but when heated in carbon dioxide, it becomes yellow at 50° and melts at 215° to a garnet-red liquid. When reduced by zinc in boiling acetic acid, it is converted into phenol and benzhydryl acetate, together with a little substance, m. p. 198°, which probably has the constitution $\text{OPh}\cdot\text{CPh}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHPh}\cdot\text{OPh}$.

When heated at 230—240° in the absence of air, benzpinacolonediphenyl ether undergoes the reverse change to phenoxydiphenylmethyl, which, in accordance with the preceding scheme (except that the phenoxy-group wanders instead of a hydrogen atom), is converted into tetraphenylethylene and *diphenoxydiphenylmethane*, $\text{CPh}_2(\text{OPh})_2$, m. p. 132°; the latter is readily hydrolysed to phenol and benzophenone by boiling acetic and concentrated hydrobromic acids. Since a little phenol and benzophenone are obtained by the depolymerisation of benzpinacolonediphenyl ether by heat, especially in boiling xylene, it is probable that a portion of the phenoxydiphenylmethyl suffers the

normal autoreduction and autoxidation, yielding substances from which the phenol and benzophenone are produced.

Preparation of Phenylbenzyltrimethylammoniumdisulphonate Acid. FARBERGEE FORM. MEISTER, LUCIUS & BACHING (D.R.P. 234915 and 234916).—Sodium phenylbenzyltrimethylammoniumdisulphonate (annexed formula), a

yellow, hygroscopic powder, is prepared by heating sodium benzylmethylammoniumdisulphonate with

methyl sulphate at 50°, and subsequently evaporating under reduced pressure; when heated with aqueous ethylaniline, it furnishes benzylmethylammoniumdisulphonic acid and dimethylammonium-3-sulphonic acid (dimethylmetanilic acid). The second patent states that the methyl sulphate can be replaced by methyl *p*-toluenesulphonate (or other methyl esters), in which case calcium benzylmethylammoniumdisulphonate in the presence of calcium carbonate (or hydroxide) is employed, as the mixture heated at 60°; after separation of the toluenesulphonic acid by known methods, calcium phenylbenzyltrimethylammoniumdisulphonate is obtained as a yellow powder, which is readily soluble in water.

F. M. G. M.

Kinetics of Ammonium Salts. HANS VON HALBAN (*Zeitsch. physikal. Chem.*, 1911, 77, 719—734).—Polemical against Wedekind and Paschke (compare Abstr., 1909, ii, 722; Wedekind and Paschke, Abstr., 1908, i, 723; this vol., i, 628). The contention of these investigators that the rate of decomposition of dissolved quaternary ammonium salts is related to the dissociating power of the solvent is not valid. As already pointed out (*loc. cit.*), the reactions are relatively slow in solvents containing hydroxyl groups. The influence of the corresponding nitrate on the rate of decomposition of *d*-phenylbenzylmethylpropylammonium iodide is much smaller than Wedekind and Paschke state, and an alternative explanation of this effect is given. The very small temperature-coefficient (1.02 for a rise of temperature of 10°) given by these authors for the rate of formation of a quaternary ammonium salt is due to experimental error; the true value is 1.7.

Phenylbenzyltriethylammonium iodide forms a crystalline compound with chloroform, and *p*-bromophenylbenzyltrimethylammonium iodide a similar compound with bromoform, which contains a molecule of the solvent. In contrast to solutions in chloroform, quaternary ammonium salts are only slightly polymerised in tetrachloroethane. G. S.

The Metallic Salts of Trinitrophenols and Trinitroresols. HERMANN KAST (*Zeitsch. ges. Schiess-sprengstoffwesen*, 1911, 8, 7—9, 31—34, 67—70. Compare *Annalen*, 1843, 48, 336; *Zeitsch. Chem.* 1865, 189).—A description of the preparation of the following compounds in crystalline form, with special details as to their explosive qualities.

Salts of picric acid.—Potassium, ammonium, and sodium: reddish yellow needles, the latter containing one molecule of water of crystallisation.

Calcium, $(C_6H_2O_7N_3)_2Ca, 3H_2O$ (also 5 or $10H_2O$); barium, $(C_6H_2O_7N_3)_2Ba, 3$ or $5H_2O$; magnesium, $(C_6H_2O_7N_3)_2Mg, 3H_2O$ (also or $5H_2O$), two mols. of which persist until 130° , and zinc, $(C_6H_2O_7N_3)_2Zn, 8H_2O$ (also 2, 6 or $9H_2O$), two mols. of which persist until 130° , all form reddish-yellow needles. Ferrous, $(C_6H_2O_7N_3)_2Fe, 7$ or $8H_2O$.

amorphous, green leaflets. Ferric, $(C_6H_2O_7N_3)_2Fe, 11H_2O$, reddish-yellow crystals. Cuprous, $(C_6H_2O_7N_3)_2Cu, 5H_2O$ (also 4 or $11H_2O$), two mols. of which persist until 130° ; forms small, greenish-yellow needles. Silver, reddish-yellow, glistening needles unstable in light. Aluminium, $(C_6H_2O_7N_3)_2Al(OH), 7H_2O$, small, reddish-yellow needles. Lead, $(C_6H_2O_7N_3)_2Pb, 1$ or $4H_2O$, a yellow, crystalline powder.

Salts of trinitroresorcinol.—Potassium, $C_7H_2O_7N_3K$. Sodium, $C_7H_2O_7N_3Na, 2H_2O$, small, yellow needles. Ammonium and calcium, $(C_7H_2O_7N_3)_2Ca, 4H_2O$, reddish-yellow needles. Barium, $(C_7H_2O_7N_3)_2Ba, H_2O$, small, sulphur-yellow leaflets. Magnesium and zinc, reddish-yellow powders, with H_2O , three of which in the zinc salt persist until 130° . Cuprous, $(C_7H_2O_7N_3)_2Cu, 21H_2O$, small, greenish-yellow needles, is stable until 130° . Silver, reddish-yellow needles (compare Abstr., 1885, 531). Aluminium, $(C_7H_2O_7N_3)_2Al(OH), 5H_2O$, reddish-yellow needles, darkening in sunlight. Lead, $(C_7H_2O_7N_3)_2Pb, H_2O$, sulphur-yellow leaflets. Ironous, $(C_7H_2O_7N_3)_2Fe, 2H_2O$, glistening, greenish-yellow needles, and ferric, brown crystals, decomposed by boiling water. F. M. G. M.

Preparation of 4-Chloro-6-nitro-2-aminophenol. AKTIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION (D.R.-P. 234742).—When chloro-2-acetylaminophenol is treated with dilute nitric acid, 4-chloro-6-nitro-2-acetylaminophenol, m. p. $150-160^\circ$, is produced, which when hydrolysed by alkali hydroxides yields 4-chloro-6-nitro-2-aminophenol a yellowish-brown powder. F. M. G. M.

Derivatives of 1:2-Dimethylbenzene [o-Xylene]. II. EMIL REICHERT (*Ber.*, 1911, 44, 2498—2503. Compare Abstr., 1909, i, 61).—The phenylhydrazone of the o-4:5-xyloquinone described previously, when treated with sodium hyposulphite in alcoholic solution, yields 5-amino-o-4-xenol; the acetyl derivative crystallises in thin plates, which sinter at 184° , m. p. $190.5-191^\circ$, and when heated res. 3-ringideneamino-o-4-xenol, white needles, m. p. $93-94^\circ$. 5-Acetyl-amino-o-4-xenyl acetate forms fine, white, silky needles, m. p. $156-157^\circ$, and 5-diacetyl-amino-o-4-xenyl acetate crystallises in hexagonal plates, m. p. $100.5-101.5^\circ$.

o-Aminophenol when treated with acetic anhydride and sodium acetate yields o-diacetylaminophenyl acetate in long, colourless needles, m. p. $78-79^\circ$.

4:5-Dihydroxy-m-xylene, obtained by the reduction of o-4:5-xyloquinone with aqueous sulphurous acid or sodium hyposulphite, forms colourless, slender prisms sintering at 85° , m. p. $87-88^\circ$.

Attempts to prepare a colourless modification of o-4:5-xyloquinone were fruitless. H. W.

Chloroguaiacols. TEMISTOCLE JONA and G. B. PORZI (*Gazzetta* 1911, 41, i, 722—737).—**5-Aminoguaiacol hydrochloride**, $C_7H_7O_2Cl$, from 5-nitro-1-acetylguaiacol (compare Cousin, *Abstr.*, 1899, i, 588) forms pale greenish-white crystals. **5-Aminoguaiacol**, $C_7H_7O_2$, was obtained in grey crystals, m. p. 125—127°, which were not quite pure; it gives a reddish-brown coloration with ferric chloride. **5-Benzoylaminoguaiacol benzoate**, $C_{21}H_{17}O_4N$, forms colourless crystals, m. p. 162—164°, and does not give a coloration with ferric chloride. **5-Acetylaminoguaiacol**, $C_9H_{11}O_3N$, forms colourless crystals, m. p. 116—119°, and gives the phenol reaction with ferric chloride. **5-Chloroguaiacol**, $C_7H_5O_2Cl$, obtained by the Sandmeyer reaction from aminoguaiacol, has b. p. 237—239°/760 mm. (corr.), m. p. 161—163°. It gives a yellow coloration with ferric chloride. **5-Chloroguaiacol benzoate**, $C_{14}H_{11}O_3Cl$, crystallises in long, colourless needles, m. p. 56—58°. **5-Chloroguaiacol acetate**, $C_9H_7O_2Cl$, crystallises in colourless leaflets, m. p. 42—44°. **5-Chloroguaiacol ethyl ether**, $C_9H_9O_2Cl$ (prepared with ethyl iodide), forms colourless crystals, m. p. 49—51°.

4-Aminoguaiacol acetate is obtained by reducing with phenylhydrazine the acetyl derivative of benzeneazoguaiacol.

4-Acetylaminoguaiacol, $C_9H_{11}O_3N$ (from 4-aminoguaiacol), forms colourless crystals, m. p. 111—113°, and gives the phenol reaction with ferric chloride. **4-Chloroguaiacol**, $C_7H_5O_2Cl$ (prepared by the Sandmeyer reaction from 4-aminoguaiacol acetate), is a colourless, crystalline substance, m. p. 158—161°, b. p. 241—243°/760 mm. (corr.). Its *benzoyl* derivative, $C_{14}H_{11}O_3Cl$, crystallises in colourless scales having a mother-of-pearl lustre, m. p. 79—80°.

The benzoyl derivative of chloroguaiacol obtained by Peratoner and Ortoleva (*Abstr.*, 1898, i, 641) had m. p. 76—77°, and was probably identical with the derivative just described. R. V. S.

Preparation of 1:4-Dihydroxynaphthalene Monoalkyl Ethers. FARBERWERKE VORM. MEISTER, LUCIUS & BÄRNING (D.R.P. 234411).—A satisfactory yield of 1:4-dihydroxynaphthalene monoalkyl ethers can be obtained by heating 4-amino-1-naphthol hydrochloride with alcohol during twelve hours at 170—180°. When methyl alcohol is employed under these conditions, 200 parts of the aminonaphthol yield 120—130 parts of the *monomethyl ether*, reddish-white crystals, m. p. 131°. F. M. G. M.

Some Derivatives of Hydroxyquinol. IV. GUIDO BARGILLI and ERMANNO MARTEGIANI (*Atti R. Accad. Lincei*, 1911, [v], 20, i, 18—25. Compare this vol., i, 68, 305).—In the course of attempts to demonstrate the structure of 2:4:5-trimethoxypropiofenone and of its dimethyl ether, previously described, the authors have prepared some new derivatives of these substances. Trimethoxypropiofenone is not acted on by bromine and sodium hydroxide (compare Storer and Wehln, *Abstr.*, 1903, i, 40).

Hydroxyquinol trimethyl ether may be prepared with good yield by the action of methyl sulphate on triacetylhydroxyquinol, a concentrated solution of sodium hydroxide being added in small portions. Hexamethoxydiphenyl is not formed when the reaction is carried out in this way.

The 2-hydroxy-4:5-dimethoxypropiophenone previously mentioned crystallises in small, colourless needles, m. p. 124—126° (softening at 99°). The *acetyl* derivative, $C_{13}H_{16}O_5$, also crystallises in needles, m. p. 117—118°. The *benzoyl* derivative, $C_{15}H_{18}O_5$, forms long needles, m. p. 110—111°.

2:4:5-Trimethoxypropiophenonephenylhydrazone has m. p. 113°. 2:4:5-Trimethoxypropiophenonemonoxime (prepared with amyl nitrite), $C_{13}H_{16}O_4N$, crystallises in scales having a slight yellowish-green colour, and has m. p. 146—148°. It gives a deep reddish-brown coloration with an alcoholic solution of nickel acetate. When it is treated with hydroxylamine hydrochloride the dioxime, $C_{13}H_{16}O_4N_2$, is formed, which crystallises in prismatic needles, m. p. 206—207°. An alcoholic solution of the substance yields with an alcoholic solution of nickel acetate a bright red precipitate; with ammonium palladichloride it gives a pale yellow substance; with ferrous sulphate in the presence of pyridine an intense red coloration and a red precipitate are produced. The substance seems, therefore, to be a *syndioxime* (compare Schucheff, Abstr., 1908, i, 554). When the above monoxime is treated with phenylhydrazine, the *oxime-phenylhydrazone*, $C_{15}H_{20}O_4N_2$, is obtained as a white, crystalline powder, m. p. 246—248°. By boiling the monoxime, dioxime, or oxime-phenylhydrazone with dilute acids, small quantities of a crystalline substance, m. p. 133°, are obtained.

R. V. S.

Some Derivatives of Hydroxyquinol. V. GUIDO BARGELLINI and S. ACCIARI (*Atti R. Accad. Lincei*, 1911, [v], 20, ii, 118—124. Compare this vol., i, 305).—Hydroxy-ketones related to hydroxyquinol have been prepared by the action of persulphates on less highly oxygenated phenols in alkaline solution (compare Kumagai and Wolfenstein, Abstr., 1908, i, 159). It is further found that the saponification of 2:4:5-trimethoxyacetophenone by means of hydrobromic acid (compare Stoermer, Abstr., 1908, i, 190) yields 1:4-dihydroxy-5-methoxyacetophenone.

The action of potassium persulphate or of ammonium persulphate on 2-hydroxy-4-methoxyacetophenone (paeonol) in alkaline solution under diverse conditions yields 2:5-dihydroxy-4-methoxyacetophenone, $C_{11}H_{10}O_5$, which crystallises in white scales having a yellow tinge, m. p. 164°. When dissolved in concentrated sulphuric acid, it gives a yellowish-green coloration. Its aqueous solution gives with ferric chloride a red coloration. The *acetyl* derivative, $C_{13}H_{14}O_6$, forms small, colourless needles, m. p. 118—119°. The *benzoyl* derivative is a yellowish-white, crystalline powder, m. p. 215°. When sodium peroxide is used instead of a persulphate in the above oxidation, the monol remains unchanged, whilst when hydrogen peroxide is employed a mixture of products is obtained. Esterification of 2:5-dihydroxy-4-methoxyacetophenone with methyl sulphate yields both the trimethoxy- and dimethoxy-derivatives. The former can be extracted with ether from the alkaline solution, and is identical with the 2:4:5-trimethoxyacetophenone, m. p. 101—102°, previously described (Bargellini and Avrutin, this vol., i, 68). From the alkaline liquid after acidification, 2-hydroxy-4:5-dimethoxyacetophenone, $C_{10}H_{12}O_4$,

can be extracted with ether; it crystallises in yellowish-white needles, m. p. 114—115°. Its aqueous solution gives a green coloration with ferric chloride. The *acetyl* derivative, $C_{13}H_{14}O_5$, forms small, colorless needles, m. p. 146—147°. With anisaldehyde, 2-hydroxy-4,4-dimethoxyacetophenone yields 2'-hydroxy 4:4':5'-trimethoxychalcone, which crystallises in small, red needles, m. p. 130°. It dissolves in concentrated sulphuric acid, giving an intense orange-yellow coloration.

When trimethoxyacetophenone in acetic acid solution is boiled for two hours with hydrobromic acid (D 1.47), 2:4-dihydroxy-5-methoxyacetophenone, $C_9H_{10}O_4$, is produced; it forms yellowish-white needles, m. p. 166°. Its aqueous solution gives a red coloration with ferric chloride. The *acetyl* derivative, $C_{11}H_{14}O_6$, crystallises in long, colourless needles, m. p. 127—128°.

R. V. S.

A Nitroso-compound of Dimethoxyphenol, and its Derivatives. RUDOLF FABINY and TIBOR SZÉKI (*Ber.*, 1911, 44, 2293—2298).—The substance obtained by boiling asaronic acid in aqueous solution with sodium nitrite, and formerly supposed to be 4:5-dimethoxy-o-benzoquinoneoxime or its tautomeride (*Abstr.*, 1907, i, 45), is now shown to be 2:5-dimethoxy-1:4-benzoquinoneoxime or the tautomeric 4-nitroso-2:5-dimethoxyphenol, and a number of its derivatives are described. The substance on repeated crystallisation from hot acetic acid forms transparent, lustrous citreous yellow needles identical in composition with the red form described previously.

On methylation with methyl sulphate, it gives 4-nitroso-1:2:5-trimethoxybenzene, m. p. 191°, which crystallises in long, reddish-yellow needles from alcohol. The reduction to 4-amino-2:5-dimethoxyphenol, m. p. 157° (*loc. cit.*), is best effected by ammonia and hydrogen sulphide; the *acetylamino*-compound, m. p. 180°, crystallises from boiling water, and the *diacetyl* derivative, m. p. 190°, from either water or boiling alcohol; the *dipropionyl* derivative, m. p. 131°, also crystallises from alcohol. On oxidation with 50% nitric acid the aminodimethoxyphenol yields 2:5-dimethoxy-1:4-benzoquinone (compare Schüler, *Abstr.*, 1907, i, 700), and on treatment with ethyl chlorocarbonate in alcohol gives *ethyl 4-hydroxy-2:5-dimethoxyphenyl-aminoformate*, m. p. 143°, which crystallises from benzene in glancing leaflets, and is readily soluble in alcohol, chloroform, or acetic acid. The *acetyl* derivative of this, m. p. 135°, crystallises from hot alcohol, and the *carboxymethyl ether*, $CO_2H \cdot CH_2 \cdot O \cdot C_6H_3(OMe)_2 \cdot NH \cdot CO_2Et$, m. p. 108°, obtained by condensation with ethyl bromoacetate in presence of sodium and alcohol, crystallises from alcohol.

4-Acetylamino-2:5-dimethoxyphenoxycetic acid,

m. p. 172°, obtained by condensing ethyl bromoacetate with 4-hydroxy 2:5-dimethoxyacetanilide, forms colourless crystals from alcohol.

Several of the substances described exert an antipyretic action, which is, however, less marked than that due to phenacetin.

T. A. H.

Aromatic Tellurinium Compounds with the same Hydrocarbon Residue. CHARLES LEONARD (*Ber.*, 1911, 44, 2287—2293). Tellurium tetrachloride reacts with the Grignard reagent to form telluronium compounds containing three aromatic hydrocarbon residues. These react in part with the Grignard reagent present to form the corresponding diaryl tellurides and diaryl hydrocarbons, as: $R_3TeCl + R \cdot MgBr = R_2Te + R_2 + MgClBr$. In addition, the diaryl telluride so formed reacts with hydrochloric acid subsequently added, in presence of air, to form some diaryltellurinium dichloride, which in turn is decomposed on addition of water, forming a basic chloride, thus:

In these equations R represents an aromatic hydrocarbon residue. In certain cases irregularities were observed. With magnesium *p*-tolyl iodide, no di-*o*-tolyl was formed, but, instead, an unidentified high-boiling hydrocarbon. With magnesium *p*-tolyl bromide, the *p*-tolyl obtained was not identical with that of Weiler (*Abstr.*, 1899, i, 490). A description is given of the method used for the separation of all the substances formed.

Triphenyltellurinium iodide, $TePh_3I$, sinters at 245°, has m. p. 47—249°, and crystallises from hot water in small needles. The corresponding bromide, m. p. 259—260°, separates from hot water in small prisms. The chloride, m. p. 244—245°, crystallises from dry alcohol on addition of ether in long, slender needles.

Tri-*p*-tolyltellurinium iodide, m. p. 232—233° (decomp.), crystallises from alcohol in six-sided tablets. The bromide, m. p. 265—266° (decomp.), crystallises from water or from alcohol on addition of ether. The chloride, m. p. 260—261°, crystallises in small prisms from dry alcohol on addition of ether.

Tri-*o*-tolyltellurinium iodide, m. p. 195—196°, forms small, four-sided columns from water or alcohol on addition of ether. Its aqueous solution is precipitated by picric acid. T. A. H.

Preparation of ω -*p*-Alkylhydroxyphenylethylamines and their *N*-Alkyl Derivatives. AKTIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION (D.R.P. 234795).—It is found that ω -*p*-alkylhydroxyphenylethylamines can be readily prepared by treating primary alkylhydroxyphenylethyl alcohols with phosphorus pentahalides and subsequently heating the ω -*p*-alkylhydroxyphenylethyl halide so obtained with ammonium hydroxide (or the required alkylamino) in a closed vessel at 100°.

***p*-Methoxyphenylethyl alcohol**, m. p. 22°, b. p. 143°/13 mm. (prepared from ethylene chloride and magnesium *p*-anisyl bromide), furnished under these conditions a 50—60% yield of ω -*p*-methoxyphenylethylamine, and when dimethylamine was employed, an 80% yield of ω -*p*-methoxyphenylethyldimethylamine; the intermediate chloride has m. p. 100—105°/7 mm.

***p*-Ethoxyphenylethyl alcohol**, prepared from ethylene chlorohydrin and magnesium *p*-phenetyl bromide, can also be employed in the foregoing reaction; it has m. p. 40° and b. p. 135—140°/7 mm.; the intermediate chloride has b. p. 125—130°/7 mm. F. M. G. M.

Phytosterols of Soy Bean. HERMANN MATTHEI and A. DUMKE (*Arch. Pharm.*, 1911, 249, 436—444. Compare this vol., i, 831; Kishi and Block, *Abstr.*, 1907, i, 521; Keimatsu, this vol., i, 766).—Soy bean oil contains 0.7% of unsaponifiable matter, of which 55% is solid and crystalline, and is composed of stigmasterol 2.4%, and a new phytosterol 97%, and 45% is liquid.

The crude unsaponifiable matter was mixed with light petroleum and the mixture strongly cooled, when it separated into (1) a solid, crystalline product; (2) a solution in light petroleum of a viscous, brown material. The solid product was acetylated and the acetylated product brominated in ether solution, when stigmasterol acetate dibromide, m. p. 205—206° (compare Windaus and Hauth, *Abstr.*, 1907, i, 129), separated. The portion of the brominated product soluble in ether was recovered in crystalline form by gradual addition of water to its solutions in alcohol. It proved to be *phytosterol acetate dibromide*, $C_{27}H_{46}(or\ 48)O_2Br_2$, m. p. 125°, and on reduction and subsequent hydrolysis gave the corresponding *phytosterol*, $C_{27}H_{46}(or\ 48)H_2$, m. p. 139°, $[\alpha]_D^{25} - 22.83^\circ$.

The liquid product had iodine number 124.4, $n_D^{20} - 1.455$, $[\alpha]_D^{20}$ 0°, and gave the colour reactions of the phytosterols. On treatment with digitonin (compare Windaus, *Abstr.*, 1909, i, 172) a small amount of the material separated as a crystalline additive product, $[\alpha]_D^{25} - 44.66^\circ$ in methyl alcohol, but no separation of the liquid into two components was thereby effected. The liquid has the same empirical composition as the phytosterol referred to above. T. A. II

Action of Chlorine on "Saccharin." PASQUALE DIETONE (*Gazzetta*, 1911, 41, i, 698—705).—When "saccharin" is subjected to the prolonged action of nascent chlorine (from hydrochloric acid and potassium chlorate), *o*-chlorobenzoic acid is obtained. When the duration of the action is more limited, however, a substance is obtained to which the constitution of *potassium o-iminosulphobenzoic acid*, $NH \cdot SO(OK) \cdot C_6H_4 \cdot CO_2H$, is ascribed. In this case "saccharin" is boiled with dilute hydrochloric acid, and potassium chlorate is added from time to time until the "saccharin" is completely dissolved, and the boiling is then continued for a few minutes to expel excess of chlorine. The above-mentioned substance, $C_7H_5O_5NSK$, crystallises from the solution, after concentration, in the form of transparent, colourless, tabular, rhombic crystals [S. Di Franco: $n_D^{20} = 1.46335$; $d_4^{20} = 1.79093$], m. p. 285—286°. The barium salt,

crystallises with $1\frac{1}{2}H_2O$, which it loses at 110° . From it the free acid may be obtained. When the potassium salt is boiled with 5% potassium hydroxide, ammonia is evolved, and *potassium o-sulphobenzoate* is obtained. *Barium sulphobenzoate*, $C_7H_4O_5SBa \cdot 2H_2O$, was also prepared. R. V. S.

Preparation of Esters of Cinnamic Acid. FARBENFABRIK VORM. FRIEDR. BAYER & Co. (D.R.-P. 235357).—*Ethylene cinnamate*, a colourless, odourless oil, b. p. 190—195°/11 mm., is prepared by

being together equal quantities of ethylene glycol and cinnamic acid during thirty hours at 140° in the presence of concentrated sulphuric acid. *Glycol monocinnamate*, a yellow, oily liquid, and *ethylene chlorohydrin ethoxycinnamate*, a yellow liquid, and other substances allied to the constituents of Peru balsam are discussed in the original.

F. M. G. M.

Refraction of Light by *allo*- and *iso*-Cinnamic Acids. HANS FORBE and FAITZ REUSS (*Ber.*, 1911, 44, 2735—2739).—Two specimens of *allocinnamic acid* were examined: (1) m. p. 68° , prepared by the action of hydrogen on phenylpropionic acid in presence of colloidal palladium, and (2) m. p. 67 — 68° , prepared from an aniline salt.

With acid (1) the following refractometric measurements were made on the melted acids: (a) of *allocinnamic acid* from 71.7° to 74.4° , (b) of *isocinnamic acid*, m. p. 58° , from 70.7° to 55.8° , and (c) of *isocinnamic acid*, m. p. 42° , from 45.8° to 51.1° . The results, plotted against the temperature, all fell on a straight line, so that the refraction of all three acids is continuous and diminishes proportionally with the temperature, as happens with compounds known to be chemical individuals. The results obtained with *allocinnamic acid* (2) from 77.3° to 22.6° also fell on a straight line with the same slope as, and only very slightly distant from, that of the (1) acids. Fused *allo*- and *iso*-cinnamic acids are hence to be regarded as optically identical.

T. H. P.

Transformations of *allo*- and *iso*-Cinnamic Acids in the Fused and Crystalline States. HANS STOBBE (*Ber.*, 1911, 44, 2739—2754. Compare preceding abstract).—The author has confirmed and extended the observations of Liebermann (*Abstr.*, 1903, 255; 1909, i, 303; 1910, i, 36, 175), Billmann (*Abstr.*, 1909, 155, 383; 1910, i, 346), Erleumeyer (*Abstr.*, 1891, 200; 1896, 46), Erleumeyer, jun. (*Abstr.*, 1906, i, 429; 1907, i, 318; 1909, 156, 647, 648), Paal and Hartmann (*Abstr.*, 1909, i, 926), and Koerner (*Abstr.*, 1910, i, 114) on *allo*- and the two *iso*-cinnamic acids. In the experiments described, extreme care was taken to avoid accidental seeding of the fused or crystalline masses under examination.

By crystal-seeding, the crystalline acid m. p. 42° can be converted into that with m. p. 68° (with development of considerable heat) or 67 , and the latter into that with m. p. 68° .

When the crystalline 42° -acid is heated in a sealed tube for eighty hours at 37° , or the 58° -acid for thirty hours at 52° , no change occurs; but the 42° -acid is transformed completely into the 68° -acid in five minutes at -80° and almost instantaneously at -180° ; with the 58° -acid similar conversion takes place in three hours at -80° and in ten minutes at -180° . The 68° -acid undergoes no change at either -80° or -180° , so that, in all cases, the most labile acid (42°) is converted, by grinding (*Liebermann, loc. cit.*) or cooling, into the stable *allo*-acid more rapidly than is the less labile form (58°). The two labile acids appear to be only metastable forms of a single chemical compound, trimorphous *cis*-cinnamic acid.

ABSTRACTS OF CHEMICAL PAPERS.

If a few milligrams of the fused 68°-acid, heated for 0.5-5 minutes to 72-80°, are cooled to the ordinary temperature or to -14°, the result was almost always the 42°-acid, but occasionally the 58°-acid; but 0.05-1.0 gram of the 68°-acid, on heating to 80-103° for ten minutes or for several hours, and then cooling to the ordinary temperature or to -14°, solidifies to the 68°-acid more frequently than to the 42°-acid.

The observation of Liebermann and of Billmann, that the fused 42° and 58°-acids always solidify to the 42°-acid on cooling to the ordinary temperature or to 0°, is confirmed, but if the cooling is effected in a mixture of ice and salt, sometimes the 42°-acid and sometimes the 58°-acid separates; separation of the former can always be recognised by the slowness with which crystallisation occurs. Further, if the fusion from the 42° or 58°-acid is immersed in a mixture of ether and carbon dioxide or in liquid air, it forms an amorphous, glassy mass with a concave, funnel-shaped surface, and shows no tendency to crystallise, even after some hours; but if the mass is removed from the cooling mixture so that its temperature rises, the concavity of the surface gradually disappears, and it undergoes a usually sudden and always rapid crystallisation, the 58°-acid invariably separating, so that these two labile acids, which in the fused condition are optically identical, can be mutually interconverted without any seeding being necessary.

Results similar to the above were obtained on cooling the fused 68°-acid in ice and salt, ether and carbon dioxide, or liquid air, the only divergence being that occasionally, in addition to the 42° or 58°-acid, the 68°-acid also separated.

Optical identity (compare preceding abstract) of these three acids does not, therefore, always present itself, and the conclusion is drawn that there are in reality two chemically different isomeric acids: (1) monomorphous *allocinnamic* acid, m. p. 68°, and (2) dimorphous *isocinnamic* acid, m. p. 42° and 58°. T. H. P.

Oxidation of *allo*-Cinnamylideneacetic Acid. C. N. RING (Ber., 1911, 44, 2389-2391).—Doebner (Abstr., 1890, 1274) has shown that cinnamylideneacetic acid, when cautiously oxidised with potassium permanganate, is converted into benzoic acid and racemic acid. It is now shown that *allo*-cinnamylideneacetic acid,

under similar conditions is converted into benzoic acid and meso-tartaric acid. The two cinnamylideneacetic acids are accordingly related in the same manner as fumaric and maleic acids, the isomerism being due to the double linking 1:2. The double linking is hardly concerned, since both isomerides when distilled with quinoline give the same stable phenylbutadiene. E. F. A.

Reaction between Organomagnesium Compounds and Cinnamylidene Esters. III. Reactions with the isomeric Methyl Esters of Cinnamylideneacetic Acid. GRACE F. RAYNOLDS (Amer. Chem. J., 1911, 46, 198-211. Compare Abstr. 1907, i, 852; 1908, i, 988).—The action of magnesium alkyl or aryl

as the isomeric methyl cinnamylidenacetates may give rise to three different classes of compounds: (i) tertiary alcohols,

formed by replacement of the methoxy-group and addition of the magnesium compound to the carbonyl group; (ii) unsaturated ketones, $\text{CHPh}\cdot\text{CH}\cdot\text{CHR}\cdot\text{CH}_2\cdot\text{COR}$, produced by 1:4-addition and simultaneous replacement of the methoxy-group; (iii) unsaturated esters of the type $\text{CHPh}\cdot\text{CH}\cdot\text{CHR}\cdot\text{CH}_2\cdot\text{CO}_2\text{Me}$, formed by 1:4-addition only. It is noted that the nature of the product depends on the magnesium compound employed. Whilst magnesium phenyl bromide forms only an unsaturated ketone and magnesium ethyl bromide a tertiary alcohol, the action of magnesium benzyl bromide yields a mixture of compounds belonging to all three classes.

Methyl allorcinnamylidenacetate, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{Me}$, obtained by the action of methyl alcohol and hydrogen chloride on the corresponding acid, is a liquid, which solidifies at -15° to a white, crystalline mass, and is partly converted into the isomeric ester by distillation under diminished pressure. Both esters react with magnesium phenyl bromide, yielding β -phenyl- β -styrylpropionophenone (Kohler, Abstr., 1915, i, 258), which is converted by the further action of magnesium benzyl bromide into *ayce-tetraphenyl- Δ^2 -penten- ϵ -ol*,

The latter compound forms slender, white needles, m. p. 134° , and is oxidised by potassium permanganate to benzoic acid and *ay-triphenyl-*

butyrolactone, $\begin{matrix} \text{CHPh}\cdot\text{CO} \\ \text{CH}_2\cdot\text{CPh}_2 \end{matrix} > \text{O}$, which crystallises in long, iridescent needles, m. p. 157° . Experiments carried out with the isomeric ethyl cinnamylidenacetates under similar conditions showed that *o*-allyl-ester reacts with magnesium phenyl bromide more readily than the isomeric *p*-ester.

The interaction of magnesium benzyl bromide and methyl cinnamylidenacetate yields (1) *o*- α -diphenyl- γ -benzyl- Δ^2 -hexen- ϵ -one,

which is a viscid, lemon-yellow liquid, b. p. $265^\circ/15$ mm., and yields a dibromide, $\text{C}_{20}\text{H}_{22}\text{OBr}_2$, m. p. 165.5° ; (2) *o*- α -diphenyl- ϵ -benzyl- Δ^2 - γ -endien- ϵ -ol, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{C}(\text{CH}_2\text{Ph})_2\cdot\text{OH}$, a mobile, lemon-yellow liquid, b. p. $200^\circ/10$ mm.; the tetrabromide forms slender needles, m. p. 227° (decomp.); (3) β -benzyl- γ -benzylidenebutyric acid,

which crystallises in heavy, iridescent plates, m. p. 144° , yields a crystalline methyl ester, m. p. 66° , and is oxidised by potassium permanganate in aqueous sodium carbonate solution to benzoic and benzylsuccinic acids.

a-Phenyl- ϵ -ethyl- Δ^2 - γ -heptadien- ϵ -ol, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CET}_2\cdot\text{OH}$, obtained by the action of magnesium ethyl bromide on methyl cinnamylidenacetate, is a pale yellow, mobile liquid, b. p. $169^\circ/0$ mm. It is accompanied by a viscid liquid, b. p. $278-285^\circ/10$ mm., which deposits an ester, crystallising in needles, m. p. 136° , when kept. Hydrolysis of the latter substance with alcoholic potassium hydroxide yields an acid, m. p. 230° . The constitution of the last-mentioned substances has not been determined.

F. B.

Reaction between Unsaturated Compounds and Organo-zinc Compounds. II. **ELMER P. KOHLER, GERTRUDE L. HARRINGTON, and A. L. MACLEOD** (*Amer. Chem. J.*, 1911, 43, 217-236).—It has been shown previously (Abstr., 1910, i, 484) that the zinc compounds of esters of bromoacetic acid react with $\alpha\beta$ -unsaturated lactones, yielding unsaturated hydroxy-acids, and from this the conclusion was drawn that the addition of organo-zinc compounds occurs only in the 1:2-position. The present paper deals with the interaction of phenyl styryl ketone and the zinc derivatives of the methyl or ethyl esters of α -bromopropionic, α -bromobutyric, α -bromoisobutyric, and bromomalononic acids. It is found that both 1:2- and 1:4-addition may take place with the formation of the compounds:

- (I) $\text{CHPh}:\text{CH}:\text{CPh}(\text{O}\cdot\text{ZnBr})\cdot\text{CHR}\cdot\text{CO}_2\text{R}'$ and
(II) $\text{ZnBr}\cdot\text{O}\cdot\text{CPh}:\text{CH}:\text{CHPh}\cdot\text{CHR}\cdot\text{CO}_2\text{R}'$,

the relative proportions of the two products depending on the nature of the bromo-ester, $\text{CHRBr}\cdot\text{CO}_2\text{R}'$, employed.

When decomposed with acids, the zinc compounds of the first type yield esters of unsaturated hydroxy-acids,

whilst those belonging to the second type give rise to esters of lactonic acids of the formula: $\text{COPh}\cdot\text{CH}_2\cdot\text{CHPh}\cdot\text{CHR}\cdot\text{CO}_2\text{R}'$. The zinc compounds produced by 1:4-addition may also yield unsaturated lactones, according to the scheme:

The relative amounts of the products formed by 1:2- and 1:4-addition were determined by heating the mixtures with aqueous sodium carbonate, whereby the lactones and ketonic esters are converted into the sodium salts of the corresponding ketonic acids, whilst the unsaturated hydroxy-esters remain practically unchanged. The results thus obtained were as follows, the value first given being the percentage of the product formed by 1:2-addition: methyl α -bromoacetate, 100%, 0%; methyl α -bromopropionate, 55%, 45%; methyl α -bromobutyrate, 50%, 50%; methyl α -bromoisobutyrate and methyl bromomalonate, 0%, 100%.

In several cases no reaction occurred when the bromo-esters were heated with zinc and the unsaturated ketone in benzene solution. The reaction is, however, readily induced by the addition of a small quantity of the copper salt of ethyl acetoacetate, or of other copper compounds which are soluble in benzene.

The action of zinc on methyl bromoacetate and phenyl styryl ketone has been re-investigated, and the product, after removal of methyl β -hydroxy- β -phenyl- α -benzylidenobutyrate, carefully examined for methyl benzoylphenylbutyrate, which would be formed by a 1:4-addition, but no evidence of its presence could be obtained. Methyl β -hydroxy- β -phenyl- γ -benzylidenobutyrate decomposes below 150° into methyl acetate and phenyl styryl ketone; a similar decomposition into potassium acetate and phenyl styryl ketone takes place on treating the ester with alcoholic potassium hydroxide. When hydrolysed with aqueous sodium carbonate, it yields the corresponding acid, $\text{CHPh}:\text{CH}:\text{CPh}(\text{OH})\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, which crystallises in colourless needles.

147° (decomp.). When warmed with a small quantity of hydrochloric acid the hydroxy-ester is converted into a viscid oil, which is hydrolysed by alcoholic potassium hydroxide to β -phenylcinnamylidenecacetic acid, $\text{Ph}\cdot\text{CH}\cdot\text{CPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$; this forms pale yellow, slender needles, m. p. 145—146°.

The product obtained by the interaction of zinc, ethyl α -bromopropionate and phenyl styryl ketone in benzene solution, when decomposed with hydrochloric acid and heated with aqueous sodium carbonate, yields a mixture of two stereoisomeric ethyl β -hydroxy- β -phenyl- γ -benzylidene- α -methylbutyrate,

which may be separated by repeated crystallisation from methyl alcohol. The less soluble isomeride crystallises in slender needles, m. p. 107°, instantly decolorises bromine at the ordinary temperature, and decomposes above its m. p. into ethyl propionate and phenyl styryl ketone. When warmed with alcoholic potassium hydroxide, it yields phenyl styryl ketone and potassium propionate. The stereoisomeride, which is produced only in small quantity, separates from alcohol in transparent prisms, m. p. 81°, and resembles the preceding compound in its chemical properties.

The alkaline solution from which the above esters were separated yields on acidification two stereoisomeric γ -benzoyl- β -phenyl- α -methylbutyric acids, $\text{CH}_2\text{Bz}\cdot\text{CHPh}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$, which are separated by crystallisation from ether and light petroleum. Of these isomerides, one obtained in larger quantity crystallises in slender, feathery plates, m. p. 149°, and yields a methyl ester crystallising in needles, m. p. 41°. The ethyl ester has m. p. 41°. The stereoisomeric acid forms slender needles, m. p. 105°.

The product obtained by the action of zinc on methyl α -bromobutyrate and phenyl styryl ketone in benzene solution when decomposed with acid yields methyl β -hydroxy- β -phenyl- γ -benzylidene- α -ethylbutyrate,

which crystallises in needles, m. p. 117°, and, when heated above its m. p., is resolved into methyl butyrate and phenyl styryl ketone. Decomposition of the product with aqueous sodium carbonate yields benzoyl β -phenyl- α -ethylbutyric acid, $\text{CH}_2\text{Bz}\cdot\text{CHPh}\cdot\text{CHEt}\cdot\text{CO}_2\text{H}$, which crystallises in needles, m. p. 181°, and yields a methyl ester, m. p. 95°.

The lactone, $\text{CHPh}\langle\begin{smallmatrix} \text{CH}=\text{CPh} \\ \text{CMe}_2\cdot\text{CO} \end{smallmatrix}\rangle\text{O}$, obtained by the action of zinc on ethyl α -bromoisobutyrate and phenyl styryl ketone, forms long, colourless needles, m. p. 97°, and is readily hydrolysed by alcoholic potassium hydroxide to γ -benzoyl- β -phenyl- α -dimethylbutyric acid, $\text{CH}_2\text{Bz}\cdot\text{CHPh}\cdot\text{CMe}_2\cdot\text{CO}_2\text{H}$, which crystallises in slender, white needles, m. p. 159—160°. The lactone is accompanied by the ethyl ester of the mentioned acid; this has m. p. 83°, and has also been prepared from the lactone and corresponding acid; the methyl ester has m. p. 92°.

γ -Bromo- γ -benzoyl- β -phenyl- α -dimethylbutyric acid,

prepared by brominating the preceding ketonic acid in chloroform or

carbon tetrachloride solution, forms colourless needles, m. p. 112° (decomp.); the methyl ester, m. p. 125°, and ethyl ester, m. p. 117°, were prepared in a similar manner. When treated with aqueous sodium carbonate the bromo-acid yields two stereoisomeric γ -lactones, β -phenyl- $\alpha\alpha$ -dimethyl- γ -butyrolactones, $\text{CHPh}-\text{CHBr}-\text{CMe}_2\cdot\text{CO}\cdot\text{O}$, which may be

separated by extraction with methyl alcohol. The more soluble modification forms needles, m. p. 113°; the stereoisomeric separates from acetone in needles, having m. p. 173°. When dissolved in cold alcoholic potassium hydroxide and the resulting solution immediately acidified, both isomerides yield a mixture of two stereoisomeric γ -hydroxy γ -benzoyl- β -phenyl- $\alpha\alpha$ -dimethylbutyric acids,

The less fusible of these acids loses water so readily that it could not be obtained free from the lactone of m. p. 173°. The stereoisomeric acid, which forms the major portion of the mixture, separates from ether in needles, m. p. 126° (decomp.); when heated for several hours at 120°, it loses water and is converted into the lactone of m. p. 112°.

Methyl bromomalonate, prepared by the addition of the calculated amount of bromine to methyl malonate, is a colourless, mobile liquid b. p. 145°/22 mm. It reacts with zinc and phenyl styryl ketone in benzene solution, yielding methyl β -benzoyl- α -phenylethylmalonate $\text{CH}_2\text{Br}\cdot\text{CHPh}\cdot\text{CH}(\text{CO}_2\text{Me})_2$. The latter compound crystallises in large, colourless needles, m. p. 107°, and is hydrolysed by alcoholic potassium hydroxide to the corresponding acid (Vorländer, Abstr. 1897, i, 286), which loses carbon dioxide at 170°, yielding γ -benzoyl- β -phenylbutyric acid, m. p. 156°. The preceding ester is accompanied by a viscid liquid, which appears to be a lactonic ester. When hydrolysed with alcoholic potassium hydroxide, this yields the same acid as that obtained by the hydrolysis of methyl β -benzoyl- α -phenylethylmalonate.

F. E.

Crystallographic Study of Potassium *p*-Hydroxybenzoate. ARISTIDE ROSATI (*Atti R. Accad. Lincei*, 1911, [v], 20, ii, 53-54). This substance, prepared by Comanducci and Marcello (Abstr. 1901, i, 485), forms transparent, colourless crystals belonging to the triclinic system [$a:b:c = 0.6471:1:1.7936$].

R. V. S.

***o*-Nitrophenylglyoxylic Acid.** GUSTAV HELLER [with FRIEDRICH FRANTZ and HEINRICH JÜRGENS] (*Ber.*, 1911, 44, 2418-2421). *o*-Nitrophenylglyoxylic acid (compare Claisen and Shadwell, *Ber.*, 1905, 38, 350) is conveniently prepared by oxidation of *o*-nitromandelic acid (Heller and Amberger, Abstr., 1904, i, 416) with alkaline permanganate. It crystallises in colourless, obliquely cut prisms, m. p. 156-157°.

The ethyl ester forms crystals, m. p. 43-44.5°.

The acid is reduced by zinc dust and ammonia to anthroxanic acid; the ester when reduced by stannous chloride and hydrochloric acid converted into ethyl anthroxanate; this crystallises in long, thin needles, m. p. 64-65°.

Methyl anthroxanate forms crystalline bunches, m. p. 70°.

E. F. A.

Keto-enolic Tautomerism. V. Desmotropy of Methyl Acetoacetate. KURT H. MAYER (*Ber.*, 1911, 44, 3739—3739).

Methyl and ethyl acetoacetate contain respectively 16.7% and 21% of enolic modification at the ordinary temperature.

If the methyl ester is dissolved in sodium hydroxide solution and precipitated by dilute sulphuric acid, both strongly cooled, the free acid separates as an oil which solidifies when vigorously shaken; the oil can be dried in an absolute vacuum, but it is soon converted into a mixture of enol and ketone. This behaviour is similar to that of *o*-phenylnitromethane. The enolic form or methyl β -hydroxyacrylate melts indefinitely at 30—40°, and solidifies again when rapidly cooled. The alcoholic solution is coloured intensely reddish-violet by ferric chloride, and also reacts quickly with *anti*-*p*-nitrobenzenediazonium bromide. The crystalline enol, after two hours' drying, contained 84% of the enolic form. In a state of equilibrium at 20°, the ester contained 14% of enol in acetic acid, 21% in alcohol, 56% in carbon disulphide, and 69% in hexane. These numbers are similar to those found with ethyl acetoacetate.

The values of the velocity constants at 0° in absolute alcohol are k_1 (enolisation) = 0.10 and k_2 (enolisation) = 0.04. At the boiling point the alcoholic solution contains only about one-half as much enol as at 0°.

Unlike the equilibrium of ethyl acetoacetate, that of methyl acetoacetate exhibits a distinct temperature-coefficient, the equilibrium being displaced towards the ketone by rise of temperature; the same is the case with acetylacetone, so that the independence of the equilibrium on the temperature is a constitutive property of acetoacetate.

T. H. P.

Preparation of *m*-Hydroxy- β -phenylpropionic Acid Alkyl Esters and their Salts. FARBENFABRIKEN VORM. FRIEDR. BAYER & CO. (R. P. 234852).—*m*-Ethoxy- β -phenylpropionic acid, m. p. 52—53°, d. 205°/20 mm., can be prepared (1) by heating *m*-hydroxy- β -phenylpropionic acid with ethyl bromide and sodium hydroxide in alcoholic solution at 120°; (2) by reducing *m*-ethoxycinnamic acid with sodium amalgam; or (3) by diazotising *m*-amino- β -phenylpropionic acid in anhydrous solvent, isolating the diazonium sulphate with ether, and subsequently boiling it with absolute alcohol; the sodium salt forms colourless powder.

m-Propoxy- β -phenylpropionic acid has m. p. 56—57° and d. 203—204°/15 mm. These compounds have antipyretic and anti-anemic properties.

F. M. G. M.

Few Reactions of Cyanogen and Acyl Cyanides. DANIEL SANDER [and, in part, A. FRIEDNERG, CH. VAN DER MERVE, ROSENTHAL, M. E. HUTH, and M. VON BODECKER] (*Ber.*, 1911, 44, 2455—2476).—The interaction of cyanogen with benzene and its homologues, or with phenolic ethers, yields acyl cyanides, $R\cdot CO\cdot CN$, diacids, $R\cdot CN$, and diketones, $R\cdot CO\cdot CO\cdot R$, together with more complex substances, the constitution of which has not been determined.

When cyanogen is passed into a mixture of benzene and aluminium chloride for one hour at the ordinary temperature, and the product is composed with cold dilute hydrochloric acid, benzoyl cyanide is produced. If the mixture is boiled and the passage of cyanogen continued for four hours, the benzoyl cyanide is accompanied by benzonitrile (Desgrez, Abstr., 1896, i, 419). The product of the reaction always contains a certain amount of a tarry substance, which, on decomposition with acids, yields benzil. The latter compound forms the main product when a mixture of benzene and aluminium chloride is saturated with cyanogen and allowed to remain at the ordinary temperature for three days. In addition to the above compounds, several other substances are formed in the reaction, one of these being a blue dye, m. p. 145—148°.

With respect to the mechanism of the reaction, it is considered that the first stage consists in the formation of an imino-nitrile, which decomposes into benzonitrile and hydrogen cyanide, and on treatment with acids yields benzoyl cyanide, thus:

the formation of benzil is due to the decomposition of a diimino compound (II), produced by the further condensation of the imino-nitrile with benzene:

The interaction of cyanogen, toluene, and aluminium chloride, under conditions similar to those given in the case of benzene, results in the formation of *p*-toluonitrile, *p*-toluic acid, *pp'*-dimethylbenzil, and *p*-methylbenzoyl cyanide (Söderbaum, Abstr., 1893, i, 159).

With ethylbenzene the product consists of *p*-ethylbenzoyl cyanide and *p*-ethylbenzoic acid, together with *p*-ethylbenzoyl cyanide, which could not be isolated, and was therefore identified by conversion into *p*-ethylbenzanilide, m. p. 121°.

The only substance which could be identified in the product obtained from cyanogen and diphenyl was *p*-phenylbenzoyl cyanide.

The action of cyanogen and hydrogen chloride on a solution of phenetole in carbon disulphide in the presence of aluminium chloride yields *p*-ethoxybenzoyl cyanide, which has m. p. 43°, and is more readily prepared by heating *p*-ethoxybenzoyl chloride with mercuric cyanide at 125—130°; it gives a green, and finally blue, solution with strong sulphuric acid, and is decomposed by boiling with dilute hydrochloric acid into *p*-ethoxybenzoic acid and hydrogen cyanide; with aniline it yields *p*-ethoxybenzanilide (Leuckart, Abstr., 1890, 759).

p-Ethoxyphenylglyoxylic acid, obtained by the action of fuming hydrochloric acid on the preceding nitrile, crystallises with water as colourless prisms, m. p. 52°; the anhydrous acid is obtained by crystallisation from benzene, and has m. p. 125° (decomp.); it yields *phenylhydrazones*, $C_{16}H_{18}O_3N_2$, long, yellow needles, m. p. 153° (decomp.) and an *azine*, crystallising in light yellow needles, which have m. p. 173—176°, and simultaneously lose carbon dioxide with the formation of *pp'*-diethoxybenzalazine; the *oxime* has m. p. 152—154° (decomp.). *pp'*-Diethoxybenzil, $C_{18}H_{20}O_4$, prepared by the action of cyanogen and hydrogen chloride on a carbon disulphide solution of phenetole in the presence of aluminium chloride for three to four days, crystallises

ivory-white, microscopic prisms, m. p. 149° , and gives a red coloration with concentrated sulphuric acid. It yields an ozonone, crystallising in small, yellow plates, m. p. 171° , and is converted by alcoholic potassium hydride into *pp'*-diethoxybenzoic acid, which forms narrow prisms, m. p. 302° , with previous darkening.

p-Methoxybenzoyl cyanide, obtained from anisole in the usual manner, crystallises in colourless needles, m. p. 60° ; Mauthner (Abstr., 1909, i, 160) gives $63-64^{\circ}$. It may also be prepared by the interaction of anisoyl chloride and mercuric cyanide; when warmed with acids or alkalis it yields anisic acid.

In view of the above-mentioned formation of benzil from the intermediate product, $\text{NH}\cdot\text{CPh}\cdot\text{CN}$, it was anticipated that the closely related benzoyl cyanide would condense with benzene to form benzil in a similar manner.

It was, however, found that benzoyl cyanide and benzene react at the ordinary temperature in the presence of aluminium chloride and hydrogen chloride, yielding 9-cyanofluorene (Wislicenus and Russ, Abstr., 1910, i, 839), which is converted by heating with fuming hydrochloric or hydriodic acid into 9-fluorene-carboxylic acid. On the other hand, when a mixture of benzene, benzoyl cyanide, and aluminium chloride is heated in carbon disulphide solution, triphenylacetoneitrile (E. and O. Fischer, Abstr., 1879, 326, 385) is produced, $\text{has} : \text{CN}\cdot\text{COPh} + 2\text{C}_6\text{H}_6 \rightarrow \text{CPh}_3\cdot\text{CN} + \text{H}_2\text{O}$.

A number of substituted derivatives of triphenylacetoneitrile has been prepared in a similar manner.

Phenyldi-p-tolylacetoneitrile, $\text{C}_{22}\text{H}_{19}\text{N}$, obtained from benzoyl cyanide and toluene, crystallises in apparently monoclinic prisms, m. p. $33-135^{\circ}$, and is converted by the action of sodium on its alcoholic solution into phenyldi-*p*-tolylmethane (Kliegl, Abstr., 1905, i, 186); it may also be prepared by heating ω -chlorophenyldi-*p*-tolylmethane (Bomberg, Abstr., 1904, i, 489) with mercuric cyanide.

4:4'-Diethyltriphenylacetoneitrile, $\text{C}_{24}\text{H}_{23}\text{N}$, prepared from ethylbenzene and benzoylecyanide, crystallises in colourless plates, m. p. $11-112^{\circ}$.

4:4'-Dimethoxytriphenylacetoneitrile, $\text{C}_{22}\text{H}_{19}\text{O}_2\text{N}$, obtained from anisole, crystallises in short, colourless, rods, m. p. 98° ; it is also obtained in small yield by the interaction of ω -chloro-4:4'-dimethoxytriphenylmethane and mercuric cyanide. When reduced with sodium in alcoholic solution, it yields 4:4'-dimethoxytriphenylmethane (Baeyer and Villiger, Abstr., 1902, i, 380).

4:4'-Dihydroxytriphenylacetoneitrile, $\text{C}_{20}\text{H}_{15}\text{O}_2\text{N}$, prepared by boiling the preceding nitrile with hydriodic acid, forms colourless, hexagonal needles, m. p. 202° ; it is converted by the action of methyl sulphate in alkaline solution into the original nitrile; the *diacetyl* derivative crystallises in colourless leaflets, m. p. 130° . When boiled with phosphorus and hydriodic acid, 4:4'-dimethoxytriphenylacetoneitrile yields 4-hydroxydiphenylacetic acid (Bistrzycki and Flatau, Abstr., 1897, i, 90), which forms an *ethyl* ester, crystallising in stellar aggregates of prisms, m. p. 92° ; the *methyl* ester is an oil.

4-Methoxytriphenylacetoneitrile, prepared from anisoyl cyanide and benzene, crystallises in colourless plates or white needles, m. p. 137° .

4:4'-Diethoxytriphenylacetoneitrile, obtained from benzoyl cyanide and phenetole, forms short, pointed prisms, m. p. 120°; it is converted by heating with hydriodic acid into 4:4'-dihydroxytriphenylacetoneitrile and 4-hydroxydiphenylacetic acid.

Cyanogen and sulphurous acid react slowly in aqueous solution, yielding hydrogen cyanide and sulphuric acid:

F. R.

Condensation of *p*- and *o*-Methoxymandelonitriles with Phenols and Phenolic Ethers. AUGUSTIN BISTRZYCKI, J. PATEL and R. PERRIN (*Ber.*, 1911, 44, 2596—2617).—The paper contains merely a description of the following substances, and has been published in consequence of Stoermer and Hildebrandt's recent work (this vol., i, 664).

o- and *p*-Methoxymandelonitriles condense like the corresponding acids with phenols or phenolic ethers in the presence of 73% sulphuric acid, yielding nitriles of the type $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CHAr}\cdot\text{CN}$; thus anisaldehydecyanohydrin (1 mol.) and phenol (2½ mol.) yield 4-hydroxy-4'-methoxydiphenylacetoneitrile, $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}(\text{CN})\cdot\text{C}_6\text{H}_4\cdot\text{OH}$, prismatic needles, m. p. 175—176° (erroneously described by Stoermer and Hildebrandt as the lactone of *o*-hydroxyphenylacetic acid), which forms an acetyl derivative, m. p. 85.5—86.5°, and is hydrolysed by boiling alcoholic potassium hydroxide, forming 4-hydroxy-4'-methoxydiphenylacetic acid (*p*-hydroxyphenylanisylacetic acid), m. p. 148.5—149.5°. This acid does not yield a lactone (consequently the hydroxyl group is assumed to be in the para-position), and evolves two-thirds of the theoretical quantity of carbon monoxide when heated with concentrated sulphuric acid at 170° (compare Bistrzycki and Siemiradzki, *Abstr.*, 1908, i, 635). Anisaldehydecyanohydrin and *o*-cresol yield in a similar manner 4-hydroxy-4'-methoxy-3-methyldiphenylacetoneitrile, m. p. 142—143° (acetyl derivative, m. p. 74.5—76°); the corresponding acid, m. p. 128—129°, loses two-thirds of the theoretical quantity of carbon monoxide with sulphuric acid at 100—120°. The lactone of *p*-hydroxytolylanisylacetic [2-hydroxy-4'-methoxy-5-methyldiphenylacetic acid (Stoermer and Hildebrandt, *loc. cit.*) is hydrolysed by 6% potassium hydroxide to the corresponding acid, m. p. 110° (decomposes), which exhibits considerable stability for a γ -lactone. The lactone is converted into 2-hydroxy-4'-methoxy-5-methyldiphenylacetamide, decomp. 137.5°, by 25% aqueous ammonia and a little alcohol, and into the hydrazide, $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}(\text{CO}\cdot\text{NH}\cdot\text{NH}_2)\cdot\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{OH}$, decomp. 182.5° (benzylidene derivative, m. p. 184°), in boiling alcohol by 50% aqueous hydrazine hydrate.

Anisaldehydecyanohydrin and catechol condense to form 3:4-dihydroxy-4'-methoxydiphenylacetoneitrile,

m. p. 153.5—154.5°, darkening at 130° (diacetate, m. p. 77—78°, which develops a blue, and by warming a bluish-violet, coloration with concentrated sulphuric acid. Anisaldehydecyanohydrin and β -naphthol yield the lactone of 2-hydroxy- $\alpha(1)$ -naphthyl-4-methoxyphenyl-

acid, $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{OH} \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{C}_6\text{H}_4 \end{array} \text{O}$, m. p. 145—146° (decomp.),

prismatic needles.

o-Anisaldehydecyanohydrin condenses very readily with anisole to form *dimethoxyacetanitrile* [4:4'-dimethoxyphenylacetanitrile], $\text{CN} \cdot \text{CH}(\text{C}_6\text{H}_4 \cdot \text{OMe})_2$,

m. p. 154—5°. *o*-Anisylacetic acid reacts readily with phosphorus pentachloride and phosphoryl chloride to form the *chloride*, $\text{H}(\text{C}_6\text{H}_4 \cdot \text{OMe})_2 \cdot \text{COCl}$, m. p. 58—61°. In a similar manner anisole yields *anisylphenylacetanitrile*, m. p. 87—88°, whilst *p*-cresol yields 3:4:4'-trimethoxydiphenylacetanitrile, m. p. 96°, the corresponding acid having m. p. 154—155°.

o-Anisaldehydecyanohydrin (rhombic crystals, $a:b:c = 0.652:1:0.462$) condenses less readily than the *para*-isomeride with anisole, except *p*-cresol. The lactone of 2-hydroxy-2'-methoxy-6-methyl-

phenylacetic acid, $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{CH} \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{C}_6\text{H}_4 \cdot \text{Me} \end{array} \text{O}$, m. p. 136°, obtained

directly from the cyanohydrin and *p*-cresol with 73% sulphuric acid in the water-bath, is hydrolysed to the acid, $\text{C}_{18}\text{H}_{16}\text{O}_4 \cdot \text{H}_2\text{O}$, m. p. 172°, by 6% potassium hydroxide, to the *amide*, $\text{C}_{16}\text{H}_{17}\text{O}_3\text{N}$, decomp. 177—178°, by alcoholic ammonia at 100°, to the *anilide*, m. p. 192—194°, by distillation with aniline, and to the *hydrazide*, m. p. 154° (*benzylidene* derivative, m. p. 202°), by hydrazine hydrate.

The condensation of *o*-anisaldehydecyanohydrin and *o*-cresol yields a mixture of 4-hydroxy-2'-methoxy-3-methyldiphenylacetamide (prisms containing $\text{C}_6\text{H}_4\text{O}_2$, m. p. 130—131°, from acetic acid) and the isomer of 4-hydroxy-2'-methoxy-3-methyldiphenylacetic acid, m. p. 164°. The cyanohydrin and phenol likewise yield a mixture of the lactone of 4-hydroxy-2'-methoxydiphenylacetic acid, m. p. 160—162°, and 4-hydroxy-2'-methoxydiphenylacetamide, m. p. 204—205°, which is hydrolysed slowly and incompletely by boiling concentrated potassium hydroxide.

C. S.

Diphenyl Derivatives. FRITZ MAYER (*Ber.*, 1911, 44, 2298—2305).—The following substances were obtained in the course of attempts to synthesise pyrene by using Ullmann's method for the preparation of *s*-diphenyl derivatives (*Abstr.*, 1901, i, 586).

2-Acetylaminoisophthalic acid, prepared by Noeltling and Gachot's method (*Abstr.*, 1906, i, 181), is best purified by heating with acetic anhydride, which gives rise to the corresponding *acetylanthranyl*, m. p. 217—218°; the latter is readily re-converted into the acid by crystallisation from water. The acid softens at 195—200° and decomposes at 205—206°, and when warmed with diluted sulphuric acid yields 2-aminoisophthalic acid. The latter, on diazotisation and treatment with iodine in potassium iodide solution, gives 2-iodoisophthalic acid, m. p. 205—222° (decomp.), with some of the corresponding hydroxy-acid, from which it is best separated by conversion into the *methyl* ester, m. p. 50°, long, colourless needles. The latter, when heated with copper powder at 140—150°, yields *diphenyl-1:6:2':6'-tetracarboxylic acid*, iridescent leaflets, melting above 350°, in the form of the *tetramethyl* ester, m. p. 125—126°, which crystallises

in colourless needles. The corresponding acid chloride, $C_{10}H_7O_2Cl$, m. p. 189—190°, obtained as a brittle mass by precipitation with light petroleum from benzene, does not yield pyrene on reduction with the usual agents, and when heated with copper gives an amorphous, red substance.

2-Iodo-m-toluic acid, m. p. 145—146°, prepared from the corresponding methyl aminotoluate (Müller, Abstr., 1909, i, 156) by diazotising, adding potassium iodide, and hydrolysing the methyl ester, b. p. 280—290°, so obtained, crystallises in needles from benzene or methyl alcohol. When heated with copper powder at 220°, it yields 2:2'-dimethyldiphenyl-6:6'-dicarboxylic acid, which crystallises from ether on addition of light petroleum, sinters strongly, and finally melts at 230°. The yield is small.

Methyl o-iodocinnamate, m. p. 65°, crystallises in silky, yellow needles, and does not yield pyrene when heated with copper powder.

o-Iodobenzaldehyde may be readily identified by condensing it with aniline, when it yields o-iodobenzylideneaniline, m. p. 75—76°, crystallising from methyl alcohol in colourless needles. When heated with copper powder at 210—220°, o-iodobenzaldehyde furnishes 2:2'-dialdehydodiphenyl as a viscous, brown oil with an odour similar to that of benzaldehyde; the dioxime, m. p. 175—176°, crystallises from methyl alcohol in yellow needles. The dialdehyde, when heated with acetic anhydride and sodium acetate, is converted into diphenyl-2:2'-diacrylic acid, m. p. 286° (decomp.), which crystallises from acetic acid, yields diphenic acid on oxidation with dilute alkaline permanganate, and when distilled alone or with lime, lead oxide, or zinc dust, gives an oily substance which slowly deposits a small amount of crystalline matter from which a picrate, m. p. 140°, can be obtained. T. A. H.

Simultaneous Reduction and Oxidation by Catalysis. NICOLAI ZELINSKY and NIKOLAUS GLINKA (Ber., 1911, 44, 2305—2311*).—Methyl Δ^1 -tetrahydroterephthalate, dissolved in dry ether, when treated with palladium black in presence of a current of hydrogen at atmospheric temperature furnishes a mixture of methyl terephthalate and methyl cis-hexahydroterephthalate. The same change takes place, but more slowly, with platinum black. The oxidation is not due to oxygen occluded by palladium, since it does not occur in absence of hydrogen. The mechanism of the reaction may be that the tetrahydroterephthalate is immediately reduced in part by the palladium in virtue of hydrogen occluded by the latter, the hydrogen thus lost by the palladium being recovered from the residual tetrahydroterephthalate, so that a re-distribution of the hydrogen in 3 mols. of the tetrahydroterephthalate occurs thus: $3C_{10}H_{14}O_4 = 2C_{10}H_{16}O_4 + C_{10}H_{10}O_4$; or, as suggested by Bach (Abstr., 1910, ii, 31), a labile palladium perhydride may be formed, which reacts with an oxyperhydride, OH_2 , momentarily formed, in which, under the influence of palladium perhydride, the normal affinity of oxygen in the molecule of water is so distributed as to hold 4H in place of 2H. The existence of such an intermediate product would explain (1) the simultaneous occurrence of oxidation and reduction of

* and J. Russ. Phys. Chem. Soc., 1911, 43, 1084—1091.

instance; (2) Ipatieff's observation that in catalytic reduction at low pressures the presence of oxygen favours the action, and (3) that Sabatier's nickel reduction method, nickel prepared at 200–250°, which temperature it may still contain oxygen, gives the best results. The palladium black used in these experiments was obtained by adding first formic acid and then alkali to an aqueous solution of palladium ammonium chloride.

T. A. H.

[Preparation of Dichloro-*o*-carboxyphenylthiolacetic Acid.]
MILLS & Co (D.R.-P. 234375).—When the di- or tri-halogenated *o*-carboxyphenylthiolacetic acid neutral esters are treated with sodium hydroxide, they yield the corresponding halogenated oxythionaphthene-carboxylic acid esters, which are then hydrolysed and the resulting product oxidised to dyes.

Dichloro-*o*-carboxyphenylthiolacetic acid, $\text{CO}_2\text{H}\cdot\text{C}_6\text{H}_3\text{Cl}_2\cdot\text{S}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, colourless, colourless needles, was prepared as follows: Aceto-*o*-toluidide was dichlorinated, oxidised with potassium permanganate to dichloro-*o*-anthranilic acid, the acetyl group eliminated, and the dichloro-*o*-anthranilic acid so obtained, diazotised and converted into either a dichloro-*o*-thiolbenzoic acid or a xanthate derivative, which on subsequent treatment with chloroacetic acid yielded the foregoing acid. Esterification was carried out in the usual way, and the ring subsequently closed by heating at 40–50° with concentrated sodium hydroxide, yielding ethyl dichloro-3-oxy-(1)-thionaphthene-carboxylate, which was not isolated but hydrolysed by dilution and prolonged boiling. Subsequent oxidation with potassium ferricyanide (or air) furnished a dye which was isolated as a dark violet powder.

F. M. G. M.

Action of Organo-magnesium Compounds on 4-Methoxyphthalic Anhydride. HUGO BAUER (*Arch. Pharm.*, 1911, 249, 450–453).—It has been shown previously (Abstr., 1908, i, 274) that the nitro group in nitrodiethylphthalide (Abstr., 1904, i, 417) probably occupies position 5, and to confirm this an attempt was made to synthesise 5-methoxydiethylphthalide, which was prepared from the nitro compound as described already (Abstr., 1908, i, 274). By the action of magnesium ethyl bromide on 4-methoxyphthalic anhydride, either 4- or 5-methoxydiethylphthalide might be formed, and trial proved that the former only was produced.

4-Methoxydiethylphthalide, $\text{OMe}\cdot\text{C}_6\text{H}_3\cdot\left\langle\begin{smallmatrix} \text{C} & \text{CF}_2 \\ & \text{O} \end{smallmatrix}\right\rangle$, m. p. 86–87°, crystallises from dilute alcohol in colourless prisms. On fusion with potassium hydroxide, it furnishes anisic acid, and on nitration gives only a mononitro-derivative, m. p. 117°, which crystallises from alcohol in faintly yellow needles. On reduction with iron and acetic acid at 100°, this gives the corresponding amino-compound, m. p. 163°, which crystallises from dilute alcohol in colourless leaflets or prisms. It fluoresces blue in alcohol solution.

T. A. H.

Action of Organo-magnesium Compounds on Homophthalic Anhydride. HUGO BAUER and EWALD WÜLZ (*Arch. Pharm.*, 1911, 249, 454–458. Compare Abstr., 1904, i, 417; 1905, i, 210; 1909, i, 585, and preceding abstract).—The previous work (*loc. cit.*)

has shown that the normal action between organo-magnesium compounds and dicarboxylic anhydrides gives rise to dialkylphthalides, but in certain cases other reactions occur, such as the formation of *o*-diketones or the production of monoalkylphthalides. This condensation has therefore been further investigated with homophthalic anhydride in place of phthalic anhydride. The former may give rise to dialkyl derivatives of either type represented by the formulae:

The former type should yield on fusion with potassium hydroxide, and assuming R to be Me, acetone and phenylacetic acid, while the second should give acetone and *o*-toluic acid. Application of this reaction to the condensation products gave unexpected results, so that at present constitutional formulae cannot be assigned to them.

Dimethylhomophthalide, $\text{C}_{11}\text{H}_{12}\text{O}_2$, m. p. 94–95°, obtained by condensing magnesium methyl iodide with homophthalic anhydride and treating the product with dilute acid, crystallises from hot ether as slender, colourless needles, dissolves in warm alkalis, and is reprecipitated by acids, does not react with hydroxylamine or ammonia, and fluoresces green when warmed with sulphuric acid.

Diphenylhomophthalide, $\text{C}_{21}\text{H}_{16}\text{O}_2$, m. p. 160–161°, similarly prepared, crystallises from alcohol, and resembles the foregoing substance in properties, but gives an orange-red to brownish-red coloration with sulphuric acid.

Dibenzylhomophthalide, $\text{C}_{23}\text{H}_{20}\text{O}_2$, m. p. 163–164°, crystallises from alcohol, and gives a wine-red coloration with sulphuric acid.

T. A. H.

Phthaleins of 3:5:3':5'-Diresorcinol (3:5:3':5'-Tetrahydroxydiphenyl). RICHARD MEYER and KARL MEYER (*Ber.*, 1901, 44, 2678–2684).—The soluble phthalein obtained by Benedikt and Julius (Abstr., 1884, 1139; compare also Link, *ibid.*, 1881, 93) by the condensation of phthalic anhydride and 3:5:3':5'-tetrahydroxydiphenyl in the presence of concentrated sulphuric acid has, according to the authors, the annexed constitution.

When warmed with acetic anhydride and a little sulphuric acid, it yields a *tetraacetate*, which forms long, flat, rhomb-shaped crystals, m. p. 237–238°; the *tetraacetate* crystallises in stout, prismatic needles, m. p. 180–181°. The *tetramethyl ether*, $\text{C}_{20}\text{H}_{16}\text{O}_2(\text{OMe})_4$, obtained by the action of methyl sulphate in alkaline solution, forms colourless needles; the *diethyl ether*, prepared by alkylating the phthalein

either with ethyl iodide and sodium ethoxide in alcoholic solution, or by means of ethyl sulphate in alkaline solution, crystallises in flat needles or leaflets, m. p. 223°. When brominated in glacial acetic acid solution the phthalein yields a *tribromo-derivative*, $\text{C}_{20}\text{H}_{13}\text{O}_2\text{Br}_3$, crystallising in slender needles.

The insoluble phthalein, obtained by Benedikt and Julius (*loc. cit.*),

is best prepared by the condensation of 1 mol. of phthalic anhydride with 2 moles. of 3:5:3':5'-tetrahydroxydiphenyl in the presence of concentrated sulphuric acid at 120°. It has no m. p., dissolves in alkalis with a blue coloration, and is considered to be a hexahydroxy-

diphenylfluoran of the annexed constitution. It yields a *hexabenzosulphate*, crystallising in broad leaves, m. p. 245—250°; the *hexaethyl ether*, prepared by means of ethyl sulphate, crystallises in needles, m. p. 234—236°.

4:4' (or 2:2')-Bisbenzenesazo-3:5:3':5'-tetrahydroxydiphenyl,
 $\text{NPh}\cdot\text{N}\cdot\text{C}_6\text{H}_4(\text{OH})_2\cdot\text{C}_6\text{H}_4(\text{OH})_2\cdot\text{N}\cdot\text{NPh}$,

obtained by the combination of benzenediazonium chloride and 3:5:3':5'-tetrahydroxydiphenyl in alkaline solution, crystallises in stout, red needles having a steel-blue lustre.

4:4' (or 2:2')-Bis-*p*-toluenesazo-3:5:3':5'-tetrahydroxydiphenyl,
 $\text{C}_{12}\text{H}_8\text{O}_4(\text{N}_2\cdot\text{C}_6\text{H}_4)_2$,

prepared in a similar manner, forms slender, red needles. F. B.

Synthesis of Chrysene. ERICH BESCHKE [with MARIAM WINOGRADSKANAL and GEORG KOHRES] (*Annalen*, 1911, 384, 143—172).—The interaction of benzil, ethyl bromoacetate, and zinc in boiling benzene led to the formation of the racemic and meso-modifications, m. p. 37° and 168° respectively, of *ethyl βγ-dihydroxy-βγ-diphenyladipate*, $\text{Et}\cdot\text{CH}_2\cdot\text{CPh}(\text{OH})\cdot\text{CPh}(\text{OH})\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$, which are separated by the insolubility of the latter in cold benzene. When boiled with zinc and concentrated hydrochloric acids, or heated above its m. p., the racemic modification is easily converted into the *di-lactone*, $\text{Ph}\cdot\text{CH}_2\cdot\text{CPh}(\text{OH})\cdot\text{CPh}(\text{OH})\cdot\text{CH}_2\cdot\text{CO}$, m. p. 194°, which is being examined.

The meso-modification forms a *diacetyl* derivative, m. p. 171°, and is hydrolysed by boiling 10% sodium hydroxide, yielding the *sodium salt*, $\text{C}_{24}\text{H}_{18}\text{O}_6\text{Na}_2\cdot 10\text{H}_2\text{O}$, from which a stable, sparingly soluble *silver salt*, $\text{C}_{24}\text{H}_{16}\text{O}_6\text{Ag}_2\cdot 3\text{H}_2\text{O}$, has been prepared. The anhydrous silver salt is converted into silver, carbon dioxide, and acetophenone by distillation, and regenerates the meso-ester with ethyl iodide. *βγ-Dihydroxy-βγ-diphenyladipic acid*, m. p. 205°, obtained from the sodium salt and glacial acetic acid, is converted by alcoholic hydrogen chloride, not into the original meso-ester, but into *ethyl β-hydroxy-βγ-diphenylbutyrolactone-γ-acetate* [3-hydroxy-5-keto-2:3-diphenyltetrahydrofuran-2-acetate], $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{CPh}\cdot\text{CPh}(\text{OH})\cdot\text{CH}_2\cdot\text{CO}$, m. p. 138°, which is also obtained by adding a little concentrated hydrochloric acid to a dilute concentrated solution of the meso-ester in glacial acetic acid. *β-Hydroxy-βγ-diphenylbutyrolactone-γ-acetic acid*, $\text{C}_{18}\text{H}_{16}\text{O}_6$, m. p. 179°, is obtained by the action of acetic acid and a mineral acid on its ethyl

ester or on β -dihydroxy- β -diphenyladipic acid, but by too prolonged action the former method yields β -diphenylcrotonolactone- γ -acetic [5-keto-2:3-diphenyl-2:5-dihydrofuran-3-acetic] acid,

m. p. 184°. This acid, however, in the form of its ethyl ester, m. p. 94°, is more easily obtained by treating the above-mentioned meso-ester in acetic anhydride with concentrated sulphuric acid below 40–50°.

When ethyl β -diphenylcrotonolactone- γ -acetate is treated with boiling alcoholic sodium hydroxide (not in excess), the sodium salts of two acids are obtained. One of these acids is the monoethyl ester of β -diphenylmuconic acid, $\text{CO}_2\text{H}\cdot\text{CH}\cdot\text{CPh}\cdot\text{CPh}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$, m. p. 140°, which lactonises to the original ester when boiled with acetic acid. The other acid is β -diphenylmuconic acid, which, however, cannot be isolated, since it at once changes to β -diphenylcrotonolactone- γ -acetic acid when liberated from its sodium salt. Diethyl β -diphenylmuconate, m. p. 72°, obtained from the silver salt of either of the two acids and ethyl iodide, reacts with bromine in chloroform in sunlight to form a substance, $\text{C}_{20}\text{H}_{17}\text{O}_4\text{Br}$, m. p. 143°, which probably has the constitution

When aqueous sodium β -diphenylmuconate is treated with acids in potassium iodide and the solution is acidified after prolonged keeping, β -diphenylcrotonolactone- γ -iodoacetic acid,

m. p. 217°, is obtained, which is reduced by zinc and acetic acid to β -diphenyl- α -dihydromuconic acid, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CPh}\cdot\text{CPh}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, m. p. 297°. This acid is best obtained by reducing sodium diphenylmuconate with sodium amalgam, whereby an acidic by-product, $\text{C}_{18}\text{H}_{16}\text{O}_4$, m. p. 195° (ethyl ester, m. p. 56°), is also formed, which is easily soluble in alcohol. Diphenyldihydromuconic acid forms as

ethyl ester, m. p. 86°, and is converted by acetic anhydride and concentrated sulphuric acid into the di-acetate, m. p. 246°, of 2:8-dihydroxychrysene (annexed constitution), which is itself obtained by hydrolysing the diacetate by trituration with cold concentrated sulphuric acid. 2:8-Dihydroxychrysene yields yellow solutions in alkalis becoming blue in the air, forms a diethyl ester, m. p. 207°, and a dibenzoate, m. p. 280°, and is reduced to chrysene by distillation with zinc dust.

Methylcarbonato-derivatives of Phenolcarboxylic Acids and their Use for Synthetic Operations. V. EMIL FISCHER and KARL FREUDENBERG (*Annalen*, 1911, 384, 225–244. Compare Abstr., 1910, i, 265).—Didepsides of the more important di- and tri-hydroxybenzoic acids have been prepared on account of their relation to many natural products.

Dimethylcarbonatodigenticic acid, $C_{18}H_{16}O_{11}$, m. p. 166—167° (corr.), colourless, flexible needles, is obtained by shaking a mixture of 3-methylcarbonato-2-hydroxybenzoic acid, dimethylaniline, benzene, and phosphorus trichloride for three days at the ordinary temperature; its alcoholic solution develops a deep red coloration with ferric chloride.

Digenticic acid (annexed constitution), m. p. 208—209° (corr.), is obtained by hydrolysing the preceding compound by *N*-ammonia at 18—20° in an atmosphere of hydrogen. In contrast to gentiic acid, it precipitates dilute solutions of albumin or quinine acetate, and develops a transient, blue coloration with ferric chloride. *Dimethylcarbonatodi-β-resorcylic acid*, $C_{18}H_{16}O_8$, m. p. 13—164° (corr.), obtained from 4-methylcarbonato-2-hydroxybenzoic acid by a modification of the preceding process, yields by hydrolysis *β-resorcylic acid*, $C_6H_2(OH)_2 \cdot CO \cdot O \cdot C_6H_3(OH) \cdot CO_2H$, m. p. 215° (corr., decomp.).

3-Methylcarbonato-4-hydroxybenzoic acid, $CO_2Me \cdot O \cdot C_6H_3(OH) \cdot CO_2H$, m. p. 176° (corr., decomp.), obtained by the partial hydrolysis of the methylcarbonatobenzoic acid (Abstr., 1908, i, 892), is converted to isovanillic acid by treatment with diazomethane and subsequent hydrolysis. When treated in acetone with *N*-sodium hydroxide and 4-dimethylcarbonatobenzoyl chloride in an atmosphere of hydrogen, yields, after hydrolysis of the product, *diprotocatechuic acid*, $H_2(OH)_2 \cdot CO \cdot O \cdot C_6H_3(OH) \cdot CO_2H$, m. p. 237—239° (corr., decomp.). *Dipallic acid*, $C_{14}H_{10}O_8$, m. p. 282° (corr., decomp.), is obtained in a similar manner to the preceding acid; it precipitates solutions of albumin and of quinine acetate, and develops the usual bluish-black coloration with ferric chloride.

The following depsides have been prepared by similar methods. [With KURT HOESCH.]—*Diferulic acid*, m. p. 241—242°; *di-ommuric acid*, m. p. 188—190°; *di-β-hydroxynaphthoic acid*, m. p. 15°; *4-feruloyloxybenzoic acid*, m. p. 233°; *4-α-hydroxynaphthoylbenzoic acid*, m. p. 246—247°. [With R. LEPSIUS.]—*Diayringic acid*, m. p. 260°; *di-m-hydroxybenzoic acid*, m. p. 199°; *4-syringoylbenzoic acid*, m. p. 208°; *p-hydroxybenzoylsyringic acid*, m. p. 12—284°; *4-m-hydroxybenzoyloxybenzoic acid*, m. p. 239—240°; *p-hydroxybenzoyloxybenzoic acid*, m. p. 254°. C. S.

p-Cresolglycuronic Acid. CARL NEUBERG and E. KEETSCHMER (chem. Zeitsch., 1911, 36, 15—19).—Phenols excreted in the urine are never found in the free state, but as derivatives of glycuronic and sulphuric acids.

p-Cresol given to dogs was found to be excreted as a *p*-cresol derivative of glycuronic acid, $C_6H_9O_7 \cdot O \cdot C_6H_4Me$, and as *p*-tolyl hydrogen sulphate.

A barium salt was isolated from the urine, which proved to be a mixed salt of these two acids. W. J. Y.

Cherry-laurel Water and Solutions of Benzaldehyde and hydrocyanic Acid in Water. P. H. WINTU (Arch. Pharm., 1911, 49, 382—407).—An investigation of the equilibrium point reached

in aqueous solutions of benzaldehyde, benzaldehydecyanohydrin, and hydrogen cyanide under various conditions of temperature, concentration, acidity, alkalinity, etc., with special reference to the determination of the usual composition of cherry-laurel water (compare Dege, Abstr., 1894, ii, 165; Fromm, Abstr., 1898, i, 266). The following points are established: All three compounds co-exist in aqueous solution, and the same equilibrium is reached whether the cyanohydrin or its two components be initially added to water. With increasing concentration, the equilibrium point moves in the cyanohydrin direction, and vice versa. The cyanohydrin is progressively dissociated into its components with rise of temperature. Alkali in small quantities accelerate the rate at which equilibrium is reached, and cause dissociation of the cyanohydrin, but even in presence of considerable quantities of alkali the cyanohydrin is never completely dissociated (compare Ulée, Abstr., 1906, i, 5, and Rosenthaler, Abstr., 1909, i, 623). Equilibrium is reached less quickly in presence of acids. Silver nitrate produces silver cyanide in these solutions in presence of alkali, and the whole of the hydrogen cyanide may be thus removed, but in presence of acids the equilibrium is more stable, except under the influence of change of temperature or concentration. The toxicity of benzaldehydecyanohydrin is proportional to the amount of hydrocyanic acid it can yield on dissociation. T. A. H.

Hydrogenation of Hydroaromatic Compounds. VERN SKWORZOW (*J. pr. Chem.*, 1911, [ii], 84, 422—424).—The usual method of reduction when applied to hydroaromatic ketones either fails or give poor results. The author finds that the reduction may be effected quite easily, and with almost quantitative yield, by means of sodium and alcohol, if carried out under pressure in an autoclave. *l*-Menthone yields by this method a mixture of solid and liquid dextrorotatory menthols, whilst from *d*-pulegone a levorotatory mixture was obtained. P. E.

Ketens. V. Reactivity of the Carbonyl Group. HERMANN STAUDINGER and N. KON (*Annalen*, 1911, 384, 38—135. Compare this vol., i, 462).—Previous experiments have shown that diphenylketene reacts with carbonyl compounds to form β -lactones or their products of decomposition, carbon dioxide and ethylene derivatives (Abstr., 1908, i, 410, 411; this vol., i, 459), and have demonstrated, although not conclusively, on account of complications introduced by side reactions, that the reactivity of the carbonyl group is strongly influenced by the neighbouring substituents (Abstr., 1910, i, 46). The present paper describes an exhaustive examination of this influence. The efficacy of the method of examination previously employed (Abstr., 1910, i, 46) has been tested by experiments with benzophenone or fluorenone, with these ketones side reactions are not possible. It is found that with these ketones side reactions are not possible. It is found that with molecular quantities, 1:1 or 1:10, of the ketone and diphenylketene (in the form of the solid diphenylketene-quinoline) at 131°, the expressions $x/(a-x)$ or $1/t \cdot \log a/(a-x)$ respectively are approximately constant during the first hour; subsequently their value diminishes probably owing to the gradual polymerisation of the diphenylketene.

maline. (It has been found that extensive polymerisation of diphenylketen-quinoline occurs even at 131° in the presence of these substances which catalytically accelerate the process. The pyrazole does not react with carbonyl compounds.) Consequently, in the experiments with other carbonyl compounds, the amount of carbon dioxide evolved at the end of the first hour is taken as a measure of the reactivity of the carbonyl group, of course provided at the approximate constancy, during this interval, of one or other of the preceding expressions, according to the relative quantities of the carbonyl compound and diphenylketen employed, has afforded evidence that side-reactions have not occurred to an extent sufficient to modify the results.

The influence of a number of like substituents on different carbonyl-containing groups has been examined in order to compare the activity of the carbonyl group in aldehydes, ketones, and acid derivatives. In the formula $R \cdot CO \cdot R'$, R is (I) Ph, (II) $OMe \cdot C_6H_4$, (III) $NMe_2 \cdot C_6H_4$, (IV) $CHPh \cdot CH$, thus giving four series of phenyl compounds. The figures in the following list give, for several R' 's, the percentage amount of the ketone which enters into a reaction during the first hour: $R' = CHPh \cdot CH$, I. 31.4, II. 32.2, III. 32.3, IV. 69.0; $R' = H$, I. 3.8, II. 17.8, III. 53.0, IV. 38.3; $R' = CN$, I. 2.2, IV. 52.6; $R' = Ph$, I. 1.4, II. 4.2, III. 37.8, IV. 31.4; $R' = Me$, I. 2.2, II. 4.9, III. 11.4, IV. 16.3; $R' = NMe_2$, I. 2.5, II. 2.5, III. 12.2, IV. 11.4; $R' = NPh_2$, I. 2.5, IV. 4.8; $R' = OMe$, I. 0.2, II. 1.1, III. 4.0, IV. 1.3; $R' = Cl$, I. 0.2, II. 0.2, III. 1.6, IV. 4.0. Unfortunately, the results do not allow any definite conclusions to be drawn as to the influence of R and R' on the activity of the carbonyl group, because the k of a unimolecular or bimolecular reaction is only approximately constant when $R = Ph$ or $OMe \cdot C_6H_4$, and not at all constant in the other two series. However, several points are clearly indicated. Firstly, the reactivity of the carbonyl group is very differently influenced by different R' 's in the four series, but always in the same direction. Secondly, the reactivity of the carbonyl group is greatest in the neighbourhood of the styryl group and least in the acid chlorides and esters. Finally, compounds containing the benzoyl group are more reactive than those containing the benzoyl group.

The authors show that the varying reactivity of the carbonyl group cannot be explained by steric influences or by an increase or decrease in the basic character of the carbonyl group caused by the neighbouring groups, but attribute it to the varying degree of unsaturation of the carbonyl group; the greater the unsaturation of the group, the greater is its reactivity with diphenylketen. This leads them to a conclusion which is emphasised throughout the paper. Since chromophores are unsaturated groups, the more unsaturated the carbonyl group the more chromophoric is its character. In their experiments the authors have observed that the carbonyl group in a coloured compound is more unsaturated (that is, more reactive) than that in a colourless compound of similar structure; moreover, influences which intensify the colour of a carbonyl compound also increase the unsaturation of the carbonyl group. A general review of these and of

previous experiments shows that quinones and unsaturated ketones react most energetically with diphenylketen, then come, in order of decreasing reactivity, aldehydes, aromatic ketones, and acid derivatives; it is the first two classes of compounds which are most prone to exhibit colour.

The reactivity of the carbonyl group in a series of compounds containing the cinnamoyl group cannot be compared by the amount of carbon dioxide evolved, because the reaction proceeds in two directions, thus diphenylketen and phenyl styryl ketone react:

(this δ -lactone was previously stated to be 3-benzoyl-1:1:2-cyclopent-4-cyclobutanone, Abstr., 1910, i, 46).

The great reactivity of the whole conjugated system in phenyl styryl ketone is very remarkable in contrast with the slight reactivity of benzaldehyde and of styrene with diphenylketen. In the case of the C:C:C:O system, the addition of diphenylketen occurs at the position 1:4 the more the carbon atom 4 is rendered unsaturated by neighbouring substituents; addition in the position 1:2 predominates when the oxygen atom is rendered more unsaturated in the "crossed" conjugate system, $\begin{array}{c} \text{C:C} \\ \text{C:C} \end{array} \text{C:O}$, the distribution of the

residual affinity is such that the oxygen is particularly unsaturated, consequently the addition of diphenylketen occurs very largely at the carbonyl group. For example, phenyl styryl ketone and diphenylketen react to the extent of 87% in the 1:2 position and 63% in the 1:4, whilst in the case of distyryl ketone the values are 71 and 29 respectively.

It is found, in general, that compounds containing a conjugated system are more reactive than those with a simple double bond, and that substances with a "crossed" system of double linkages are particularly unsaturated. Here again a parallelism is to be observed between unsaturation and colour; substances containing a conjugated system are more coloured than similar substances which do not have colour being especially intense when a "crossed" conjugate system is present.

A similar parallelism is observed in the case of pyrone and pyrone-quinone; pyrones react very slightly with diphenylketen, while the quinones exhibit the greatest reactivity.

One of the most important points in the paper is the examination of the influence of auxochromic groups on the reactivity of a carbonyl group. (The auxochrome must be present as OR or NR₂ and diphenylketen attacks the hydroxyl or amino-group in preference to the carbonyl group.) A study of the preceding list of compounds of the type R·CO·R' shows that the methoxy-group, and particularly the dimethylamino-group, increases the reactivity of the carbonyl group.

influence is greatest in the ortho-, and least in the meta-, position. As it is well-known that auxochromes intensify colour, the relationship between colour and unsaturation is manifested once again. The introduction of an acyl group into the hydroxyl or amino-group (which weakens the colour of the substance) causes a diminution in the reactivity of the carbonyl group.

Several other points, such as Kauffmann's inversion of chromophores and an explanation of the action of auxochromic groups, are covered in the light of the theory that the reactivity of a group is dependent on its degree of unsaturation.

The following new compounds are described. The great majority of them have been obtained by the decomposition at 130–153° of the same compound of diphenylketene and a carbonyl compound. *p*-chlorotriphenylethylene, $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{CH} : \text{CPh}_2$, m. p. 81–82°, white crystals; *p*-dimethylaminotriphenylethylene, $\text{NMe}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CH} : \text{CPh}_2$, m. p. 126–127°, autoxidisable, yellow or yellowish-green crystals; *p*-tolylethylene, $\text{CPh}_2 \cdot \text{CPh} \cdot \text{C}_6\text{H}_4\text{Me}$, m. p. 153°; diphenylideneethylene, $\text{CPh}_2 \cdot \text{C}(\text{C}_6\text{H}_4 \cdot \text{OMe})_2$, m. p. 159–160°, colourless crystals; *p*-dimethylaminotetraphenylethylene, $\text{NMe}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CPh} : \text{CPh}_2$, m. p. 173°; tetramethyl-*pp'*-diaminotetraphenylethylene, $\text{CPh}_2 \cdot \text{C}(\text{C}_6\text{H}_4 \cdot \text{NMe}_2)_2$.

m. p. 211–212°, yellowish green crystals; *ac*-tetramethyl-*pp'*-diaminodiphenylidene, $\text{CPh}_2 \cdot \text{C}(\text{CH} : \text{CH} \cdot \text{C}_6\text{H}_4 \cdot \text{NMe}_2)_2$.

m. p. 169–170°, yellowish-brown crystals; benzhydrylidenebenzocycloheptadiene, $\text{C}_6\text{H}_4 \cdot \left\langle \begin{smallmatrix} \text{CH} : \text{CH} \\ \text{CH} : \text{CH} \end{smallmatrix} \right\rangle \text{C} : \text{CPh}_2$, m. p. 92°, yellow crystals;

benzhydrylidenedimethylbenzocycloheptadiene, $\text{C}_6\text{H}_4 \cdot \left\langle \begin{smallmatrix} \text{CH} : \text{CH} \\ \text{CH} : \text{CH} \end{smallmatrix} \right\rangle \text{C} : \text{CPh}_2$, m. p. 92°, yellow crystals;

benzhydrylidenediphenylbenzocycloheptadiene, m. p. 181–182°.

p-dimethylaminoacetophenone, m. p. 105.5°, is obtained in small yield using dimethylaniline, acetic anhydride, and zinc chloride for four hours (the substance, m. p. 58°, described as *p*-dimethylaminoacetophenone in the literature is the monomethylated compound).

γ-Benzhydrylidene-pentamethylene oxide, $\text{O} \cdot \left\langle \begin{smallmatrix} \text{CH} : \text{CH} \\ \text{CH} : \text{CH} \end{smallmatrix} \right\rangle \text{C} : \text{CPh}_2$, m. p. 86°.

Camphrene itself, possesses very weak basic properties. Dimethylcamphor, $\text{C}_{10}\text{H}_{16} \cdot \left\langle \begin{smallmatrix} \text{C} : \text{CH} \cdot \text{NMe}_2 \\ \text{CO} \end{smallmatrix} \right\rangle$, m. p. 63–64°, is prepared by treating a well-cooled, methyl-alcoholic solution of oxycamphor with the calculated amount of alcoholic dimethylamine.

C. S.

Diastereoisomeric Chloroimino-ketones. PETER P. PETERSON *Am. Chem. J.*, 1911, 46, 325–344.—In a preliminary paper, Peter and Peterson (Abstr., 1910, i, 323) have described the α - and β -isomides of *p*-chlorobenzophenone. A full account of the work is given, together with a description of the α - and β -chloroimides, *acetoxybenzophenone* and *pp*-chloromethoxybenzophenone.

Chloroimino benzophenone, $\text{C}_6\text{H}_4\cdot\text{NCl}$, m. p. 37° , prepared by the action of hypochlorous acid on imino benzophenone, forms thin crystals.

α -*Chloroimino-p-methoxy benzophenone*, $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CPh}\cdot\text{NCl}$, m. p. 54° , crystallises in thin plates; the β -compound, m. p. 54° , forms asymmetric crystals. The two forms were proved to be identical by treating them with dry hydrogen chloride, then heating them both into chloroimino-*p*-methoxy benzophenone, which is decomposed by water into ammonium chloride and benzophenone.

p-*Chloro-p-methoxy benzophenone*, $\text{C}_6\text{H}_4\text{Cl}\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$, m. p. 65° , was prepared by the action of anisole on *p*-chlorobenzoyl chloride in the presence of aluminium chloride. α -*Chloroimino-p-chloro-p-methoxy benzophenone*, $\text{ClC}_6\text{H}_4\cdot\text{C}(\text{NCl})\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$, m. p. 94° , forms thin plates; the β -compound, m. p. 65° , large crystals; their structural identity was proved in the same way as in the previous case.

o-*Chloro-p-methoxy benzophenone*, $\text{C}_6\text{H}_4\text{Cl}\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$, m. p. 250° , prepared from *o*-chlorobenzoyl chloride and anisole, has b. p. $250^\circ/30\text{ mm.}$

δ -Phenylbutyl Ketones and δ -Phenylvaleric Acid. W. BORSCHKE (*Ber.*, 1911, 44, 2594—2596).—The unsaturated condensation products of cinnamaldehyde and ketones obtained by the action of hydrogen and colloidal palladium to the corresponding saturated substances, thus yielding a series of ketones containing the group $\text{CH}_2\text{Ph}\cdot(\text{CH}_2)_3\cdot\text{CO}$, and therefore designated δ -phenylbutyl ketones. The simplest member, δ -phenylbutyl methyl ketone, $\text{CH}_2\text{Ph}\cdot(\text{CH}_2)_3\cdot\text{CO}\cdot\text{Me}$, prepared from cinnamylideneacetone in cold methyl alcohol, is a refractive liquid, b. p. $268^\circ\text{--}269^\circ$, with a characteristic sweet odour; its oxime has b. p. $179^\circ\text{--}180^\circ/12\text{ mm.}$ When shaken with a solution of bromine in 5% sodium hydroxide at 0° , the ketone yields δ -phenylvaleric acid, m. p. 61° , in 35% yield, and the sodium salt, b. p. $173^\circ/35\text{ mm.}$, of the acid.

β -Keto- $\alpha\alpha$ -dialkyl Alcohols. III. EDMOND E. BROSART and HERMAN (*Ann. Chim. Phys.*, 1911, [viii], 23, 522—544).—A continuation of the work described in the previous paper (Abstr., 1910, i, 534).—A continuation of the work described in the previous paper (loc. cit.), the investigation being now extended to ketones containing a phenyl group.

Phenyl acetoxy-tert.-butyl ketone, $\text{OAc}\cdot\text{CH}_2\cdot\text{CMe}_2\cdot\text{CPh}$, m. p. $155.5^\circ\text{--}156.5^\circ/11\text{ mm.}$, prepared by the general method (Abstr., 1910, i, 248), furnishes a *p*-nitrophenylhydrazone, m. p. 125° , crystallising in long, orange-yellow needles from alcohol, and on hydrolysis with a 10% solution of potassium hydroxide in water yields phenyl isopropyl-tert.-butyl ketone, b. p. $152^\circ\text{--}153^\circ/12\text{ mm.}$ The latter ketone yields an oxime, m. p. 122.5° , crystallising in slender needles, a *p*-nitrophenylhydrazone, m. p. 157° , forming yellow needles, and a phenylhydrazone, m. p. 89° , crystallising in long needles from benzene on addition of light petroleum. Both phenyl hydroxy-tert.-butyl ketone and its derivative give on hydrolysis by warm alkalis phenyl isopropyl-

formaldehyde. On dehydration by phosphoric oxide, phenyl isobutyl ketone might be expected to yield tiglylbenzene or dimethylacrylbenzene, but the substance actually produced in this reaction appears to be benzoylmethylcyclopropane, $\text{COPh} \cdot \text{CMe} \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix}$.

117—119°. This gives a *p*-nitrophenylhydrazone, m. p. 175°, as crystalline, yellow powder. Tiglylbenzene (phenyl α -methylpropenyl ketone, $\text{COPh} \cdot \text{CMe} \cdot \text{CHMe}$, b. p. 117.5°/10 mm., obtained by condensing tiglyl chloride with zinc phenyl bromide, yields a *p*-nitrophenylhydrazone, m. p. 136°, crystallising in long, yellowish-red needles. Dimethylacrylbenzene [phenyl isobutenyl ketone], $\text{COPh} \cdot \text{CH} \cdot \text{CHMe}_2$,

b. p. 117.10 mm., similarly prepared, gives a *p*-nitrophenylhydrazone, m. p. 132°, which crystallises from warm alcohol.

Acetoxy- β -phenylpivalyl chloride, $\text{OAc} \cdot \text{CHPh} \cdot \text{CMe}_2 \cdot \text{COCl}$, b. p. 160 mm., m. p. 41°, is readily converted into the corresponding pivalate, m. p. 191—193°. With zinc ethyl iodide, it condenses to acetoxy- β -acetoxy- β -phenyltert.-butyl ketone, $\text{OAc} \cdot \text{CHPh} \cdot \text{CMe}_2 \cdot \text{COEt}$, b. p. 160—165 mm., m. p. 42°, with some acetoxyphenylpivalyl chloride and isobutonylbenzene (nitrosite, m. p. 154°). From the mixture of these products the corresponding keto-alcohol could not be separated, since in contact with alkalis the acetoxy-compound readily decomposed into benzaldehyde and ethyl isopropyl ketone. As the keto-alcohol could not be isolated, its dehydration could not be studied. It should furnish dimethylatropylethane, $\text{CMe}_2 \cdot \text{CPh} \cdot \text{COEt}$, b. p. 124°/mm., which was prepared by condensing dimethylatropyl chloride, b. p. 120.5°/11 mm. (*p*-toluidide, m. p. 135—136°, slender needles), with zinc ethyl iodide. It furnishes a *p*-nitrophenylhydrazone, m. p. 158°, crystallising in yellowish-red needles from alcohol. T. A. II.

The Nature of the Carbon Double Linking. III. The Semides of Anisylidenecinnamylidenecetone. HUGO BAUER and HERMIG DIETHELM (*Ber.*, 1911, 44, 2691—2697).—Anisylidenecinnamylidenecetone (*p*-methoxystyryl β -styrylvinyl ketone),

may be prepared by condensing *p*-methoxystyryl methyl ketone with formaldehyde by means of potassium hydroxide in alcoholic solution (compare Scholtz and Einhorn, *Abstr.*, 1896, i, 368). When treated with bromine in glacial acetic acid solution, it yields a dibromide,

a dibromide,

crystallising in small, colourless needles, m. p. 139—140° and 136° respectively. The bromine atom adjacent to the anisyl group in these compounds is very mobile, and is readily replaced by other groups.

p-Bromo- η -methoxy- α -phenyl- η -*p*-anisyl- Δ^7 -heptadien- ϵ -one,

prepared by boiling the dibromide with methyl alcohol, crystallises in yellow plates, and gives a deep bluish-violet coloration with strong sulphuric acid; the corresponding ethoxy-compound is an oil.

ζ-Bromo-η-acetoxy-α-phenyl-η-p-anisyl-Δ⁷-heptadien-ε-one,

$\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}\cdot\text{CHBr}\cdot\text{CH}(\text{OAc})\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$,
obtained by the action of magnesium acetate on the dibromide in an
alcoholic solution, crystallises in stout, pale yellow prisms, m. p. 174—175°.

γδ-Tribromo-η-methoxy-α-phenyl-η-p-anisyl-Δ⁷-hepten-ε-one,

$\text{CHPh}\cdot\text{CH}\cdot[\text{CHBr}]_2\cdot\text{CO}\cdot\text{CHBr}\cdot\text{CH}(\text{OMe})\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$,
prepared either by boiling *p*-methoxystyryl β-styrylvinyl ketone
tetrabromide with methyl alcohol or by the addition of bromine to
the preceding bromomethoxy-compound in glacial acetic acid solution,
crystallises in slender, white needles, m. p. 176—177·5°. When treated
with pyridine, it loses hydrogen bromide, yielding γδ-dibromo-η-methoxy-
α-phenyl-η-p-anisyl-Δ⁷-heptadien-ε-one,

which forms yellowish-brown leaflets, m. p. 174—175°.

That the addition of bromine to *p*-methoxystyryl β-styrylvinyl ketone
takes place at the double linking adjacent to the anisyl group was
proved by the oxidation of the above-mentioned ζ-bromo-η-methoxy-
phenylanisylheptadienone by means of potassium permanganate in
acetone solution to anisaldehyde and αβ-dihydroxy-γ-phenyl-γ-butenol
lactone (Fischer and Stewart, Abstr., 1892, 1447). F. E.

Acylated Phenanthrenes and Some of their Derivatives

CONRAD WILLGERODT and BRUNO ALBERT (*J. pr. Chem.*, 1911, p. 86, 383—394).—9-Acetylphenanthrene, $\text{C}_{16}\text{H}_{10}\text{O}$, prepared by the
action of acetyl chloride and phenanthrene in carbon disulphide
solution in the presence of aluminium chloride, crystallises in leaflets,
m. p. 123°, having a bluish fluorescence; it yields an oxime, crystallising
in leaflets, m. p. 86°, and a phenylhydrazone, light yellow leaflets,
m. p. 181°. When oxidised with five to six times its weight of
chromium trioxide in glacial acetic acid solution, the ketone gives
the ordinary form of phenanthraquinone, crystallising in needles,
m. p. 205°. Oxidation with twice its weight of chromium trioxide
results in the formation of a second modification, which crystallises as
lustrous, golden leaflets, m. p. 204—205°, and is converted by heating
in cold concentrated sulphuric acid or by prolonged heating in an
alcoholic potassium hydroxide into the ordinary form; the same trans-
formation takes place when the leaflets are heated at 180—200°. Both
forms yield with *o*-phenylenediamine the same phenanthraquinone
azine, m. p. 219—220°. When heated with yellow ammonium
sulphide at 170—180°, acetylphenanthrene yields 9-phenanthryl-
acetamide, $\text{C}_{16}\text{H}_{13}\text{ON}$, crystallising in white leaflets, m. p. 250—251°,
together with 9-phenanthrylacetic acid, $\text{C}_{14}\text{H}_9\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, which crys-
tallises in small needles, m. p. 213—215°, and forms a yellow, gelatinous
silver salt.

9-aa-Dichloroethylphenanthrene, $\text{C}_{14}\text{H}_9\cdot\text{CMeCl}_2$, prepared from
9-acetylphenanthrene and phosphorus pentachloride, crystallises as
small, yellow needles, which decompose at 80—100° without melting.

Acetylphenanthrene is reduced by zinc and glacial acetic acid to
9-phenanthrylmethylcarbinol (Pechor, Abstr., 1906, i, 820), and by
hydriodic acid and phosphorus to 9-ethylphenanthrene, $\text{C}_{16}\text{H}_{14}$, which
forms lustrous needles, m. p. 61°.

The interaction of phenanthrene and excess of acetyl chloride in the presence of aluminium chloride yields 9:10-diacetylphenanthrene, $\text{C}_{14}(\text{OMe})_2$, which crystallises in white needles, m. p. 178°, having a green fluorescence, and forms a phenylhydrazone, m. p. 189°, a biophenyl-diazine, $\text{C}_{14}\text{H}_8(\text{CMe:N:NHPb})_2$, small, yellow needles, m. p. 238°, and a diazime, leaflets, m. p. 258—260°. When oxidised with chromium trioxide in glacial acetic acid solution, the diacetyl derivative is converted into phenanthrene-9:10-diketodicarboxylic anhydride.

It forms a light yellow powder, m. p. above 360°, and yields a yellow silver salt, $\text{C}_{14}\text{H}_6(\text{CO} \cdot \text{CO}_2\text{Ag})_2$.

By methods similar to those described in the case of the monoacetyl derivative, 9:10-diacetylphenanthrene has been converted into 9:10-diacetyl-10-ethylphenanthrene, $\text{C}_{14}\text{H}_8(\text{CHMe} \cdot \text{OH})_2$, crystallising in leaflets, m. p. 165—166°, 9:10-di-*aa*-dichloroethylphenanthrene, $\text{C}_{14}\text{H}_8(\text{CMcCl}_2)_2$,

which forms yellow leaflets, decomposing at 130—140° without melting, and 9:10-diethylphenanthrene, which crystallises in large, lustrous leaflets, m. p. 90—91°.

9-Benzoylphenanthrene, $\text{C}_{14}\text{H}_9 \cdot \text{COPh}$, forms lustrous, white needles, m. p. 127°, and yields 9-benzylphenanthrene, crystallising in large, white leaflets, m. p. 91—92°, when distilled with zinc dust in a stream of hydrogen.

9:10-Dibenzoylphenanthrene forms leaflets, m. p. 317°; it is reduced with phosphorus and hydriodic acid at 180—190° to 9:10-dibenzylphenanthrene, which crystallises in needles, m. p. 180—182°. F. B.

The Two Forms of *o*-Benzoquinone. FRIEDRICH KEHRMANN (*Ber.*, 1911, 44, 2632—2633).—The author is of opinion that the question, whether the two modifications of *o*-benzoquinone are isomeric and desmotropic, has not been answered; especially, a certain proof has not been given that the colourless form has the peroxide formula and the coloured form the diketo-formula. The colourless form has not been analysed, and might well be a hydrated *o*-benzoquinone, $\text{O}(\text{H})_2(\text{OH})_2$, or even an additive compound containing ether (compare Willstätter and Müller, this vol. i, 728). C. S.

Action of Magnesium Methyl Iodide on *p*-Xyloquinone and Folioquinone. EUGEN HAMBERGER and LOUIS BLANGEY (*Annalen*, 1911, 384, 272—322).—The action of magnesium methyl iodide on *p*-xyloquinone has been examined very thoroughly, and on folioquinone more superficially. In the former reaction the product obtained after the usual operations consists of unchanged material, amorphous substances, about 25% of *p*-xyloquinol, ψ -cumoquinol 1:2:5-trimethylquinol, ψ -cumenol, 2:2:5-trimethyl-2:3-dihydro-*p*-benzoquinone, $\text{CO} < \begin{array}{c} \text{CMc}_2 \cdot \text{CH}_2 \\ \text{CH} = \text{CMe} \end{array} > \text{CO}$, and smaller amounts of prehnitol, trimethylcyclohexandione, and di-*p*-xyloquinol monomethyl ether, together with resinous and oily substances.

2:2:5-Trimethyl-2:3-dihydro-*p*-benzoquinone, [1:1:4-trimethyl-

Δ^8 cyclohexene-2:5-dione] m. p. 86°, crystallises in large, highly refractive, yellow prisms, has an odour of camphor, is extremely volatile with steam, and forms a *p*-nitrophenylhydrazone, $C_{15}H_{11}O_5N_2$ (two forms, one having m. p. 244.5—245.5°, the other decomposing at 306—308°), and a *bis*-semicarbazone, $C_{11}H_{13}O_4N_6$, blackening at 400°. *Tetramethylcyclohexanone*, which may have the constitution

(the former being the more probable), forms colourless prisms, m. p. 110—111°, has an odour of borneol and peppermint, is extremely volatile with steam, and forms a *bis*-semicarbazone, $C_{11}H_{13}O_4N_6$, m. p. 330° (decomp.). *Di-p-xyloquinol monomethyl ether*,

m. p. 220—220.5°, colourless needles, forms an *acetyl* derivative $C_{19}H_{22}O_5$, m. p. 191—192°, *p*-nitrophenylhydrazone, $C_{23}H_{20}O_5N_2$, m. p. 272—272.5°, and a *semicarbazone*, $C_{15}H_{22}O_4N_2$, m. p. 272—273°.

3:4-Xyloquinol, toluhydroquinone, *p*-xylohydroquinone, and *p*-xyloquinol have been isolated from the product obtained from toluquinone and magnesium methyl iodide.

An examination of the constitutions of the preceding substances shows that in *p*-xyloquinone and toluquinone, which contain a system $\overset{1}{\text{O}}\text{C}\overset{2}{\text{C}}\overset{3}{\text{C}}\overset{4}{\text{C}}\overset{5}{\text{C}}\overset{6}{\text{O}}$, the addition of the magnesium methyl iodide occurs in the 1:2- or the 1:4-, but not in the 1:6-, position (comp. Kohler, Abstr., 1905, i, 358). Consequently, the authors believe that during the reduction of quinones to hydroquinones the addition of hydrogen does not take place directly at the oxygen atoms of the quinone, but in the 1:2- and 1:4-positions (above scheme), the hydroquinone being produced subsequently by intramolecular change.

[Preparation of Anthraquinone Derivatives.] FABRIK RIKEN VORM. FRIEDR. BAYER & CO. (D.R.-P. 234518).—When halogenated aromatic sulphones are boiled with α -aminoanthraquinone in a suitable solvent (such as nitrobenzene or naphthalene) in the presence of a condensing agent (copper acetate), compounds of valuable tinctorial properties are formed.

The product from α -aminoanthraquinone (1 mol.) and *pp*-dinitrophenylsulphide forms brownish-red crystals, whilst the compound with 4-amino-1-benzylaminoanthraquinone and the foregoing sulphide furnishes a compound, violet crystals, which in the vat dye-works gives a very fast violet colour.

The tinctorial properties of these and other compounds of a similar nature are tabulated in the original. F. M. G. M.

Preparation of Aminoanthraquinones and of Amino naphthantraquinones or their Derivatives. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 234917).—Aminoanthraquinones and aminonaphthantraquinones may be prepared by heating halogenated

benzoic acids with ammonium hydroxide under pressure in the presence of a catalyst (such as copper), and submitting the amino-acids so obtained to the action of a dehydrating agent.

4.5-(*ortho*-2-*p*-toluoylbenzoic acid, m. p. 168—170° (prepared from toluene and 4-chlorophthalic anhydride), was heated at 190—195° for twelve hours with 20% ammonium hydroxide in the presence of copper powder, the solution just acidified, and then neutralised with sodium acetate, when the amino-acid separated as a greyish-brown powder.

2-Amino-6(7)-methylanthraquinone, orange-yellow needles, m. p. 6—257°, was obtained by heating the foregoing amino-acid at 200° for 10 parts of 90% sulphuric acid and subsequent crystallisation in xylene.

5.6-(*ortho*-2-*p*-toluoylbenzoic acid (prepared from toluene and chlorophthalic anhydride) yielded an amino-acid (pale grey powder), which was subsequently converted into 1-amino-6(7)-methylanthraquinone, red needles, m. p. 175°.

6. Chloro-2-*m*-xyloylbenzoic acid, m. p. 162°, obtained from phthalic anhydride and *o*-chloro-*m*-xylene, gave an amino-acid crystallising in yellow needles, m. p. 140° (decomp.), and subsequently furnished amino-2:4-dimethylanthraquinone, dark red crystals, m. p. 293°.

5.5-(*ortho*-2-naphthoylbenzoic acid, m. p. 175° (prepared from naphthalene and 4-chlorophthalic anhydride), yielded a grey amino-acid, which was converted into an aminonaphthanthraquinone, shining, red needles, m. p. 238°.

Chloro-2-naphthoylbenzoic acid, m. p. 217—220°, obtained from phthalic anhydride and 2-chloronaphthalene, gave an amino-acid (dark yellow powder), and finally an aminonaphthanthraquinone, bluish-violet, glistening needles, m. p. 182°. F. M. G. M.

Preparation of Condensation Products in the Anthracene Series. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 234977).—

Anthraquinone-1:5-bisanthranilic acid, a dark violet powder, is prepared by heating potassium anthranilate in nitrobenzene solution with 1:5-dichloroanthraquinone in the presence of a condensing agent; when this is heated at 100° with concentrated sulphuric acid, it furnishes a condensation product in the form of a blue powder.

Anthraquinone-1:5-bis-*o*-thiolbenzoic acid, an orange-red powder, obtained in a similar manner from 1:5-dichloroanthraquinone and potassium *o*-thiolbenzoate in alcoholic solution, yields when heated at higher temperature with sulphuric acid (23% anhydride) a product which forms a red powder. These compounds have probably the

substitution: $C_6H_4 \begin{smallmatrix} \diagup X \diagdown \\ \diagdown CO \diagup \end{smallmatrix} C_6H_2 \begin{smallmatrix} \diagup CO \diagdown \\ \diagdown CO \diagup \end{smallmatrix} C_6H_4 \begin{smallmatrix} \diagup X \diagdown \\ \diagdown CO \diagup \end{smallmatrix} C_6H_4$, where X is either sulphur or an imino-group. F. M. G. M.

Preparation of Anthraquinone Condensation Products. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 234922).—When 2-aminoanthraquinone is boiled (in nitrobenzene solution) with trichloro-

methyl mercaptan in the presence of a condensing reagent (e.g. copper), *s*-dianthraquinonylthiocarbamide,

is obtained in the form of a red powder.

The tinctorial properties of this and similar compounds, obtained from 1:4-diaminoanthraquinone, $\alpha\beta$ -diaminoanthraquinone, *p*-aminanthraquinone, 1-aminoanthraquinone, 1:4-aminoanthraquinone, and 1:5-diaminoanthraquinone respectively are tabulated in the original.

F. M. G. M.

Chrysophanic Acid, Frangula-Emodin, and Some Oxonium Compounds of Anthracene Derivatives. OTTO FISCHER and HANS GROSS (*J. pr. Chem.*, 1911, [ii], 84, 369—382).—Chrysophanic acid may be obtained from chrysarobin by oxidation with chromic acid and demethylation of the resulting product by heating with hydrochloric acid in acetic acid solution. The mixture of chrysophanic acid and emodin thus obtained is separated by means of aqueous sodium carbonate. Successive treatment of the mixture with potassium hydroxide and methyl sulphate yields emodin trimethyl ether and chrysophanic acid dimethyl ether.

The transformation of diacetylchrysophanic acid into diacetylresorcinol is best accomplished by oxidation with chromic acid at 50—60° in a solution of equal parts of acetic anhydride and glacial acetic acid.

Dibenzoylchrysophanic acid, prepared by heating chrysophanic acid with benzoyl chloride in the presence of pyridine, crystallises in slender needles, m. p. 212° (compare de la Rue and Müller, this Journ., 1857, 10, 298). It is converted by oxidation with chromic acid into *dibenzoylrhein*, which crystallises in stellar aggregates of yellow prisms, m. p. 253—255°, and gives a red coloration with concentrated sulphuric acid.

When heated with concentrated ammonia, chrysophanic acid yields a compound, $\text{C}_{15}\text{H}_{11}\text{O}_3\text{N}$, crystallising in slender needles of a bronze lustre. The compound has the character of an amide, dissolves in alkalis and ammonia, forming reddish-violet solutions, and gives an orange coloration with sulphuric acid; the ammonium salt is unstable.

Triacetylemodin, prepared from frangula-emodin by heating with acetic anhydride and sodium acetate, has m. p. 196—197° (Liebermann gives 190°). It is oxidised by chromic acid to *triacetylemodic acid*, $\text{C}_{21}\text{H}_{14}\text{O}_{10}$, which crystallises in slender, yellow needles, and is hydrolysed by aqueous potassium hydroxide to *emodic acid*, $\text{C}_{15}\text{H}_8\text{O}_6$. The latter compound crystallises in orange-yellow needles, which decompose at 340—360°, and dissolve in alkalis with a reddish-violet coloration; it has the constitution of a trihydroxy- β -anthraquinonecarboxylic acid.

[With P. NEBER.]—A large number of anthracene derivatives have been studied with respect to their ability to form oxonium salts. Whilst anthracene and its methyl and chloro-derivatives together with anthraquinone, the methylanthraquinones, dimethyldihydroanthra-

frangulae, and diethylidihydroanthraquinone do not yield oxonium salts with perchloric and hydrobromic acids, and the hydroxyanthraquinones give at most yellowish-red or red solutions, the alkyloxy-derivatives of anthraquinone often yield stable salts. From this the conclusion is drawn that the presence both of carbonyl and alkyloxy-groups is essential for the formation of stable oxonium salts in the anthracene series.

The following salts, all of which are red in colour, were isolated: the hydrobromide, $C_{18}H_{17}O_2Br$, the zincbromide, $C_{18}H_{17}O_2Br_2Zn$, and the perchlorate, $C_{18}H_{17}O_2Cl$, of emodin trimethyl ether; the hydrobromide and zincbromide, $C_{17}H_{15}O_4Br_2Zn$, of chrysophanic acid dimethyl ether, and the hydrobromide and zincbromide of dimethylchrysazin (1:8-dimethoxyanthraquinone). The hydrochlorides and zincchlorides may also be isolated, but these are more unstable than the corresponding bromides. The salts of 1:2-, 1:4-, 1:5-, and 1:6-dimethoxyanthraquinone and of rufigallol hexamethyl ether with perchloric or hydrobromic acid are too unstable to be isolated.

Rufigallol hexamethyl ether, $C_{20}H_{20}O_8$, prepared by the action of methyl sulphate on its potassium salt in the presence of anhydrous potassium carbonate, crystallises in light yellow needles, m. p. 240° .

F. B.

Relationship between Chrysophanic Acid, Aloe-Emodin, and Rhein. OTTO A. OESTERLE (*Arch. Pharm.*, 1911, 249, 445—449).

It is now shown that on reduction aloe-emodin furnishes chrysophanhydranthrone, and this on oxidation by air in presence of sodium hydroxide solution furnishes chrysophanic acid. This observation in conjunction with those recorded already (Abstr., 1903, i, 356; 1908, i, 905; 1909, i, 946, and following abstract; Léger, Abstr., 1902, i, 549; Frobenius and Hepp, Abstr., 1907, i, 428; Robinson and Simonsen, Trans., 1909, 96, 1085; Fischer, Falco, and Gross, Abstr., 1911, i, 309, and Tutin and Clower, Trans., 1911, 99, 946) indicates that rhein, aloe-emodin, and chrysophanic acid are 1:8-dihydroxyanthraquinones containing respectively a $-COOH$, $-CH_2OH$, and $-CH_3$ group in position 2.

T. A. H.

Constitution of Frangula-Emodin. OTTO A. OESTERLE and W. SYPKENS-TOXOPÉUS (*Arch. Pharm.*, 1911, 249, 311—321).—The previous formulation of emodin as 3:6:7-trihydroxy-2-methylanthraquinone (Oesterle and Tisza, Abstr., 1908, i, 350) is of doubtful validity in view of Oesterle and Johann's observation (Abstr., 1910, i, 860) that methyl sulphate methylates both hydroxyl groups of chrysophanic acid, although one is probably in the α - and the other probably in the β -position. The results of investigations of the action of ethyl chloroacetate on emodin, and of aniline on tetranitro-emodin, indicate that two hydroxyls are in the α -position and one in the β -position, whence emodin is either 1:6:8-trihydroxy-2-methylanthraquinone or 1:5:7-trihydroxy-2-methylanthraquinone.

Emodin reacts with ethyl chloroacetate to form chiefly *ethyl*

emodindiglycollate diacetate, $C_{31}H_{32}O_8Me(OAc)_2 \cdot O-CH_2 \cdot CO_2Et$, m. p. 192—193°, which crystallises from alcohol on addition of chloroform, and when heated with potassium hydroxide in alcohol furnishes *potassium emodindiglycollate*, crystallising in red needles. A small amount of *ethyl emodindiglycollate acetate*,

$C_{31}H_{32}O_8Me(O-CH_2 \cdot CO_2Et)_2 \cdot OAc$, m. p. 152°, crystallising from 95% alcohol in bright yellow, slender needles, or from dry alcohol in thick needles, is formed. On hydrolysis this furnishes a product, m. p. 252—253° (decomp.), crystallising from pyridine on addition of alcohol.

Tetranitro-emodin, obtained by nitration of emodin with nitric acid (D 1486—1500), crystallises from acetic acid in orange-yellow needles and explodes when heated. When boiled with aniline during two hours, it furnished bluish-violet flocks of a substance, which agreed in ultimate composition with that required by the formula

that is, tetranitro-emodin in which two nitro-groups have reacted with aniline and the three hydroxyl groups have been replaced by aniline residues (D.R.P. 89080). This substitution of hydroxyl groups by aniline residues takes place most readily when the hydroxyl groups occupy para-positions with respect to nitro-groups in hydroxy-anthraquinones (*loc. cit.*)

T. A. H.

Existence of Quinonoid Properties in Anthraquinone Derivatives. ROLAND SCHOLL [with G. VON WOŁODKOWITSCH], *Ber.* 1911, 44, 2370—2377. Compare Bally and Scholl, this vol., i, 678. 1:2-Benzanthraquinone when nitrated with a mixture of nitric and acetic acids and acetic anhydride yields a mixture of two yellow mono-

nitro-derivatives, $C_{18}H_9O_2N$, m. p. 277—278°, and 250—251°. On reduction of the less fusible isomeride with phenylhydrazine, the corresponding amine, $C_{18}H_{11}O_2N$, is not obtained, water being eliminated between the amino- and carbonyl group, and the anhydro-compound further reduced to *O,N'*-dihydro-2:9-indoloanthrone (formula I), $C_{18}H_{11}ON$, a green substance. When dissolved in sodium hydroxide this compound is oxidised by the air to a brown substance, 2:9-indoloanthrone (formula II).

This compound, in contrast to anthraquinone itself and its derivatives, exhibits marked quinonoid properties. It reacts energetically with phenylhydrazine, being reduced to the dihydro compound (formula I above). It acts at the ordinary temperature in benzene or ethereal solution as an oxidising agent towards hydrogen iodide and sulphurous acid, colours hæmatoxylin red, but does not blue guaiacum resin. These pronounced quinonoid properties are considered to be due to the influence of the pyrrole nucleus attached to another nucleus of entirely different character, and so causing the existence of a carbon-nitrogen double bond of a highly unsaturated nature. This

(I.)

(II.)

induces the conversion of a neighbouring benzenoid linking into an ethenoid, and brings out the quinonoid properties of the anthraquinone.

The more fusible isomeric nitro-1:2-benzanthraquinone is converted on reduction into a red amino-1:2-benzanthraquinone, m. p. 215° , which, since it does not give a vat dye when fused with potassium hydroxide or heated with antimony pentachloride in nitrobenzene solution, is considered to have the amino-group in the benzene nucleus. The nitro-derivative accordingly has formula III.

3-Methyl-1:2-benzanthraquinone when nitrated yields only one mononitroderivative; this must have the formula IV, since it is converted on reduction into a 3-methyl-2:9-indoloanthrone (V), which possesses typical quinonoid properties. An isomeric 4-nitro-derivative could not be obtained, owing to the steric hindrance of the methyl group occupying the α -position in the naphthalene nucleus.

1-Nitro-1:2-benzanthraquinone forms yellow plates or prisms, m. p. $277-278^{\circ}$. The isomeric 4-nitro-1:2-benzanthraquinone crystallises in slender needles, m. p. $250-251^{\circ}$. Both isomerides dissolve in concentrated sulphuric acid with an orange-red coloration.

4-Amino-1:2-benzanthraquinone forms red crystals, m. p. 215° , and dissolves in concentrated sulphuric acid with a reddish-brown coloration.

O,N-Dihydro-2:9-indoloanthrone is a green powder, but forms brown or brownish-red solutions with a green fluorescence.

2:9-Indoloanthrone is obtained in violet-brown flakes, which sinter at 160° , but do not melt. E. F. A.

2:8- or amphi-Chrysoquinone. ERICH BESCHKE [with FRANZ DREUM] (*Annalen*, 1911, 384, 173-192. Compare this vol., i, 873). --2:8- or amphi-Chrysoquinone, $C_{18}H_{10}O_2$, m. p. $288-290^{\circ}$ (decomp.), obtained by the action of lead dioxide on a suspension of 2:8-dihydroxychrysene in boiling acetic acid, crystallises in reddish-yellow needles, is odourless and non-volatile with steam, reacts instantly with phenylhydrazine or acidified potassium iodide, and forms a yellow, crystalline compound, $C_{18}H_{10}O_2 \cdot NaHSO_3 \cdot 2H_2O$, with sodium hydrogen sulphite. Its suspension in hot alcohol reacts in the presence of atmospheric oxygen with dilute sodium hydroxide to form, after acidification, 8-hydroxy-1:2-chrysoquinone, $OH \cdot C_{18}H_9O_2$, dark red needles, decomp. above 300° , and with aniline or ethylaniline to form 8-hydroxy-1:2-chrysoquinone-1-anil, $OH \cdot C_{18}H_9O \cdot NPh$, bluish-violet crystals, m. p. 230° (decomp. at 220°). The constitutions given to the two preceding substances are based on Willstätter and Parnas' experiences of the oxidising power of quinones of different types (*Abstr.*, 1907, i, 1056), and are supported by the following evidence.

The chief proof is the fact that aniline or ethylaniline, reacting with 2:8-chrysoquinone, produces the same anil. 8-Hydroxy-1:2-chrysoquinone, which is also easily obtained by the action of sodium hydroxide and air on a boiling alcoholic suspension of 2:8-diacetoxychrysene, forms a sodium salt, $C_{18}H_9O_2Na$, bluish-violet, almost black needles, is reduced by sodium hyposulphite to the colourless 1:2:8-trihydroxychrysene, and forms an acetyl derivative, m. p. 252°, red needles, ethyl ether, m. p. 246°, and benzoyl derivative, m. p. 232°. It does not appreciably react at the ordinary temperature with phenylhydrazine, acidified potassium iodide, or sulphurous acid. A hot saturated solution of the quinone in glacial acetic acid reacts with concentrated alcoholic *o*-phenylenediamine to form 8-hydroxy-1:2-chrysophenazine, $OH \cdot C_{18}H_8 \cdot \begin{smallmatrix} N \\ \diagup \diagdown \\ N \end{smallmatrix} > C_6H_4$, m. p. 292°, yellow needles, the

benzoyl derivative, m. p. 270°, acetyl derivative, m. p. 252°, and ethyl ether, m. p. 215°, of which are respectively identical with the corresponding substituted chrysophenazines obtained by condensing *o*-phenylenediamine with the corresponding derivatives of 8-hydroxy-1:2-chrysoquinone.

8-Hydroxy-1:2-chrysoquinone-1-anil yields 8-hydroxy-1:2-chrysoquinone by hydrolysis with mineral acids, and yields with acetic anhydride an acetyl derivative, $C_{20}H_{17}O_2N$, m. p. 215°, which is converted by dilute hydrochloric and a little acetic acid into 8-acetoxy-1:2-chrysoquinone.

1:2:8-Triacetoxychrysene, $C_{18}H_9(OAc)_3$, colourless crystals, m. p. 195°, is obtained by treating a solution of 8-acetoxy-1:2-chrysoquinone in boiling acetic anhydride with zinc dust. 1:2:8-Triethoxychrysene, $C_{18}H_9(OEt)_3$, colourless crystals, m. p. 142°, is prepared by treating an aqueous alcoholic suspension of the sodium salt of 8-hydroxychrysoquinone, with dilute sodium hydroxide and sodium hyposulphite, and subsequently with ethyl sulphate. It has been found that 2-hydroxy- α -naphthaquinoneanil is produced when β -naphthaquinone is boiled with ethylaniline in alcoholic solution. C.S.

Condensation of Menthones with Organomagnesium Compounds. Synthesis of Homologues of Menthol. MARCEL MURAT (*J. Pharm. Chim.*, 1911, [viii], 4, 294—299).—Magnesium phenyl bromide reacts with menthone to give 1-3-phenyl-1-methyl-4-isopropyl-3-cyclohexanol, $CH_2 \begin{smallmatrix} CHMe \cdot CH_2 \\ | \\ CH_2 \cdot CHPh \end{smallmatrix} > CPh \cdot OH$, b. p. 175°/20 mm., D_4^{20} 0.9262, n_D^{20} 1.527, $[\alpha]_D^{20}$ -16.32°. The racemic form prepared in the same way from thymomenthone had b. p. 170°/18 mm., D_4^{20} 0.9250. When treated with phenylcarbimide, or passed over alumina at 300°, dehydration occurs with production of the corresponding menthones. 3-phenyl-1-methyl-4-isopropylcyclohexene has b. p. 268—272°/760 mm., D_4^{20} 0.9700, n_D^{20} 1.537, $[\alpha]_D^{20}$ +13.9°.

Magnesium cyclohexyl bromide slowly acts on menthone, giving 3-cyclohexyl-1-methyl-4-isopropyl-3-cyclohexanol, monoclinic needles, m. p. 92°, together with 3-cyclohexyl-1-methyl-4-isopropylcyclohexene, b. p. 265°/760 mm., D_4^{20} 0.9897, n_D^{20} 1.498, $[\alpha]_D^{20}$ +6.2°.

Thymomenthone (inactive menthone) was prepared by passing the vapour of Brunel's thymomenthol (Abstr., 1906, i, 81) over copper at

it occurs as a viscous liquid, b. p. 212° , having a less pronounced odour than natural methone. When treated with magnesium cyclohexyl bromide, it yields *r*-cyclohexylthymonethal, b. p. $164^{\circ}/15$ mm. (decomp.), D_4^{20} 0.9931, n_D^{20} 1.529; the corresponding cyclohexylthymonethone has b. p. $260^{\circ}/756$ mm. W. O. W.

Terpenes and Ethereal Oils. CVII. Constitution and Synthesis of Pinolone and of Dihydropinolone (3-Acetyliso-propylcyclopentane). OTTO WALLACH (*Annalen*, 1911, 384, 153—208). Dihydropinolone, when prepared by the reduction of pinolone by Paal's method and purified through the semicarbazone, $C_{10}H_{18}ON_2$, m. p. 164 — 165° , is a colourless liquid with an odour of amyl acetate; it has b. p. 211° , D_4^{20} 0.8885, and n_D^{20} 1.4466. Its

recognition as 3-acetyliso-propylcyclopentane, $CH_3Ac \begin{smallmatrix} CH_2 \cdot CH_2 \\ | \\ CH_2 \cdot CHPr^s \end{smallmatrix}$, has been accomplished by its degradation to isopropylcyclopentan-3-one, and by its synthesis from this substance. Its degradation is represented essentially by the scheme: dihydropinolone \xrightarrow{NaOBr} $>CH \cdot CO_2H$ (b. p. 153 — $156^{\circ}/16$ mm.) $\rightarrow >CH \cdot CO \cdot NH_2$ (m. p. 164 — 165° ; identical with Seumler's dihydrocamphocenamides *b* [*Abstr.*, 1906, i, 681]) $\xrightarrow{H_2SO_4, KOH}$ $>CH \cdot NH_2 \rightarrow >CH \cdot OH \xrightarrow{CrO_3}$ isopropylcyclopentan-3-one.

The synthesis has been accomplished as follows: The interaction of isopropylcyclopentan-3-one (prepared from tannacetophorone), zinc, and ethyl α -bromopropionate in benzene leads to the formation of an hydroxy-ester, which by successive boiling with acetic anhydride, hydrolysis by alcoholic potassium hydroxide, and acidification yields

an acid, $(CO_2H \cdot CMe \cdot C \begin{smallmatrix} CH_2 \cdot CH_2 \\ | \\ CH_2 \cdot CHPr^s \end{smallmatrix})_n$, the distillation of which in nitrogen produces a hydrocarbon, $C_{10}H_{18}$, b. p. 172 — 174° , D_4^{20} 0.809, n_D^{20} 1.4506. This hydrocarbon has assigned to it the constitution

$CHMe \cdot C \begin{smallmatrix} CH_2 \cdot CH_2 \\ | \\ CH_2 \cdot CHPr^s \end{smallmatrix}$, on account of its exalted molecular refraction

and its behaviour. It is practically identical with the hydrocarbon, $C_{10}H_{18}$, b. p. 171 — 174° , D_4^{20} 0.812, n_D^{20} 1.4515, obtained by heating isohydropinolol, $OH \cdot CHMe \cdot CH \begin{smallmatrix} CH_2 \cdot CH_2 \\ | \\ CH_2 \cdot CHPr^s \end{smallmatrix}$, b. p. 215 — 216° ,

D_4^{20} 0.820, n_D^{20} 1.4569 (prepared by the reduction of dihydropinolone), with zinc chloride. The synthetic hydrocarbon (from the isopropylcyclopentanone) forms a blue nitrosochloride, which by successive treatment with boiling acetic acid and sodium acetate and with sulphuric acid is converted into a ketone, $COMe \cdot C \begin{smallmatrix} CH \cdot CHPr^s \\ | \\ CH_2 \cdot CH_2 \end{smallmatrix}$, semicarbazone, m. p. 182 — 184° , isomeric with pinolone. This ketone yields dihydropinolone when reduced by Paal's method.

The series of transformations whereby pulegone dibromide is converted into pulegenic acid (*Abstr.*, 1903, i, 567) has suggested an explanation of the course followed by pinyl tribromide during its

conversion into pinolone. This explanation leads to the conclusion that pinolone may be either

In harmony with this, the author finds that pinolonesemicarbazone, m. p. 158°, can be separated by repeated crystallisation into two portions, the less fusible of which has m. p. 173°.

Degradation of Nerol and its Constitution. A. BLUMANN and Otto ZEITSCHKE (*Ber.*, 1911, 44, 2590,—2593).—When nerol or geraniol is oxidised by 1% potassium permanganate at 0° and the product is subsequently treated with dilute chromic and sulphuric acids, acetone, levulic acid, and oxalic acid are obtained, the amount of levulic acid being practically the same in each case. These results confirm the view that nerol and geraniol are stereoisomers (*Zeitschel, Abstr.*, 1906, i, 521).

Influence of Water on the Rotatory Power of Camphor Solutions. ENDRE VON KAZAY (*Pharm. Post*, 1911, 44, 495, 497).—The value of $[\alpha]_D$ for camphor in a number of organic solvents is about +43·6°, independent of the nature of the solvent. The addition of water to the alcoholic or acetic acid solution causes a very marked alteration in the rotation. When the proportion of water in the alcoholic solution containing about 12% of camphor is increased from 4% to 37%, the rotation diminishes from 8·3° to 7·1°. When in acetic acid solution containing about 10% of camphor, the proportion of water is gradually increased from zero to 32·3%, the rotation gradually diminishes from 8·3° to 6·0°. If the proportion of water in a solution is known, the percentage of camphor, p , can be calculated from the formula: $p = (100d)/(B\alpha' + b)$, where B is 0·1308 for acetic acid solutions, and 0·12822 for alcoholic solutions.

Effect of Molecular Symmetry on the Optical Activity and Relative Rotatory Power of Aromatic Position Isomerides. THOMAS P. HILDITCH (*Zeitsch. physikal. Chem.*, 1911, 77, 482—497. Compare *Trans.*, 1908, 93, 1618; 1909, 96, 1578).—A more detailed account of work already published (compare *Proc.*, 1910, 22, 111). The relative effects of ortho-, meta- and para-isomerides on the rotatory power is illustrated by the behaviour of compounds containing methyl, halogen, hydroxy-, methoxy-, nitro-, and amino-groups.

Sodium camphor-β-thiosulphonate, $\text{C}_{10}\text{H}_{15}\text{O}\cdot\text{SO}_2\cdot\text{SNa}$, is prepared by interaction of camphor-β-sulphonyl chloride and sodium sulphide in boiling alcohol. It occurs in soft, colourless, crystalline masses. The corresponding acid is an oily substance, and unstable. The silver salt forms a cream-coloured powder. The anhydride, $[(\text{C}_{10}\text{H}_{15}\text{O})\cdot\text{SO}_2]_2$, is obtained in almost theoretical yield by boiling equivalent amounts of the sulphonyl chloride and the sodium salt dissolved in carbon tetrachloride. It occurs in pale yellow needles, m. p. 144°.

Dicamphor-β-sulphonyl disulphide, $[(\text{C}_{10}\text{H}_{15}\text{O})\cdot\text{SO}_2]_2$, was obtained by the action of iodine, dissolved in potassium iodide solution, on

phenyl camphor- β -thiosulphonate, and also by acting on the latter with sulphur monochloride in cold carbon tetrachloride. It occurs in colourless needles, m. p. 130°.

The phenyl camphor- β -sulphonates were all prepared by a modification of the Schotten-Baumann method. *Catechol dicamphor- β -sulphonate*, $C_8H_8(SO_2 \cdot C_{10}H_{15}O)_2$, forms colourless or slightly red crystals, m. p. 124°; the corresponding *resorcinol* compound melts at 59–130°, and the *quinol* compound at 187° (slight decomp.).

Pyrogallol tricamphor- β -sulphonate, $C_8H_8(SO_2 \cdot C_{10}H_{15}O)_3$, occurs in soft, colourless needles, m. p. 148° (decomp.). The corresponding *hydroquinol* compound forms prismatic crystals, m. p. 104–106°.

G. S.

[Essential Oils.] SCHIMMEL & Co. (*Bericht*, October 1911, pp. 151–152).—*Artemisia biennis*, according to Rabak, yields 0.03% of a dark brownish-red, sweet-smelling oil, D^{20}_4 0.893, $[a]_D^{20} + 4.39^\circ$, n_D^{20} 1.5181, acid number 0, ester number 16, acetyl ester number 17.28, which dissolves in 4 vols. or more of 95% alcohol, and probably contains ethylchavicol. According to the same author, *Artemisia serrata* yields 3% of a reddish-brown, bitter oil, D^{20}_4 0.913, $a_D + 6.8^\circ$, n_D^{20} 1.4602, acid number 1.6, ester number 10.0, acetyl ester number 43, which dissolves in 0.5 or more vols. 80% alcohol, and probably contains thujone.

Eucalyptus crenulata (round bush) leaves yield 1.7% oil, D^{20}_4 0.9364, n_D^{20} 1.5222, n_D^{20} 1.48005, which dissolves in 2.5 or more vols. of 70% alcohol with separation of paraffin, is brownish-yellow in colour after removal of traces of copper by acid, has mint-like odour, possibly due to menthone, and contains very little diosphenol.

Mandarin oil pressed from unripe fruits in Valencia had D^{15}_4 0.8665, n_D^{20} 1.47900, acid number 0.2, ester number 17.3, was incompletely soluble in 90% alcohol, and was of dark olive-green colour.

Helichrysum angustifolium oil from Dalmatia had D^{15}_4 0.9005, n_D^{20} 1.48209, acid number 0.9, ester number 61.1, and dissolved in 9 or more vols. of 90% alcohol. It was of olive-green colour, and resembled camomile oil in odour.

The Jalpaiguri (Indian) lemon-grass oils referred to previously (*Abstr.*, 1910, i, 328) have now been found to be derived from *Cymbopogon pendulus*, Stapf.

Cayenne linalee oil, like the Mexican product, contains methylheptenol.

Dalmatian laurel-leaf oil has D^{15}_4 0.9268, $a_D - 14.36^\circ$, n_D^{20} 1.46813, acid number 0.5, ester number 29.9, acetyl ester number 68.6, and is soluble in 2.5 or more vols. of 70% alcohol.

Dalmatian myrtle oil has D^{15}_4 0.9254, $a_D + 13.20^\circ$, n_D^{20} 1.46694, acid number 1.0, ester number 134.8, acetyl ester number 186.7, and is soluble in 3.2 or more vols. of 70% alcohol.

French peppermint, cultivated in Dalmatia, gave oils which after rectification had the following range of constants, D^{15}_4 0.9094–0.9141, $a_D - 11.45^\circ$ to -18.12° , n_D^{20} 1.46041–1.46783, acid number 0–1.0, total menthol 39.6–54.1%, ester menthol 2.6–3.8% and were soluble in 2.8 to 3 vols. of 70% alcohol with slight opalescence. According to

Henderson (*Chem. & Drug.*, 1911, 79, 216), English peppermint grown on the banks of a river yielded only 0.1% oil, D 0.9046, n_D^{20} 1.4571, total menthol 59.2%, ester menthol 3.9%, whilst that grown in open fields on clay soil gave 0.409% oil, D 0.9065, n_D^{20} 1.4571, total menthol 61.35%, ester menthol 5.57%, and a third sample grown on sandy soil gave 0.19% oil, D 0.9046, n_D^{20} 1.4571, total menthol 58.46%, ester menthol 4.74%. Italian peppermint oil from Pancalieri had D 0.9046, n_D^{20} 1.4571 to 1.4581, was soluble in 2.9 vols. of 70% alcohol, and deposited solid matter on cooling (Bourdēt, *Bull. Soc. chim.*, 1911, 18, 372).

Sage oil distilled in Dalmatia in August from dry herb had the following normal constants, D¹⁵ 0.9165, n_D^{20} 1.45871, and number 1.0, ester number 9.3, whilst oil distilled from fresh herb in May had D¹⁵ 0.9111, n_D^{20} 1.45871, ester number 10.3, and was more soluble in alcohol than the August oil.

Origanum hirtum *a-albiflorum* herb grown in Dalmatia furnished origanum oil having the following range of constants, D¹⁵ 0.9022—0.9400, n_D^{20} 1.43994—1.50436, soluble in from 2.8 vols. of 70% alcohol to 1.5 vols. of 80% alcohol, and containing from 51 to 60% thymol.

Dalmatian spike oil had D¹⁵ 0.9022—0.9033, n_D^{20} 1.43994 to 1.4400, acid number 0.9, ester number 5.4—5.6, and was soluble in from 4 to 5 vols. of 60% alcohol. *Lavandula spica* herb from Spain yielded 1.9% of brownish-yellow oil, D¹⁵ 0.9100, n_D^{20} 1.46523, and number 3.7, ester number 7.0, and was soluble in 2 vols. of 70% alcohol, but became opalescent with more alcohol.

According to Jeancard and Satie (*Perf. and Essent. Oil Rec.*, 1911, 2, 79) a so-called sandalwood from Guiana yielded oil having the following range of constants, D¹⁵ 0.963 to 1.0122, n_D^{20} 1.4630 to 1.4650, saponification value 13 to 65, after acetylation 65 to 117, on distillation it gave the following fractions: below 155°/20 mm. 1.4 to 27.4%, 155—160°/20 mm. 59 to 80%, and above 160°/20 mm. 1.4 to 13.6%. The second fraction contained a new constituent, *isotropanol*, b. p. 158—159°/20 mm., D²³ 1.0378, n_D^{20} 1.4630, which dissolved in 17 vols. 70% alcohol, and was colourless, viscous, and of agreeable odour, this substance is probably a tertiary alcohol.

Star anise oil contains *d*- α -pinene, *d*- β -phellandrene, dipentene, and *l*-limonene in the lower boiling fractions; as well as a fraction, 163—168°, having a turpentine-like odour, but which is free from β -pinene and sabinene.

Strobilanthes lupulinus flower buds yield an oil, D 0.9648, n_D^{20} 1.4688, acid number 1.7, ester number 257 (*Perf. and Essent. Oil Rec.*, 1911, 2, 96), having a strong, pleasant odour recalling those of tarragon and lavender.

A "wormwood" oil from Dalmatia had D¹⁵ 0.9188, acid number 1.3, ester number 64.4, and dissolved in 1 vol. 80% alcohol; it differed in odour from true wormwood oil, and was probably derived from another species of *Artemisia*. Wisconsin "wormwood" oil had D²⁰ 0.9165, saponification number 150 (forty minutes), after acetylation 231.8 to 236.2, and was dark, with a mint-like odour. It contained much thujone, and on hydrolysis gave formic and salicylic acids.

Oil from *Gaultheria fragrantissima* of the Nilgiris, India, had D^{20}_D 1.1877, n_D^{20} 1.53485, ester number 364.8, was reddish-brown in colour and resembled winter green oil in odour.

Cananga oil from German East Africa distilled from fresh flowers had D^{20}_D 0.9366, n_D^{20} 1.791, n_D^{20} 1.48451, acid number 1.1, ester number 136.5 and was soluble, with opalescence in 8 or more vols. of 80% alcohol.

Artemisia coerulescens herb from Turin gave 0.24% oil, D^{20}_D 0.9179, n_D^{20} 1.559, acid number 11.3, ester number 42.0, which was brown and of buttery consistence, and had an odour recalling that of hyssop oil. The crystalline matter deposited by the oil melted at 108°.

Cardamom roots from Indo-China yielded 0.64% citron-yellow oil, D^{20}_D 0.9066, n_D^{20} 1.5257, n_D^{20} 1.48151, acid number 3.7, ester number 87.2, acetyl ester number 96.7, which was different from the seed oil in odour. It contained bisabolene, cineole, and paraffin.

Juniperus procera wood sawdust from German East Africa yielded 3.2% of oil, D^{20}_D 0.9876, n_D^{20} 1.50893, acid number 14.9, ester number 8.4, acetyl ester number 70. Fragments of the wood gave 3.2% of oil, which was semi-solid, and, after removal of solid matter, had D^{20}_D 1.0289, n_D^{20} 1.51011, acid number 27.06, ester number 7.93, acetyl ester number 82.6. The deposited crystals were cedar camphor.

Cinnamon *Burmanni* bark from Timor and the Celebes gave 0.5% oil, D^{20}_D 1.0198, n_D^{20} 1.50, n_D^{20} 1.58282, which was not so pleasant in aroma as Ceylon cinnamon bark oil, but contained 77% of aldehydes and 11% phenols.

Meriania benghalensis leaves from Erythraea gave 1.5% bright brown oil, D^{20}_D 0.9513, n_D^{20} 1.525, n_D^{20} 1.47490, acid number 3.7, ester number 14.8, which had an odour resembling those of rosemary and sage. It deposited *d*-camphor when cooled.

Antolina chamaecyparissus herb from Turin gave 0.47% dark brown oil, D^{20}_D 0.9065, n_D^{20} 1.50040, acid number 6.6, ester number 16.4, acetyl ester number 74.2, with an odour resembling that of wormwood oil.

Satureja cuneifolia oils from Dalmatia had the following range of constants, D^{20}_D 0.9182 to 0.9440, n_D^{20} 1.50 to 1.515, n_D^{20} 1.49816 to 1.50556, and contained from 28 to 59% of phenols, chiefly carvacrol, whilst the non-phenolic portion had a strong odour of eymeno.

A résumé of literature published since April, 1911, on the analysis, physical properties, chemistry, etc., of essential oils and their constituents is also given. T. A. H.

[Essential Oils.] ROURE-BERTRAND FILS (*Sci. Ind. Bull.*, 1911, (iii), 2, 1—25).—[JUSTIN DUPONT and LOUIS LABAUNE.]—"Linalyl" bromide, obtained by esterifying either geraniol or linalool (Abstr., 1910, i, 184), condenses with ethyl sodiomalonate to form the ester, $C_{19}H_{27} \cdot CH(CO_2Et)_2$, b. p. 158—159°/5 mm., and this on hydrolysis gives the corresponding acid, $C_{10}H_{17} \cdot CH(CO_2H)_2$, which on distillation under reduced pressure furnishes the monobasic acid,

b. p. 145—146°/5 mm., the ethyl ester of which has b. p. 127—128°/5 mm. The $C_{10}H_{17}$ group in the ester does not appear to have the geranyl configuration, since it is unaffected by sulphuric acid of 66° Bé. On reduction with sodium in alcohol, the ester yields a new alcohol,

$C_{10}H_{17}CH_2CH_2OH$, D^{20}_D 0.8956, n^{20}_D 1.4755, b. p. $110^\circ/5$ mm., which gives a crystalline pyruvate, b. p. $135^\circ/6$ mm., the semicarbazone of which crystallises from alcohol and melts at 103° . The alcohol is converted into the corresponding alcohol by Sabatier and Senderens' method. All these substances possess weak and not very characteristic odours.

Linalyl bromide condenses similarly with ethyl sodioacetate to form the ester, $C_{10}H_{17}CHAcCO_2Et$, b. p. $145^\circ/6$ mm., which on hydrolysis by potassium hydroxide in alcohol gives the ketone, $C_{10}H_{17}CH_2Ac$. The latter was not obtained pure, but it gives a semicarbazone, m. p. 86° , and on oxidation yields lactic acid as chief product.

Ruta montana from Algeria furnishes an oil, D^{20}_D 0.8307, n^{20}_D 1.4742, soluble in 2.25 vols. 70% alcohol, which contains about 90% of methyl nonyl ketone. *Ruta bracteosa* from Algeria gives an oil, D^{20}_D 0.8410, n^{20}_D 1.4712, soluble in two vols. 70% alcohol, and containing 90% of ketones. This oil differs also from the foregoing in congealing partly at -5° , whilst the first oil is solid at $+10^\circ$.

Inula viscosa oil from Algeria had D^{20}_D 0.9436, n^{20}_D 1.4740, and consisted chiefly of cineol.

Syrian origanum oil had D^{20}_D 0.9309 and n^{20}_D 1.466, and was soluble in 1.2 or more vols. 80% alcohol; on standing it deposited a translucent "camphor." Syrian thyme oil, D^{20}_D 0.9120, n^{20}_D 1.4556, contained 43% phenols, composed of thymol and carvacrol. Syrian sage oil, D^{20}_D 0.9843, n^{20}_D 1.4688, was soluble in 1.5 or more vols. of 70% alcohol. Syrian laurel-leaf oil had D^{20}_D 0.9161 and n^{20}_D 1.4220, and was soluble in one or more vols. of 80% alcohol. Syrian neroli oil, D^{20}_D 0.8752, n^{20}_D 1.466, saponification number 51.5, is similar to French neroli oil, constants. Syrian petit-grain oil had D^{20}_D 0.8857, n^{20}_D 1.4624, saponification number 77.4, and was soluble in 1.25 or more vols. of 70% alcohol.

T. A. H.

Essential Oil of *Bupleurum fruticosum*. II. LUIGI FRANCESCONI and G. SANNA (*Gazzetta*, 1911, 41, i, 796—813. Compare the vol., i, 658).—By fractional distillation of the essential oil of *Bupleurum fruticosum*, a large amount of a terpene is obtained as a mobile, colourless liquid, b. p. 167 — 169° , D^{20}_D 0.8416, n^{20}_D 1.4502, which polymerises at 200° . The polymeride is a white, amorphous substance, m. p. 90 — 100° (becoming yellow), n^{20}_D 1.4614 (in chloroform solution). The action of bromine on the terpene yields a colourless, viscous, non-crystalline substance, the amount of bromine absorbed indicating that the substance contains two double linkings. Hydrogen chloride also gives a non-crystalline product. With nitrosyl chloride, a small quantity of a substance was obtained, crystallising in small prisms, which begin to melt at 97° , and are entirely decomposed at 102° . When the residue from this reaction is distilled in steam, an oil is obtained, b. p. about 200° (partial rectification), which is dextrorotatory in alcoholic solution. The action of hydrazine and of phenylhydrazine does not yield crystalline compounds, but semicarbazide gives a semicarbazone, which forms silvery scales, m. p. 197 — 198° , and is dextrorotatory.

The essential oil also contains an alcohol and an ether. R. V. S.

Extraction of an Aldehydic Perfume from Pine-wood Tar. FREDERICK MÜLLER (D.R.-P. 234794).—The fractional distillation of pine-wood-tar furnished at 150–200° substances of aldehydic nature and powerful odours, an aldehyde thus obtained formed a light brown oily liquid of high refractive index and characteristic odour; the crude distillate (b. p. 168–185°) after refractionation had b. p. 170–175° under atmospheric pressure, 75–85°/23 mm. and 51–56°/7 mm. with D_{20}^{25} 1.117. The semicarbazone, m. p. 184–186°, rhombic crystals; and an acime, b. p. 170° (about) and D_{20}^{25} 0.8388 were also prepared. F. M. G. M.

Analysis of a Resin from an Egyptian Sarcophagus. REUTTER (*Compt. rend.*, 1911, 153, 597–599).—The resin from a sarcophagus of the thirtieth dynasty has been shown to contain gum styrax from *Liquidambar orientalis*, Aleppo resin from *Pinus halepensis*, mastic from *Pistacia lentiscus*, cedar wood oil, and asphalt. The ash contained sodium, calcium, aluminium, magnesium, traces of arsenic, chromium, iron, and manganese, carbonates, silicates, phosphates, chlorides, sulphates, and nitrates. The resin also contained sand, vegetable particles, and mineral fragments, of which an account is given. W. O. W.

Constituents of Guayule, *Parthenium argentatum*. P. ALEXANDER (*Ber.*, 1911, 4, 2320–2328).—This investigation was undertaken to ascertain, if possible, whether this plant, which is the source of guayule caoutchouc, contains any substance which can be regarded as the raw material from which caoutchouc is formed in plants. The results were negative from this point of view.

Guayule contains about 8–10% of caoutchouc, expressed on the dry material. The commercial caoutchouc from this source contains 7% of caoutchouc hydrocarbons, and does not differ from "hard Para rubber" to any greater extent than other second class rubbers. The dry plant yields about 6.5% of dark green, extractive matter to acetone, and of this 54%, 31%, and 15% are successively dissolved by light petroleum, ether, and hot alcohol, and of the three component parts thus separated, 12.1%, 7.0%, and 2.0% respectively consist of "unsaponifiable matter." The acids produced on hydrolysis of the extract include one melting at 119° and belonging to the cinnamic acid group, and phenylacetic acid. Weil states (*Priv. com.*) that he has found cinnamic acid in the products of hydrolysis of resin from guayule. The crude acetone extract on distillation with steam gives a *sesquiterpene alcohol*, m. p. 127–128°, with a camphoraceous odour.

On distillation with steam, guayule yields from 0.5 to 4% of volatile oil, D_{20}^{25} 0.8861, which is levorotatory, possesses a peculiar pepper-like aroma, and consists almost wholly of hydrocarbons. On fractional distillation it gives 30%, b. p. 50–60°/17 mm.; 20.3%, b. p. 60–80°/17 mm.; 24.8%, b. p. 120–160°/17 mm., with 5% of resinous residue. The first fraction is mainly *L*-pinene, and the third fraction a *sesquiterpene*, D_{20}^{25} 0.9349, $[\alpha]_D^{25}$ – 21°24', n_D^{25} 1.496. No styrene is present. The above relates to oil distilled from guayule in a fairly fresh state. Oil distilled from plants which had been stored several

years contained much oxygenated material, and although pinene was obtained from this oil no sesquiterpene fraction could be isolated. The presence of volatile oil in guayule is the cause of the difficulty at first experienced in the industrial use of caoutchouc from this source, since the oil hinders vulcanisation.

T. A. H.

Cerebrosides of the Brain. HERMANN LÖNNING and HANS THIERFELDER (*Zeitsch. physiol. Chem.*, 1911, 74, 282—289).—Methods are described for obtaining pure the galactoside known as cerebroses (Thudichum's phreno-in). The presence of other galactosides of the nature of Thudichum's kersin was also found. The work is to be carried further.

W. D. H.

Saponins. RUDOLF KOBERT (*Chem. Zentr.*, 1911, 1, 1589; from *Univ. Festschrift*, 1911, 1, 161—183).—Tables are given in the original of the chief members of the saponin series, $C_nH_{2n-6}O_{10}$, as well as of those of the digitonin series, $C_nH_{2n-10}O_{28}$, of the primary saponogens (secondary glucosides), $C_nH_{2n-6}O_7$, and endsapogenins, $C_nH_{2n-6}O_5$, and also of sapogenins, $C_nH_{2n-10}O_5$.

E. F. A.

Artemisinphenylhydrazone. PASQUALE BERTOLO (*Gazzetta*, 1911, 41, i, 705—708. Compare Abstr., 1901, i, 718; 1908, i, 569).—*Artemisinphenylhydrazone*, $C_{17}H_{19}O_5 \cdot N \cdot NHPh$, crystallises in yellowish white, feathery needles, m. p. 144—145° (rapid heating), 221—222° (slow heating); $[\alpha]_D^{20} + 180^\circ$ (in alcohol). After the substance has been kept at 160° for a few minutes, the rotatory power is unchanged. The compound dissolves in concentrated sulphuric acid, giving a green coloration, which becomes cherry-red on addition of a trace of nitric acid. The phenylhydrazone differs from artemisin in that it is not acted on by alkalis. Prolonged reduction with sodium amalgam yields an acid substance.

R. V. S.

The Chlorophyll Group. The Duality of the Chlorophyllans and alloChlorophyllan. LEON MARCHLEWSKI and J. MARZALEK [with Z. LEVKO] (*Biochem. Zeitsch.*, 1911, 35, 413—433).—Crude chlorophyll solutions from different sources, and even from the same plants, react in different ways when treated with zinc hydroxide and carbon dioxide. The chlorophyll from stinging nettles gives after treatment with these reagents for one day a fairly rapid change, but only a slight precipitate which has not the character of a zinc salt. In the chlorophyll, on the other hand, from maple leaves (*Acer pseudoplatanus*), only a small amount of the material enters into reaction with the zinc salt, and by such treatment the part which does not enter into combination can be separated from the other part. The "zinc chlorophyll" prepared from nettles contains more methoxyl and phytol when zinc acetate is employed for its preparation than when zinc hydroxide is used, and the latter exerts a slight hydrolytic action. The spectral measurements and extinction coefficients of this zinc derivative are given in some detail. Chlorophyllans were prepared from leaves of *Acer platanoides* from Poland and *A. pseudoplatanus* from Galicia, and analyses are given of the products obtained and also spectroscopic measurements. The analyses do not differ markedly from one another.

spectroscopic measurements of the preparation from *A. platinoide*s intermediate between those obtained from nettles and maple. It is concluded that there is here a mixture of two chlorophyllans (chlorophyllan and allochlorophyllan), and that certain varieties of plants are rich in the latter substance. By the separation of chlorophyllan by means of zinc hydroxide and carbon dioxide from allochlorophyllan (the method for which is given in detail) in a preparation rich in the latter and obtained from *A. platinoide*s, a specimen of allochlorophyllan was obtained of which the properties and spectroscopic measurements are given in some detail; this on saponification yields allochlorophyllanic acids. These are reddish (and not olive-green) substances, from which fractions can be obtained by treating the general solution with hydrochloric acid in various strengths. Only when 5% acid is used is any appreciable quantity of the pigment liberated, and the basic character is therefore weak. By 7% acid a preparation of crystalline form was obtained.

S. B. S.

Lakes. I. PAUL PRIFFER (with Z. GOLDBERG and J. KUNTNER) (Ber., 1911, 44, 2653—2662).—The author hopes to bring Tschugueff's (Abstr., 1907, i, 17, 392, 830) and Werner's (Abstr., 1908, i, 441) theories of the constitution of lakes into line with the theory by which he explains the phenomena of halochromy (Abstr., 1910, i, 852; this vol., 788). With this object in view, he has prepared, by heating the following *o*-hydroxy-ketones with tin tetrachloride (1.5 to 2 mols.) in dry benzene on the water-bath, coloured substances, which are represented by the annexed constitution. These substances are closely allied to the lakes of the tin series, which are obtained by replacing the chlorino atoms by hydroxyl groups. The important question whether the tin is united co-ordinatively with the carbonyl oxygen atom is answered in the affirmative, not only because the author has already shown (*loc. cit.*) that carbonyl compounds of the most diverse character exhibit quite universally a tendency to unite co-ordinatively with tin tetrahalides, but also for the following reason. *m*- and *p*-Hydroxyacetophenone and tin tetrachloride in benzene, cold or hot, form normal additive compounds, $\text{Cl}_4\text{Sn} \cdot \text{O} \cdot \text{CMe} \cdot \text{C}_6\text{H}_4 \cdot \text{OH}$ and $\text{O} \cdot \text{CMe} \cdot \text{C}_6\text{H}_4 \cdot \text{OH}$; *o*-hydroxyacetophenone and tin tetrachloride form in cold benzene a mixture of the normal additive compound and of the substituted compound, which evolves hydrogen chloride by warming, and changes entirely to the substituted compound, $\text{C}_6\text{H}_4\text{O} \cdot \text{SnCl}_3$, yellow crystals, m. p. about 238°.

In a similar manner, *o*-hydroxybenzophenone yields the similarly constituted substance, $\text{C}_6\text{H}_4\text{Bz} \cdot \text{OSnCl}_3$, pale yellow leaflets containing $1/2\text{H}_2\text{O}$, m. p. about 250° to a brown liquid; resacetophenone yields the substance, $\text{OH} \cdot \text{C}_6\text{H}_3\text{Ac} \cdot \text{OSnCl}_3$, pale yellow crystals, m. p. 235—248° to a red liquid (the additive compound, $2\text{C}_6\text{H}_3\text{Ac}(\text{OH})_2 \cdot \text{SnCl}_4$,

is precipitated first, and then changes to the substituted compound; quinacetophenone yields the substance, $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{Ac}\cdot(\text{OSnCl}_2)_2$, yellow prisms; euranthone yields the substance,

orange-yellow crystals; gallacetophenone yields the substance,

deep yellow powder; and gallobenzophenone yields the substance,

Of course, in all of these substances the tin is attached to ordinarily to the carbonyl oxygen atom.

Aniline Black and its Intermediate Products. ARTHUR G. GREEN and SALOMON WOLFF (*Ber.*, 1911, 44, 2570, 2582). In connexion with the series of quinonoid derivatives constituting the primary oxidation products of aniline, the various points of controversy between Green and Willstätter appear to turn on the claim of Willstätter and Dorogi (*Abstr.*, 1909, i, 535, 975) that the triquinonoid black is identical with emeraldine [which is diquinonoid according to Green and Woodhead (*Trans.*, 1910, 97, 2388)], but in the formula of Green and Woodhead's nigraniline; or, generally, the number of quinonoid nuclei in Willstätter's series of primary oxidation products of aniline is one greater than the number in Green's series. Willstätter and Cramer (this vol., i, 90) confirm Willstätter and Dorogi's views by estimating the number of quinonoid nuclei by means of phenylhydrazine at temperatures up to 150°. The authors now show that the phenylhydrazine process, although giving good results below 90°, is quite inaccurate at temperatures above 100°, owing to the spontaneous decomposition of the phenylhydrazine; emeraldine or nigraniline is completely reduced to the leuco compound by phenylhydrazine at 80–90°, but when this temperature is exceeded a further evolution of nitrogen occurs without any further change in the reduced product.

In the preparation of their quinonoid blacks, Willstätter and Dorogi submit the product to a prolonged treatment with sulphuric acid. The authors condemn this process, since its effect is to convert triquinonoid and tetraquinonoid blacks into a mixture of emeraldine and polymerisation or decomposition products insoluble in 80% acetic acid. Dichromate black, prepared by Willstätter and Dorogi's method, omitting the acid treatment, is identical with Green and Woodhead's emeraldine; it dissolves completely in 80% acetic acid forming a pale green solution, and yields by treatment with phenylhydrazine at 80–90° a volume of nitrogen corresponding with the diquinonoid formula. The preceding remarks serve to answer most of the recent criticisms of Willstätter and Cramer (this vol., i, 736). Their contention that Green and Woodhead's leucoemeraldine is the real leuco-base, but is a monoquinonoid black, $\text{C}_{48}\text{H}_{40}\text{N}_8$, is regarded as extremely improbable. C. S.

Dimethylpyrone. ADOLF VON BAEYER and JEAN PICCARD (*Annalen*, 1911, 394, 208—224).—2:4:6-Trimethylpyroxonium perchlorate, $\text{CMe} \begin{array}{c} \text{CH} \cdot \text{CMe} \\ \text{CH} \cdot \text{CMe} \end{array} \text{O} \cdot \text{ClO}_4$, colourless, indistinct prisms, m. p.

141—151° (decomp.), is obtained under the following definite conditions: A solution of dimethylpyrone in dry anisole at the ordinary temperature is cooled in a freezing mixture and treated with ethereal magnesium methyl iodide within the course of a minute. After one minute the mixture is added to 20% perchloric acid at -10°, and the perchlorate begins to crystallise almost immediately. 4-Phenyl-2:6-dimethylpyroxonium perchlorate, $\text{C}_{13}\text{H}_{13}\text{O}_3\text{Cl}$, sulphur-yellow leaflets, m. p. 210—212° (decomp.), is prepared in a similar manner; the perchlorate, $\text{C}_{13}\text{H}_{13}\text{O}_3\text{N}_3$, has m. p. 193°. All pyroxonium salts are converted into the corresponding pyridine compounds by aqueous ammonia in the cold; thus trimethylpyroxonium perchlorate yields 2:4:6-trimethylpyridine (perchlorate, m. p. 243—244°), the methiodide of which is converted by aqueous perchloric acid into 1:2:4:6-tetramethylpyridinium perchlorate, $\text{C}_9\text{H}_4\text{O}_4\text{NCl}$, m. p. 206—207°, which is also produced from trimethylpyroxonium perchlorate and methylamine. Trimethylpyroxonium perchlorate is converted by boiling alcoholic *p*-toluidine into 1-*p*-tolyl-2:4:6-trimethylpyridinium perchlorate, $\text{CMe} \begin{array}{c} \text{CH} \cdot \text{CMe} \\ \text{CH} \cdot \text{CMe} \end{array} \text{N}(\text{C}_6\text{H}_4) \cdot \text{ClO}_4$, m. p. 141—142°, whilst

phenyldimethylpyroxonium perchlorate is converted similarly into 4-phenyl-1-*p*-tolyl-2:6-dimethylpyridinium perchlorate, m. p. 205°.

When an aqueous solution of trimethylpyroxonium perchlorate is boiled with barium carbonate in a current of hydrogen, δ -methyl- Δ^7 -hepten- $\beta\gamma$ -dione, $\text{COMe} \cdot \text{CH} \cdot \text{CMe} : \text{CH} \cdot \text{COMe}$, is obtained as an unstable oil, which has an odour of peppermint, regenerates the original perchlorate by warming with dilute perchloric acid, and forms a disemicarbazone, $\text{C}_{10}\text{H}_{18}\text{O}_2\text{N}_2$, m. p. 210—210.5°. δ -Phenyl- Δ^7 -hepten- $\beta\gamma$ -dione, m. p. 51°, obtained in a similar manner from phenyldimethylpyroxonium perchlorate, is an unstable, colourless, crystalline powder. By reduction with palladium chloride and gum arabic in an atmosphere of hydrogen, it yields δ -phenylheptane- $\beta\gamma$ -dione,

m. p. 61—62°. δ -Methylheptane $\beta\gamma$ -dione, b. p. 95—96°/12 mm., obtained in a similar manner, reacts very readily with semicarbazide, forming the disemicarbazone, $\text{C}_{10}\text{H}_{20}\text{O}_2\text{N}_2$, m. p. 199°. None of these δ -diketones give a reaction with ferric chloride. C. S.

β -Phenylcoumarins. I. GUIDO BARGELLINI and G. LEONARDI (*Gazzetta*, 1911, 41, i, 737—746).—In the hope of obtaining compounds related to certain substances found in plants, the preparation of some hydroxyl derivatives of β -phenylcoumarin has been undertaken, using an old method for the preparation of coumarin derivatives (compare Komarovski and von Kostanecki, Abstr., 1894, i, 506).

2:3:4-Trihydroxybenzophenone, when heated for twenty hours with sodium acetate and acetic anhydride, yields the diacetyl- β -phenyl-daphnetin of von Kostanecki and Weber (Abstr., 1894, i, 88).

2:4-Dihydroxy-4'-methoxybenzophenone (Komarovski and von

Kostanecki, *loc. cit.*) when heated for twenty hours with sodium acetate and acetic anhydride yields (1) a substance, probably the diacetyl derivative of 2:4-dihydroxy-4'-methoxybenzophenone; and (2) an acetyl derivative of 4-hydroxy-4'-methoxy- β -phenylcoumarin, $C_{18}H_{14}O_5$, which forms colourless, woolly needles, m. p. 185—185°. By dissolving this substance in concentrated sulphuric acid and pouring the solution into water, 4-hydroxy-4'-methoxy- β -phenylcoumarin, $C_{16}H_{12}O_4$, is obtained; it forms yellowish-white needles, m. p. 261—263°. The compound dissolves in alkalis, giving yellow solutions with a green fluorescence; the solution in alcohol is also fluorescent, but the fluorescence disappears on the addition of acid. The substance dissolves in concentrated sulphuric acid, giving a green coloration. When it is treated with methyl iodide, 4:4'-dimethoxy- β -phenylcoumarin, $C_{17}H_{14}O_4$, m. p. 156°, is obtained.

2:4:4'-Trihydroxybenzophenone yields, when heated with sodium acetate and acetic anhydride, (1) triacetoxybenzophenone, which forms colourless needles, m. p. 96—98°; (2) 4:4'-diacetoxy- β -phenylcoumarin, $C_{16}H_{12}O_6$, which crystallises in colourless needles, m. p. 189—189°. 4:4'-Dihydroxy- β -phenylcoumarin, $C_{15}H_{10}O_4$, prepared from it, forms yellowish-white needles, m. p. 238—240°. When treated with methyl iodide, it yields 4:4'-dimethoxy- β -phenylcoumarin, previously described.

R. V. S.

β -Phenylcoumarins. II. GUIDO BARGELLINI and G. FORTI (Gazzetta, 1911, 41, i, 747—756. Compare preceding abstract).—The synthesis of β -phenylcoumarins has been continued by another method (compare von Kostanecki and Weber, Abstr., 1894, i, 882), namely, the condensation of *p*-cyanoacetylanisole or cyanoacetylveratrole (1:2-dimethoxy-4-cyanoacetophenone) with resorcinol or phloroglucinol.

p-Cyanoacetylanisole, $C_{10}H_9O_2N$ (from *p*-chloroacetylanisole and potassium cyanide), crystallises in tufts of long, colourless needles, m. p. 128—130°. When it is heated with resorcinol and 75% sulphuric acid on the water-bath, two products are obtained: (1) a substance, soluble in water, which forms colourless needles, m. p. 234—236°, and is probably the nitrile or amide of the coumarin derivative, m. p. 260—262°, which it yields on addition of hydrochloric acid; (2) 4-hydroxy-4'-methoxy- β -phenylcoumarin, m. p. 260—262°, identical with that described in the preceding abstract.

Condensation of *p*-cyanoacetylanisole with phloroglucinol yields a substance, m. p. about 200°, from which an acetyl derivative can be prepared, which crystallises in colourless needles, m. p. 179—180°.

Chloroacetylveratrole can be obtained: (1) by the action of methyl sulphate on chloroacetylcatechol; and (2) by condensation of chloroacetyl chloride with veratrole in presence of aluminium chloride. In the second case another substance (? *chloroacetylguaiacol*) is the principal product; in both cases the yield is exceedingly small. Chloroacetylveratrole, $C_{10}H_{11}O_3Cl$, crystallises in white scales, m. p. 102—104°. Cyanoacetylveratrole, $C_{11}H_{11}O_3N$, forms colourless needles, m. p. 134—135°. With resorcinol in presence of 75% sulphuric acid, it yields a substance, which crystallises in yellowish-

white needles, m. p. 228—239°, whilst with phloroglucinol a reddish-brown condensation product is obtained.
R. V. S.

Preparation of Phenothioxin and its Derivatives. AKTIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION (D.R.-P. 234743).—It is found that the phenothioxin, m. p. 60—61°, b. p. 183—184°/12 mm., prepared by Mauthner (Abstr., 1906, i, 448) can be readily obtained by heating (with continual stirring) phenyl ether at 60—70° with sulphur in the presence of aluminium chloride; the temperature is subsequently slowly raised to 100° and maintained until evolution of hydrogen sulphide ceases. Under these conditions, *p*-tolylphenyl ether yields 3-methylphenothioxin (annexed formula), m. p. 36°, b. p. 185—187°/12 mm., whilst *p*-chlorophenyl ether furnishes 3-chlorophenothiacin, m. p. 37°, b. p. 176°/12 mm.
F. M. G. M.

Preparation of Anthracene Derivatives.] FARBENFABRIKEN VON FRIEDR. BAYER & Co. (D.R.-P. 235094).—When anthraquinone-

1-thiol is heated with 1-hydroxyanthraquinone at 160—170° in 98% sulphuric acid, it yields a compound (annexed formula), which crystallises from hot quinoline in brownish-red needles. The tinctorial properties of this and the following analogous condensation products are tabulated in the original.

1:5-Dithiolanthraquinone with 1- and 2-hydroxyanthraquinones (2 mols.) respectively; 1-thiolanthraquinone (2 mols.) and anthrarufin; 1-thiol-5-aminoanthraquinone and 5-amino-1-hydroxyanthraquinone; 1-thiolanthraquinone with 2-hydroxyanthraquinone; and 1-thiolanthraquinone (2 mols.) with anthraflavic acid; 2-thiolanthraquinone (1 mol.) with 2-hydroxyanthraquinone and (2 mols.) with anthraflavic acid.

Solubility of Alkaloids in an Aqueous Boric Acid-Glycerol Solution. E. BARONI and O. BORLINETTO (*Chem. Zentr.*, 1911, ii, 93—94; from *Giorn. Farm. Chim.*, 1911, 60, 193—195).—A solution containing 3.0 grams of boric acid, 50.0 grams of glycerol, and water to 100 c.c., dissolves the following quantities of various alkaloids, the figures in parentheses giving the solubility of the respective alkaloids in water: Codeine, 4% (1.66%); atropine, 10% (0.5%); cocaine, 8% (0.14%); morphine, 5.5% (0.1%); strychnine, 3.5% (trace); eserine, 7.5% (trace); veratrine, 6% (trace). The solubility of the alkaloids increases with the proportion of boric acid present in the solution.
W. P. S.

Crystalline Alkaloid of Calycanthus glaucus. IV. Some Salts of a New Quaternary Base obtained by Methylating iso-Calycanthine. HARRY M. GORDIN (*J. Amer. Chem. Soc.*, 1911, 33, 1626—1632).—When isocalycanthine (Abstr., 1910, i, 62) is treated

with methyl iodide, about 35% of the alkaloid is converted into the hydriodide, about 35% remains unchanged, and the remainder is converted into a quaternary iodide, $C_{11}H_{14}ON_2I, H_2O$. It is suggested that the oxygen of the air takes part in the reaction, as shown by the equations: $2C_{11}H_{14}N_2 + 2MeI + O_2 = C_{11}H_{14}ON_2I, H_2O + NH_3$ and $C_{11}H_{14}N_2 + NH_4I = C_{11}H_{14}N_2HI + NH_3$.

The quaternary iodide forms white, flat, lustrous needles, becomes brown at 213—214°, does not melt below 325°, and is soluble in about 30 parts of hot methyl alcohol; its hydriodide is described. The corresponding chloride, $C_{11}H_{14}ON_2Cl, 3H_2O$, m. p. 220°, crystallises in flat, lustrous needles, and is soluble in about 50 parts of cold water; its hydrochloride is described. The nitrate, $C_{11}H_{14}ON_2, NO_3$, m. p. 192—194°, forms white, rectangular prisms. The quaternary picrate, m. p. 155°, and picrolonate, m. p. 164—166°, are also described.

E. G.

Colchicine. I. and II. ADOLF WINDAUS (*Chem. Zentr.*, 1911 i, 1637—1638, 1638—1641; from *Sitzungsber. Heidelberger Akad. Wiss.*, 1910, 1—7; 1911, 1—27).—On oxidation of colchicine in

potassium hydroxide with potassium permanganate, in addition to oxalic acid, trimethoxy-*o*-phthalic acid, $C_{11}H_{12}O_7$, is obtained, which must have the anhydride structure, since it differs from the trimethoxy-*o*-carboxylic acid described by Feist.

By cautious sublimation of the reaction product in a vacuum at 220°, the anhydride, $C_{11}H_{12}O_7$, is obtained in needles, m. p. 143—144°. This is converted into the acid when boiled with water, which crystallises in transparent plates, m. p. 175—176°; the silver and lead salts are insoluble; the barium salt forms needles. The anil crystallises in colourless needles, m. p. 165°.

Derivatives of Trimethylcolchicine Acid.—Colchicine was regarded by Zeisel as the methyl ester of an acid, colchiceine, but it is now considered to be an enolic methyl ether, colchiceine being an enol, since it gives a characteristic green coloration with ferric chloride. Zeisel has shown further, that colchiceine contains an acetyl group attached to nitrogen, so that the structure of colchicine may be expressed $C_6H(OMe)_3, C_{10}H_8O(OMe) \cdot NH \cdot COMe$.

The almost colourless aqueous or alcoholic solutions of colchicine and its derivatives become deep yellow on the addition of hydrochloric acid, owing to the formation of acid additive products. *Trimethylcolchicine acid dihydrochloride*, $C_{10}H_{21}O_2N, 2HCl, H_2O$, forms dark yellow crystals; it still contains the free enolic group, and when heated at 100°, regenerates the monohydrochloride. *Trimethylcolchicine acid dibenzoate*, $C_6H(OMe)_3, C_{10}H_8O(O \cdot CPh) \cdot NH \cdot CPh$, crystallises in faint yellow, three-sided prisms, m. p. 298° (decomp.); it gives no coloration with ferric chloride. *N-Benzoyltrimethylcolchicine acid*, $C_6H(OMe)_3, C_{10}H_8O(OH) \cdot NH \cdot CPh$, prepared by heating the dibenzoate with 25% potassium hydroxide, separates in pale yellow needles, m. p. 253—254°, and gives a dark green ferric chloride coloration.

N-*p*-Benzoyltrimethylcolchicine acid forms prisms, m. p. 256°.

p-Benzoyltrimethylcolchicine acid separates in platelets, m. p.

35°. *N*-Benzenesulphonyltrimethylcolchicine acid,

is greenish-yellow, rhombic plates, m. p. 255°, and gives an intense ferric chloride reaction. Trimethylcolchicine acid dibenzoyl derivative, prepared by the action of benzenesulphonyl chloride on the hydrochloride in pyridine solution, crystallises in yellow, four-sided, rhombic plates, m. p. 196°. The mother liquors contain an isomeric benzenesulphonate, crystallising in greenish-yellow prisms and plates, m. p. 141–142°. Neither isomeride gives any coloration with ferric chloride, and they are regarded as *cis*, *trans*-isomerides.

Preparation of Colchicine Derivatives with Potassium Permanganate.—By cautious oxidation with potassium permanganate, a lactone, *colchide*,

N-Benzoylcolchide, $C_{23}H_{23}O_5N$ (annexed formula), formed on oxida-

tion of *N*-benzoyltrimethylcolchicine acid, forms needles, m. p. 239°, $[\alpha]_D^{25} = -275^\circ$; it gives no coloration with ferric chloride, and is neutral towards litmus paper. On further oxidation trimethoxyphthalic acid is formed. It dissolves in alcoholic potassium hydroxide, the equilibrium between hydroxy-acid and lactone depending on the amount of alkali present. When heated for two hours at 250° under diminished pressure, benzamide and trimethoxyphthimonaphthide, $C_{16}H_{16}O_5$, are obtained. The latter (annexed formula) crystallises in needles, m. p. 138°, is optically inactive, and behaves as a lactone; it is also

formed on boiling *N*-benzoylcolchide with alcoholic hydrogen chloride, whereby, in part, benzoic acid and the corresponding amine, colchide, are formed; *colchide picrate*, $C_{16}H_{15}O_5N \cdot C_6H_3O_7N_3$, crystallises in yellow prisms, m. p. 165°.

N-Benzoylcolchicine anhydride (annexed formula), prepared by oxida-

tion of *N*-benzoyltrimethylcolchicine acid, forms straggling, four-sided platelets, m. p. 207°, $[\alpha]_D^{25} = -288^\circ$. The solutions in water and organic solvents are intense yellow, but the alkali salt solutions are colourless and remain so at first on the addition of acid; later they become yellow, and the anhydride crystallises. The *anil*, $C_{29}H_{26}O_6N_2$, forms almost colourless needles, m. p. 226°.

On heating with zinc dust and acetic acid, a tetrahydronaphthalene

derivative, $C_{22}H_{22}O_8N$, probably having the formula

is obtained; it separates in colourless needles, m. p. 158° , after previously sintering.

When the anhydride is warmed with hydriodic acid, the methyl groups and carbon dioxide are eliminated, and a compound, $C_{12}H_{12}N_2$, having possibly the structure

formula is obtained; it crystallises in colourless needles, which darken at 200° , decomp. 230° .

The reasons for assuming the formula given to benzoylcolchicine anhydride are discussed at length.

N-Acetylcolchide forms needles, m. p. 221° ; the lactone ring is only opened with difficulty.

N-Acetylcolchicine anhydride forms deep yellow needles, m. p. 201° , and dissolves without colour in alkali hydroxides.

N-Benzenesulphonylcolchicine anhydride, $C_{28}H_{24}O_8NS$, crystallises in long, four-sided plates, m. p. $242\text{--}243^\circ$ (decomp.). When hydrolysed and again acylated, it is converted into *N*-benzoylcolchicine anhydride.

E. F. A.

Preparation of Hydrastinine Salts. HERMAN DECKER (DEP. 234850. Compare Abstr., 1908, i, 901).—When formylhomopiperonylamine, $CH_3 \cdot O_2 \cdot C_6H_3 \cdot CH_2 \cdot CH_2 \cdot NH \cdot COH$, needles, m. p. $51\text{--}52^\circ$, prepared by heating homopiperonylamine formate at $160\text{--}170^\circ$, and

heated with phosphoric oxide, it yields 6:7-methylenedioxy-3:4-dihydroisoquinoline (at nexted formula), nodular crystals, m. p. $69\text{--}70^\circ$; its salts exhibit blue fluorescence, and the picrate has m. p. 238° ; on treatment with methyl iodide, it furnishes hydrastinine

hydriodide, and with methyl sulphate yields hydrastinine methylsulphate, a yellow powder, m. p. $117\text{--}119^\circ$; the picrate has m. p. 175° .

F. M. G. M.

Action of Organic Magnesium Compounds on Hydrastinine. MARTIN FREUND and KARL LEDERER (Ber., 1911, 44, 2356--2362).

—Hydrastinine interacts with organo-magnesium compounds in a similar manner to cotarnine (Freund and Reitz, Abstr., 1906, i, 670), forming α -alkylhydrohydrastinine compounds of the type

these are 1-alkyltetrhydroisoquinoline derivatives. Free hydrastinine gives a 50% yield; the hydrochloride reacts quantitatively with the Grignard reagent.

α -Methylhydrohydrastinine is an oil; the hydriodide crystallises in plates, m. p. 227° ; the methiodide also forms plates, m. p. $229\text{--}230^\circ$.

α -Ethylhydrohydrastinine crystallises in hard, colourless plates, m. p. $70\text{--}71^\circ$.

- a. Phenylhydrodrastinine* + H_2O forms long, pointed crystals, m. p. 182°; the anhydrous substance forms a yellow, resinous mass.
- a. Propylhydrodrastinine* is oily; the *hydriodide* crystallises in plates, m. p. 185—186°; the *platinichloride* forms rhombic crystals, decomp. 230°; the *methiodide* separates in plates, which sinter at 163°, m. p. 168—169°.
- a. Isobutylhydrodrastinine* is likewise oily. The *hydrobromide* crystallises in pointed needles, m. p. 190°; the *hydriodide* forms colourless, rhombic plates, m. p. 217—218°; the *picrate* forms plates, m. p. 143—145°; the *platinichloride* separates in needles, m. p. 223°; the *methiodide* forms bunches of needles, m. p. 219—220°.
- a. Ethylhydrodrastinine* is oily; it is characterised by the *picrate*, plates, m. p. 147—148°; the *platinichloride*, rhombic plates, m. p. 220—223°; and the *methiodide*, leaflets, m. p. 205—206°.
- a. Isoamylhydrodrastinine* gives a *picrate*, crystallising in prisms, which sinter at 125°, m. p. 130°; a *platinichloride*, separating in four-sided plates, decomp. 220°, and a *methiodide*, which forms bunches of leaflets, m. p. 197—198°.
- a. Benzylhydrodrastinine* is an oil, but forms crystalline salts. The *hydrochloride* forms six-sided crystals, m. p. 182°; the *hydrobromide* has m. p. 187—188°; the *hydriodide* crystallises in hexagonal plates, m. p. 195—196°; the *acid sulphate* sinters at 185°, m. p. 189°; the *picrate* forms octahedra, m. p. 178—180°; the *platinichloride* forms plates, decomp. 224°, whilst the *methiodide* forms aggregates of columnar crystals, m. p. 245°.
- a. p. Anisylhydrodrastinine* crystallises in columns united in bundles, m. p. 98—99°; the *hydrochloride* forms needles; the *hydrobromide* is similar, m. p. 243—244°; also the *hydriodide*, m. p. 223—224°.
- a. Naphthylhydrodrastinine* forms rhombic plates, which sinter at 125°, m. p. 127—128°. The *hydrochloride*, m. p. 254—255°; the *hydrobromide*, needles, m. p. 265°; the *hydriodide*, needles, m. p. 262°; the *acid sulphate*, matted crystals, which sinter at 225°, m. p. 228—229° (decomp.), and the *picrate*, plates, decomp. 201°, are described.

E. F. A.

Formation of Alkaloidal Periodides. W. C. HOLMES (*Philippine J. Sci.*, 1911, A, 6, 253—275).—A résumé of the literature relating to the formation of alkaloidal periodides and the use of these compounds in the estimation of alkaloids is given. It is shown that morphine, codeine, and heroine, free or in the form of salts, have a remarkable affinity for iodine, and readily combine with it even in the absence of a solvent. There is no tendency to form definite compounds. The reactions are apparently dependent on the concentration of the iodine, and the phenomena observed are those of equilibrium involving vapour and osmotic pressures as factors. The amount of "free" iodine combined with the alkaloids cannot be determined by thiosulphate solution, and consequently it is considered that the formation and constitution of the periodides are much more complex than has been supposed.

When $N/10$ -iodine solution is added to a 1% solution of codeine,

morphine, or heroine sulphate in *N*/10-sulphuric acid, and the uncombined iodine titrated with *N*/10-sodium thiosulphate after standing overnight, the amounts of iodine absorbed by the alkaloids increase with the total concentration of iodine in the mixed solutions, but a maximum is soon reached in the case of heroine. When other factors are varied and the concentration of iodine and alkaloid kept constant, the amount of iodine absorbed varies inversely with rise in temperature, or increase in concentration of (a) sulphuric acid, (b) potassium iodide. Equilibrium appears to be reached in about thirty minutes. All the codeine precipitates were crystalline, as were also two of the morphine precipitates, whilst with heroine only amorphous deposits were obtained. The belief that in using Wagner's reagent for the estimation of alkaloids a definite amount of iodine combines with the alkaloid and may be determined by titration of the residual iodine is fallacious (compare Prescott and Gordin, *Abstr.*, 1899, i, 89).

Aqueous solutions of free morphine, codeine, and heroine are precipitated by Wagner's reagent, and here, also, the amount of iodine absorbed is proportional to the concentration of iodine, and is inversely proportional to the amount of acid, which may be added subsequently. The free alkaloids and their sulphates also absorb iodine vapour when exposed to it, the salts being distinctly less active than the free bases.

T. A. H.

Methylation of the Alcoholic Hydroxyl Group in Morphine, Codeine, and the Methylmorphimethines. ROLAND PASCHOK and F. DICKHAUSEN [and, in part, C. D'AVIS] (*Ber.*, 1911, 44, 2633-2640).—The alkylation of the alcoholic hydroxyl group in morphine, which has not hitherto been effected, proceeds quite easily in the cold when the alkaloid is shaken with methyl sulphate or methyl iodide and *N*-sodium hydroxide (2½ mols.). The product of the reaction, which is also obtained by starting with codeine, is precipitated by concentrated potassium iodide, whereby *methylcodeine methiodide*, decomp. 257° (corr.), $[\alpha]_D^{20} - 107.2^\circ$ in water, is obtained. A boiling aqueous solution of the methiodide is converted by 25% sodium hydroxide into *α-dimethylmorphimethine*, $C_{20}H_{25}O_3N$, leaflets or needles, m. p. 94°, $[\alpha]_D^{20} - 20.1^\circ$ in methyl alcohol (*methiodide*, $C_{21}H_{28}O_3NI$, decomp. 256° (corr.), $[\alpha]_D^{20} - 134.4^\circ$ in water), which is changed by heating with aqueous alcoholic potassium hydroxide or with acetic anhydride at 210° to *β-dimethylmorphimethine*, isolated in the form of the *methiodide*, $C_{21}H_{28}O_3NI$, prismatic needles, decomp. 318-320° (corr.), $[\alpha]_D^{20} 268.5 - 278.5^\circ$ in water.

The methylation of *α*- and *β*-methylmorphimethine is effected as in the case of morphine or codeine, the methiodides obtained being identical with those of *α*- and *β*-dimethylmorphimethine mentioned above. *γ-Dimethylmorphimethine methiodide*, $C_{21}H_{28}O_3NI$, leaflets, has decomp. 259° (corr.) and $[\alpha]_D^{20} + 14^\circ$ in water. *δ-Dimethylmorphimethine methiodide*, needles, has decomp. 286° (corr.), and $[\alpha]_D^{20} 170.9^\circ$ in water. *ε-Dimethylmorphimethine methiodide*, long needles, has decomp. 277° (corr.), and $[\alpha]_D^{20} - 79.4^\circ$ in methyl alcohol.

β-Dimethylmorphimethine methiodide is decomposed by aqueous

alcoholic potassium hydroxide at 165°, forming morphenol, ethylene, and trimethylamine.

The methylation of various alcohols by sodium hydroxide and methyl sulphate has been examined. The method yields good results with benzyl alcohol and cinnamyl alcohol, but is unsatisfactory with *n*-amyl alcohol, octyl alcohol, borneol, and isoborneol. C. S.

Codeine Oxide. MARTIN FREUND and EDMUND SPEYER (*Ber.*, 1911, 4, 2339—2353. Compare this vol., i, 76).—When codeine oxide, dissolved in acetic anhydride, reacts with sulphuric acid, two isomeric substances, $C_{18}H_{20}O_3NS$, are formed, both of which are acid in character, codeinesulphonic acid (I.) and α -codeineoxidesulphonic acid (II.), these probably have the annexed constitutions; the α compound is

asily converted into the isomeride.

On reduction, both are converted into the same codeinesulphonic acid, $\text{N}:[C_{18}H_{20}O_3] \cdot \text{SO}_3\text{H}$. This, on treatment with nitric acid, yields the nitrocodeine described by Anderson. Proof that no change in the structure of the alkaloid complex has taken place is afforded by the fact that all the sulphonic acids described yield codeine when superheated with water. When dissolved in cold concentrated sulphuric acid, the sulphonic acids, however, are more profoundly altered, and new products are obtained which await further investigation.

Codeinesulphonic acid when treated with methyl iodide in alkaline solution forms codeinesulphonic acid methyl hydroxide,

On boiling with alkali, β -dimethylbutylene- β -diamine is eliminated and a nitrogen-free product obtained, which could not be isolated. After remaining in alkaline solution with methyl iodide and alcohol for some time and then boiling, the methyl hydroxide is converted into a crystalline salt, $C_{18}H_{19}O_3SK$, which is regarded as a morphenol derivative, $\text{O}:[C_{18}H_{19}O_3] \cdot \text{SO}_3K$.

α -Codeineoxidesulphonic acid behaves in many respects otherwise than the isomeride. With nitric acid a nitro-compound,

is obtained. Sulphurous acid converts this into a nitrocodeine isomeric with Anderson's, but both isomerides give the same aminocodeine when reduced.

When α -codeineoxidesulphonic acid is treated with bromine water, and the perbromide formed is boiled with alcohol, a compound, $C_{18}H_{17}O_4Br_2$ or $C_{18}H_{15}O_4Br_3$, is obtained of unknown constitution.

Morphine oxide, when similarly treated with acetic anhydride and sulphuric acid, forms a bimolecular hydroxysulphonic acid, $C_{18}H_{21}O_5N_2S_2$, which is converted by sulphurous acid into a compound, $C_{17}H_{21}O_5NS$.

Codeineoxidesulphonic acid forms small crystals of the hexagonal system, decomp. 272°, $[\alpha]_D - 115.4^\circ$, and forms a crystalline potassium salt.

Codeinesulphonic acid is dimorphous, crystallising in well-formed prisms and silky needles, which can be converted into one another. It decomposes above 300° and has $[\alpha]_D - 136.3^\circ$.

Codeinesulphonic acid methylhydroxide separates in needles, decomp. 284° , $[\alpha]_D -63.2^{\circ}$. Treatment with methyl iodide and alcohol and subsequent boiling with alkali gives a compound, $C_{18}H_{21}O_8K$, crystallising in well-formed plates, decomp. 295° . On treatment of codeineoxidesulphonic acid with cold concentrated sulphuric acid, a substance, $C_{18}H_{21}O_8NS$, provisionally termed β -codeinesulphonic acid, is obtained. It forms bundles of microscopic plates, decomp. 243° , $[\alpha]_D -190.1^{\circ}$. Sulphurous acid converts this into an isomeric substance, provisionally termed γ -codeinesulphonic acid, which crystallises in matted needles, decomp. 280° .

Potassium chromate oxidises codeineoxidesulphonic acid into *codeineoxidesulphonic acid hydrate*, $C_{18}H_{23}O_8NS$, crystallising in needles, on heating at 180° with water under pressure, a base separating in stunted, prismatic plates or long needles, m. p. 180° , is obtained. The hydrochloride forms long needles, m. p. 310° .

Concentrated sulphuric acid converts codeinesulphonic acid into a compound, $C_{19}H_{19}O_8N \cdot SO_3H$, which crystallises in very slender needles, decomp. $285-290^{\circ}$.

α -Codeineoxidesulphonic acid crystallises in stunted prisms. It is converted into the isomeride on heating with 10% sodium hydroxide or 20% hydrochloric acid.

Nitro- α -codeineoxidesulphonic acid crystallises in yellow plates, decomp. $167-170^{\circ}$.

α -Nitrocodeine, prepared by the action of sulphurous acid on the sulphonic acid, crystallises in microscopic, four-sided plates, m. p. 197° .

By the interaction of bromine and α -codeineoxidesulphonic acid, a compound, $C_{18}H_{17}O_4Br_2$, is obtained in long needles, m. p. $258-259^{\circ}$ (decomp.).

Codeinesulphonic acid is without physiological action.

Both the isomeric nitrocodeines when reduced electrolytically yield the same aminocodeine, $C_{18}H_{20}O_8N \cdot NH_2$, crystallising in plates, m. p. 228° . The hydrochloride forms needles, m. p. 290° .

Hydroxycodeine, prepared by diazotisation of aminocodeine and boiling, crystallises in colourless plates, which when heated lose water at $176-185^{\circ}$, m. p. 234° . The hydrochloride crystallises in needles.

E. F. A.

Cotarnine. VI. MARTIN FREUND and KARL LEDERER (Ber., 1901, 44, 2353-2356).—Tarconine methiodide reacts with magnesium phenyl iodide, forming 8-methoxy-6:7-methylenedioxy-1-phenyl-2-methyl-

1:2-dihydroisoquinoline, $CH_2 \begin{array}{c} \diagup O \cdot C \cdot C(OMe) \cdot C \cdot CHPh \cdot NMe \\ \diagdown O \cdot C \cdot CH \quad \quad \quad C \cdot CH = CH \end{array}$. On reduction this is converted into α -phenylhydrocotarnine (8-methoxy-6:7-methylenedioxy-1-phenyl-2-methyltetrahydroisoquinoline), previously prepared by Freund and Reitz (Abstr., 1906, i, 600) from cotarnine salts and magnesium phenyl iodide.

α -Phenyltarconine forms colourless bunches of pointed crystals, which sinter at 97° , m. p. 102° . The salts and methiodide are oily and decompose with a red coloration.

α -Butylhydrocotarnine, $CH_2O_2 \begin{array}{c} \diagup C \cdot C(OMe) \cdot C \cdot CH(C_4H_9) \cdot NMe \\ \diagdown C \cdot CH \quad \quad \quad C \cdot CH_2 \quad \quad \quad CH_2 \end{array}$ 1ⁿ

pared from cotarnine hydrochloride and magnesium butyl bromide is an oil. The following crystalline salts have been analysed: *hydrochloride*, plates, m. p. 215—216°; *hydrobromide*, plates, m. p. 207—208°; *hydriodide*, columns, m. p. 190—191°; *picrate*, plates, m. p. 165—166°; *methiodide*, plates, m. p. 205—206°; *methiodide*, long, rhombic plates, m. p. 190—193°.

E. F. A.

Stereochemistry of Nitrogen Compounds. Isomeric Bis-hydrocotarnines. MARTIN FREUND and OTTO KUPFER (*Annalen*, 1911, 384, 1—38).—Bis-hydrocotarnine (di-hydrocotarnine) has been prepared by Freund and Reitz (*Abstr.*, 1906, i, 600), and the constitution ascribed to it by these authors has been confirmed by Freund and Lederer (see Lederer, *Diss.*, Giessen, 1909) and yet again by the present authors, who have oxidised the substance to cotarnine nearly quantitatively by dilute sulphuric acid and 10% potassium dichromate. From its constitution (the molecule consists of two structurally identical halves, each containing an asymmetric carbon atom) it is obvious that a stereoisomeride should exist, and, indeed, a repetition of Freund and Reitz's experiment has shown that, in addition to the bis-hydrocotarnine already isolated, a small quantity of the isomeride, *iso*-bis-hydrocotarnine, $C_{24}H_{28}O_6N_2$, is formed. The two compounds have the same m. p., 163—164° (when mixed m. p. about 20° lower), but show marked dissimilarities in the solubilities of their salts; they are easily separated almost quantitatively by means of their *hydrogen sulphates*, that of bis-hydrocotarnine being very sparingly soluble in dilute sulphuric acid. Bis-hydrocotarnine forms a dihydrochloride, m. p. 231—232°, dihydrobromide, decomp. 228—229°, dihydriodide, m. p. 228—230°, *dihydrofluoride*, m. p. 227—229°, and *dinitrate*, m. p. 169—171°, whilst *iso*-bis-hydrocotarnine forms corresponding salts having the same m. p. (the mixed m. p. is always lower). It is changed to bis-hydrocotarnine at 160°, and gives a quantitative yield of cotarnine by oxidation with potassium dichromate and sulphuric acid.

Possibly bis-hydrocotarnine and *isobis*-hydrocotarnine represent racemic and meso-modifications. However, all attempts to resolve either of them having been unsuccessful, this problem has been put aside for the present, although the suggestion is advanced that the two substances may be *cis*- and *trans*-modifications of the meso-form, as in the case of coniine and *iso*-coniine. *iso*-Bis-hydrocotarnine forms a *methiodide*, $C_{24}H_{28}O_6N_2 \cdot MeI$, m. p. 233°. The fact that bis-hydrocotarnine forms only a monomethiodide (*loc. cit.*) is due to steric hindrance, because when the methiodide is converted into the corresponding *hydrozide*, $C_{24}H_{28}O_6N_2 \cdot MeOH \cdot 10H_2O$, m. p. 75—80°, and this is treated with methyl iodide, the *methiodide*,

m. p. 215—216°, is obtained, which is converted by acetic acid and potassium iodide into *bis*-hydrocotarnine dimethiodide $C_{24}H_{28}O_6N_2 \cdot 2MeI$, m. p. 201—202°.

When treated with silver oxide and water and subsequently boiled with concentrated potassium hydroxide, bis-hydrocotarnine methiodide and *iso*-bis-hydrocotarnine methiodide yield respectively *de-N-methylbis*-hydrocotarnine, $C_{25}H_{30}O_6N_2$, m. p. 120—122° (*dihydriodide*, m. p.

contains only one ionisable bromine atom. Both substances yield cotarnine by oxidation, and form only monomethiodides. *De-N-methyl-*

isobishydrocotarnine, $C_{26}H_{32}O_6N_2$, m. p. 218—220° (*hydriodide*, $C_{26}H_{30}O_6N_2, MeI$, m. p. 156—158°, decomp. 248°), the *methiodide*, $C_{26}H_{30}O_6N_2, MeI$, m. p. 156—158°, which is decomposed by sodium ethoxide, yielding trimethylamine and *cotarnylidene-de-N-methylhydrocotarnine* (see below).

Cotarnylidenehydrocotarnine yields cotarnine by oxidation, and

Bishydrocotarnine dimethiodide, by treatment with silver oxide and

173—175°) and *de-N-methylisobishydrocotarnine*, m. p. 136° (*dihydriodide*, m. p. 146—149°), which are regarded as structural isomerides on account of their different chemical behaviour. Although their constitutions have not been definitely settled, that annexed is ascribed to *de-N-methylbishydrocotarnine*, because the substance reacts with bromine to form an additive compound, $C_{26}H_{30}O_6N_2, Br_2$, m. p. 164—166°, which

bishydrocotarnine methiodide,

$C_{26}H_{30}O_6N_2, MeI$, m. p. 151°, is decomposed by alcoholic sodium ethoxide yielding trimethylamine and *cotarnylidenehydrocotarnine* (annexed formula), m. p. 100—102° (decomp. 124°). *De-N-methylisobishydrocotarnine methiodide*, $C_{26}H_{30}O_6N_2, MeI$, m. p. 159—162°, reacts with silver oxide and water and subsequently with potassium hydroxide to form a substance called *bis-de-N-methyl-*

isobishydrocotarnine, $C_{26}H_{32}O_6N_2$, m. p. 218—220° (*hydriodide*, $C_{26}H_{30}O_6N_2, MeI$, m. p. 156—158°, decomp. 248°), the *methiodide*, $C_{26}H_{30}O_6N_2, MeI$, m. p. 156—158°, which is decomposed by sodium ethoxide, yielding trimethylamine and *cotarnylidene-de-N-methylhydrocotarnine* (see below). *Cotarnylidenehydrocotarnine* yields cotarnine by oxidation, and forms with methyl iodide a substance, $C_{26}H_{30}O_6N_2, MeI$, m. p. 115—117°, called *cotarnylidene-de-N-methylhydrocotarnine* (probable constitution annexed), which has pronounced basic properties (*hydriodide*, m. p. 209—211°, and yields by the evaporation of its solution in 50% alcohol the corresponding hydroxy-compound, *cotarnylidene-N-methylhydroxycotarnine*, $C_{26}H_{32}O_7N_2$, m. p. 73—75° (*methiodide*, m. p. 160—162°).

Bishydrocotarnine dimethiodide, by treatment with silver oxide and water, and subsequently with boiling potassium hydroxide, yields *bis-de-N-methylbishydrocotarnine*, $C_{26}H_{32}O_6N_2$, m. p. 118—120° (*hydrobromide*, m. p. 166—168° (*hydriodide*, m. p. 160—162°), the *methiodide*, m. p. 113—115°, of which yields trimethylamine and *cotarnylidene-de-N-methylhydrocotarnine* (annexed formula), m. p. 68—71° by treatment with alcoholic sodium ethoxide. The last-mentioned derivative does not react with methyl iodide.

A table is given showing the genetic relations of the preceding substances.

Alkaloids of Pareira Root. MAX SCHOLTZ (*Arch. Pharm.* 1911, 1909, 408—418. Compare *Abstr.*, 1896, i, 710; 1899, i, 92; 1907, i, 731).—It has been shown already (*loc. cit.*) that pareira root contains either *t.* or *d.* bebeerine. A second alkaloid, chondrodine, has now been isolated from the total alkaloids of the root, and this paper deals with the isolation and characterisation of this substance, which may be regarded provisionally as a hydroxybebeerine.

Chondrodine, $C_{15}H_{21}O_2N$, m. p. 218—220°, $[\alpha]_D^{20} = -75^\circ$ in alcohol, was obtained as an amorphous substance by a complicated process of separation from that portion of the total alkaloids which was insoluble both in ether and chloroform. The *hydrochloride*, $B.HCl$, m. p. 274—275°, crystallises in yellow leaflets; the *mercurichloride*, m. p. 284—290° (decomp.), is a crystalline powder; the *ferrichloride*, $B.HCl.FeCl_3$, m. p. 183—184°, occurs in microscopic crystals (!); the *perchlorate*, m. p. 232—233°, crystallises from hot water; the *picrate*, m. p. 193—194°, is a greenish-yellow, crystalline powder, and the *picrolonate*, m. p. 185—186°, forms greenish-yellow, stellate clusters of needles. The *methiodide*, m. p. 273° (decomp.), crystallises from water. The alkaloid contains a methoxyl and an NMe group. With acetic anhydride at 50—60° it furnishes an amorphous *diacetyl* derivative, which blackens above 270°. The *dibenzoyl* compound, m. p. 295°, separates from hot alcohol in crystalline granules. When heated with ethyl iodide in presence of alcohol and potassium hydroxide, chondrodine furnishes a *diethyl ether*, m. p. 205—207°, as a yellowish-white, sandy powder; the *hydrochloride* of this forms yellow needles and melts at 258°.

Bebeerine methiodide on further treatment with methyl iodide yields a *methyl ether*, $C_{16}H_{21}O(OMe)_2.NMe_2I$, m. p. 263—264°, which separates from water as a yellow, crystalline powder. *Ethyl bebeerine*, m. p. 150°, obtained by the action of ethyl iodide on bebeerine in presence of potassium hydroxide and alcohol, is a colourless powder, soluble in alcohol, but not in ether; it is levorotatory, $[\alpha]_D^{20} = -250^\circ$ in alcohol, gives a crystalline *hydrochloride*, yellow leaflets, m. p. 109—110°, and furnishes a *methiodide*, m. p. 255—256°, which crystallises from hot water in needles.

Brucine Polyhydrosulphides. ERNST SCHMIDT and D. BRUNS (*Reprint from Apoth. Zeit.*, 1911, No. 67).—Schmidt has shown already (this Journ., 1876, ii, 94) that when hydrogen sulphide is passed through a solution of brucine in alcohol, a yellow and a red polyhydrosulphide are formed, to which the formulae $B_2H_4S_6.2H_2O$ and $B_2.2H_4S_6$ were assigned respectively. Doehner subsequently prepared (*Abstr.*, 1895, i, 403) by the addition of ammonium polysulphide to brucine in alcohol, an orange-red polyhydrosulphide, to which he assigned the formula $B_2H_4S_6.2H_2O$. It is now shown that Doehner's compound is identical with Schmidt's red polyhydrosulphide.

T. A. H.

Dihydroterpenylamine. GEORGE FRANCIS MORRELL (*Ber.*, 1911, 44, 2560—2565).—When dihydrocarvylamine in dry ether is returned with hydrogen chloride, at first at 0° and finally without cooling, an unstable *dihydrochloride*, $C_{10}H_{19}NCl \cdot HCl$, white needles, m. p. 200°, is obtained. When this salt is heated with pyridine at 140—145°, it is converted into a substance, $C_{10}H_{19}N$, h. p. 96—100°/16 mm., $D_{20}^{25} 1.49284$ (*picrate*, m. p. about 176°), which is found to be a mixture of two stereoisomerides, α - and β -dihydroterpenylamine. Methods for their separation are indicated. α -Dihydroterpenylamine, h. p. 96—97°/15 mm., forms a benzoyl derivative, m. p. 219°, a suspension of which in glacial acetic acid is converted, by treatment with 10—15% ozone and subsequent heating on the water-bath, into acetone and a ketonic substance, $C_{14}H_{17}O_2N$, m. p. 183—185°, which is stated to be 2-benzoylamino-1-methylcyclohexan-4-one.

β -Dihydroterpenylamine, b. p. 100—101°/16 mm., forms more sparingly soluble salts than the α -base; the *nitrate*, m. p. 179° (decomp.), *picrate*, m. p. 195°, *hydrochloride*, m. p. 235° (decomp.), and *benzoyl derivative*, m. p. 178—179°, are described.

When a suspension of benzoyldihydrocarvylamine in acetic acid is ozonised and the product heated on the water-bath, a ketonic substance, $C_{14}H_{17}O_2N$, m. p. 218—219°, is obtained, which is regarded as 2-benzoylamino-4-acetyl-1-methylcyclohexane. C.S.

Action of Carbon Tetrabromide on Organic Bases. WILLIAM M. DEHN and ALBERT H. DEWEY (*J. Amer. Chem. Soc.*, 1911, 33, 1588—1598).—Carbon tetrabromide unites with organic bases to form molecular compounds, the best results being obtained by mixing solutions of the substances in dry ether. In order to explain the mechanism of formation of these compounds, it is suggested that a "coalescence" first takes place, due to the residual valencies of the nitrogen and bromine, thus $\begin{matrix} R \cdot NH_2 \\ | \\ Br \cdot CBr_3 \end{matrix}$, and that this is followed

by a shifting of the bonds, as shown by the formula $\begin{matrix} R \cdot NH_2 \\ | \\ Br \cdot CBr_3 \end{matrix} \rightarrow \begin{matrix} R \cdot NH_2 \\ | \\ Br_2C \cdot Br \end{matrix}$.

In the case of pyridine and piperidine, one molecule of the base unites with two molecules of carbon tetrabromide. It is evident that these two molecules are held with different degrees of tenacity, since vapour pressure curves indicate a dissociation of one molecule at 100°, and of the second molecule between 100° and 210°. Moreover, the complex compound is decomposed by water in accordance with the equation $C_5H_7N \cdot 2CBr_4 + 2H_2O \rightarrow CBr_4 + CO_2 + 3HBr + C_5H_7N \cdot HBr$. The

pyridine compound therefore has the structure: $\begin{matrix} C_5H_5N \cdot CBr_3 \\ | \\ Br \cdot Br \cdot CBr_3 \end{matrix}$ or $\begin{matrix} C_5H_5N \cdot Br \\ | \\ Br_2C \cdot Br \cdot Br \cdot CBr_3 \end{matrix} \rightarrow \begin{matrix} C_5H_5N \cdot Br \\ | \\ Br_2C \cdot Br \cdot CBr_2 \\ | \\ Br \end{matrix}$.

The *piperidine* compound, $C_6H_{11}N \cdot 2CBr_4$, m. p. 148°, crystallises in prismatic needles. The *pyridine* compound, $C_5H_5N \cdot 2CBr_4$, m. p. 218—220°, $D_{20}^{25} 1.70$, forms iridescent crystals, and is not decomposed

boiling alcohol. The quinoline compound, $C_8H_7N.CBr_4$, m. p. 42° , crystallises in white, prismatic needles. The 2-picoline compound, $C_8H_7N.2CBr_4$, m. p. 214° , forms large needles. With 6-lutidine, a product, m. p. 106° , was obtained in clusters of short needles; this may have been either the compound, $C_8H_5Me_2N.CBr_4$, or a mixture of the compound $C_8H_5Me_2N.2CBr_4$ with lutidine hydrobromide. Carbon tetrabromide reacts with phenylhydrazine with evolution of nitrogen and formation of bromoform and phenylhydrazine hydrobromide. On the addition of carbon tetrabromide to benzylamine, benzylamine hydrobromide separates. Diisocamylamine and dipropylamine yield products which are probably mixtures of the carbon tetrabromide compound with the hydrobromide of the base. With ethylamine, ethylamine hydrobromide, m. p. 157° , and the compound, $4NH_4Et.CBr_4$, m. p. 150° , are produced.

The following salts were obtained during the course of this work. Pyridine auribromide, m. p. 242° ; pyridine auribromide, m. p. 219° ; quinoline hydrobromide, m. p. $62-65^\circ$, and auribromide, m. p. 209° ; picoline auribromide, m. p. 209° ; 2:6-lutidine hydrobromide, m. p. 114° , and auribromide, m. p. 180° ; benzylamine auribromide, m. p. 175° ; and ethylamine auribromide, m. p. 190° . F. G.

Homologous Nature of Anthranil and Methylantranil. JOHANNES SCHEIDER (*Ber.*, 1911, 44, 2409-2418).—The question

whether anthranil, $C_6H_4 \begin{smallmatrix} \text{CO} \\ | \\ \text{NH} \end{smallmatrix}$ or $C_6H_4 \begin{smallmatrix} \text{CH} \\ | \\ \text{N} \end{smallmatrix} \text{O}$, and methylantranil,

$C_6H_4 \begin{smallmatrix} \text{CMe} \\ | \\ \text{N} \end{smallmatrix} \text{O}$, are homologous has very frequently been the

subject of discussion. It is shown by measurement of the ultra-violet absorption that the two compounds behave absolutely identically, and are therefore homologous.

Heller (*Abstr.*, 1908, i, 267; 1909, i, 832) has shown that anthranil and methylantranil behave differently towards 23% hydrochloric acid and sodium nitrite, but that they behave similarly when 39% acid is used. Measurements of the ultra-violet absorption of the two compounds in acids of these strengths show them to be identical in 4.9% acid, to differ in 24.5% acid, and to be identical again in 39% acid. Anthranil is shown to be very stable towards hydrogen chloride, and the change in absorption is not due to an opening of the ring. When kept for twelve days in 4.9% acid solution, anthranil gives slightly different curves; those for methylantranil correspond with the readings taken immediately on dissolution.

Anthroxanic acid, $C_6H_4 \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ | \\ \text{N} \end{smallmatrix} \text{O}$, likewise shows the same ultra-violet absorption as the two anthranils. The absorption in this case is not altered by solution in hydrochloric acid; possibly the alteration in the case of the homologous anthranils is due to salt formation.

E. F. A.

Constitution of the ψ -Bases of Quinoline. II. ADOLF KAUFMANN and J. M. PLÁ Y JANINI (*Ber.*, 1911, 44, 2670-2677).—Kaufmann and Strübin (this vol., i, 321) have recently obtained

experimental evidence in support of the view that the pseudo-bases (quinolanolis) of the quinoline series slowly undergo transformation into the isomeric α -alkylaminocinnamaldehydes, owing to the rupture of the pyridine ring. According to this view, 2-substituted quinoline bases should give rise to derivatives of cinnamic acid. The present paper contains an account of the reactions of 2-hydroxy-2-phenyl-1-methylquinoline (I) and its transformation into phenyl α -methylaminostyryl ketone (II):

2-Phenylquinoline methiodide (Doebner and Miller, Abstr., 1906, 721) is best prepared by the action of magnesium phenyl bromide on quinoline methiodide and subsequent oxidation of the resulting 2-phenyl-1-methyl-1:2-dihydroquinoline (compare Freund, Abstr., 1903, i, 156) with alcoholic iodine; its solution in water is colourless, in alcohol yellow, and in chloroform orange-red. When treated with aqueous sodium hydroxide, it yields the corresponding ψ -base (Decker and Fellenberg, Abstr., 1907, i, 1064), which is converted by the action of aqueous hydrochloric acid on its benzene solution into 2-phenylquinoline methochloride. This crystallises in long, almost colourless needles, which begin to decompose at 170°, and melt at 195–200° to a clear liquid; it is identical with the compound obtained by the interaction of silver chloride and 2-phenylquinoline methiodide. When treated with aniline and potassium hydroxide, the methiodide yields phenyl α -methylaminostyryl ketone anil,

which crystallises in greenish-yellow needles, melting at 141° to a green liquid. The anil is unstable, and readily decomposes when heated alone or in benzene solution, yielding a green dye. It is hydrolysed by cold mineral acids into its components; thus, with hydrochloric acid, it yields aniline and 2-phenylquinoline methochloride.

An alkaline suspension of the above-mentioned ψ -base is oxidised by exposure to air, or more rapidly by potassium ferricyanide, to ω -benzoyl- α -methylaminoacetophenone (III), which crystallises from benzene in stout needles, m. p. 123°. The latter compound dissolves in acids, yielding salts of 4-keto-2-phenyl-1-methyl-3:4-dihydroquinolium hydroxide (IV); the chloride, $\text{C}_{16}\text{H}_{15}\text{ONCl}$, crystallises as stellar aggregates of almost colourless needles, m. p. 237° (decomp.), the iodide is light yellow, m. p. 220°; the picrate, $\text{C}_{22}\text{H}_{16}\text{O}_8\text{N}_4$, forms yellow crystals, m. p. 180°. The salts are reconverted by the action of sodium carbonate or ammonia, or even by boiling with water, into ω -benzoyl- α -methylaminoacetophenone, as represented in the following scheme:

When heated at 250–260°, the chloride loses methyl chloride, yielding 4-hydroxy-2-phenylquinoline, m. p. 256° (Conrad and Limpach, Abstr.

1882, 505), which is transformed by distillation with zinc dust into 3-phenylquinoline, and by the action of phosphorus pentachloride into 4-chloro-3-phenylquinoline (Knorr and Fertig, Abstr., 1897, i, 371). An explanation is also given of the oxidation of 4-cyano-1-alkyl-2-hydroquinolines to 4-cyano-1-alkyl-2-quinolones, observed by Kaufmann and Albertini (Abstr., 1909, i, 958). It is assumed that the hydrogen in the 4-position is first oxidised to hydroxyl with the formation of the compound (V), which then undergoes transformation into (VI) by the addition of water and simultaneous rupture of the pyridine ring :

4-cyano-1-alkyl-2-quinolones are formed from this intermediate product by oxidation and loss of two molecules of water. The above-mentioned formation of α -benzoyl- α -methylaminoacetophenone may be explained in a similar manner. F. B.

Condensation Products of Isatic Acid and Hydroxythionaphthen, Indandione, and Indanone. EMILIO NOELTING and ALEX. HERZBAUM (*Ber.*, 1911, 44, 2585—2590).—Isatin in alkaline solution reacts with hydroxythionaphthen, indandione, or indanone just as with indoxyl (Noelting and Steuer, this vol., i, 165), yielding the following substances in accordance with the scheme :

where X = S, CO, or CH₂. Thus hydroxythionaphthen yields "thioquinolinecarboxylic acid," C₁₆H₉O₂NS, yellow needles, which decomposes above its m. p., about 335°, forming "thioquinoline," m. p. 172° (not 169°, *loc. cit.*). Indandione yields quinolylenephénylenesketonecarboxylic acid, C₁₇H₉O₃N, colourless needles, which is converted into the corresponding ketone (Noelting and Blum, Abstr., 1901, i, 728) above its m. p., about 340°. Indanone yields quinolylenephénylenemethanecarboxylic acid, C₁₇H₁₁O₃N, m. p. 330° (decomp), which is converted by fusion into quinolylenephénylenemethane (Noelting and Blum, *loc. cit.*); the latter has also been obtained by condensing indanone and α -aminobenzaldehyde in boiling dilute hydrochloric acid.

The sodium salts of the three preceding acids yield with metallic salts precipitates, the colours of which are tabulated. C. S.

[Preparation of Carbazole Derivatives.] KALLE & Co. (D.R.-P. 234336).—Carbazole derivatives obtained from 6-amino-1-naphthol-3-sulphonic acid and hydrazines have previously been described, and the reaction has now been extended to the case of 7-amino-1-naphthol-3-sulphonic acid.

The carbazole, 1-hydroxybenzo- β -naphthindole-3-sulphonic acid

(annexed formula), is prepared by heating this acid in aqueous solution with phenylhydrazine in the presence of sodium hydrogen sulphite and sodium hydroxide. On cooling, the carbazole separates in microcrystalline form.

The action is stated to be widely applicable, both with regard to the acid and hydrazine or other aromatic base employed.

The dyes obtained from tetrazotised benzidine, coupled with the foregoing carbazole (1 mol.) and salicylic acid and resorcinol respectively, are described in the original.

F. M. G. M.

Action of Hydroxylamine on Ketones of the Type $R \cdot CH:CH \cdot CH:CH \cdot C(=O)Ph$. ROBERTO CIUSA and A. TERNI (*Atti R. Accad. Lincei*, 1911, [v], 20, ii, 25—30. Compare Abstr. *Intern.*, 762; Ciusa and Bernardi, Abstr., 1910, i, 684).—The present paper is concerned with the further examination of α -cinnamylideneacetophenonehydroxylamineoxime, previously described.

Benzylidene- α -cinnamylideneacetophenonehydroxylamineoxime,

is obtained by boiling for one hour alcoholic solutions of benzaldehyde and the hydroxylamineoxime; it has m. p. 175°.

α -Cinnamylideneacetophenonehydroxylamineoxime, when oxidised with permanganate, yields benzoic acid and a 3-phenyl-5-styryl-oxazole, $CHPh:CH \cdot C \begin{matrix} CH \cdot CPh \\ \searrow \quad \nearrow \\ O \quad N \end{matrix}$, which forms lustrous scales, m. p.

138°. The hydroxylamineoxime yields with nitrous acid (sodium nitrite and glacial acetic acid in the cold) an isomeride of α -cinnamylideneacetophenoneoxime, m. p. 124°, identical with the substance previously obtained among the secondary products of the reaction between cinnamylideneacetophenone and hydroxylamine (compare Ciusa and Terni, *loc. cit.*). To this substance the constitution of a

3-phenyl-5-styryldihydroisooxazole, $CHPh:CH \cdot CH \begin{matrix} CH_2 \cdot CPh \\ \searrow \quad \nearrow \\ O \quad N \end{matrix}$, is ascribed.

It yields a dibromo-derivative, $C_{17}H_{15}ONBr_2$, which crystallises in small, colourless needles, m. p. 145°. When α -cinnamylideneacetophenonehydroxylamineoxime is boiled with 90% acetic acid or normal hydrochloric acid, it gives the α -oxime of m. p. 135°. This explains the fact that when hydroxylamine hydrochloride reacts with unsaturated ketones in the absence of sodium acetate only oximes, and not hydroxylamineoximes, are obtained (compare Ciusa and Bernardi, *loc. cit.*).

R. V. S.

Aromatic ψ -Thiocarbamides and their Conversion into Aryl ortho-Thiocarbonates. FRITZ ARNDT (*Annalen*, 1911, 384, 322—351).

—The interaction of *p*-tolyl mercaptan and cyanamide, with the addition of ether to moderate the violence of the reaction, gives an almost quantitative yield of *p*-tolyl- ψ -thiocarbamide,

m. p. 110° (decomp.). The substance decomposes when heated alone

or in boiling alcohol, yielding *p*-tolyl mercaptan and dicyanodiamide. It forms a *dibenzonate*, $\text{NBz}_2\text{C}(\text{NHBz})\cdot\text{S}\cdot\text{O}_2\text{H}_7$, m. p. 132–133°, with benzoyl chloride in cold pyridine, and also yields well crystallised salts, of which the *acetate*, *sulphate*, *chromate*, *chloride*, and *nitrate*, m. p. 173°, are described. Very characteristic is its behaviour in the presence of nitric and sulphuric acids, whereby a *nitrate-sulphate*,

is obtained, even when the dilution of the nitric acid is one in 100,000; provided an excess of the reagent is present, this salt is so insoluble that it can be employed for the estimation of nitrates. Similar, sparingly soluble double salts are obtained in the presence of sulphuric acid and the majority of the monobasic acids or hydroferrocyanic acid, but not hydroferricyanic acid, hydrogen cyanide, phosphoric acid, or organic acids; however, the place of the sulphuric acid cannot be taken by any other acid. (The isomeric benzyl- ψ -thiocarbamide does not form double salts corresponding with the preceding.)

p-Tolyl- ψ -thiocarbamide chloride or acetate reacts with concentrated sodium nitrate (not potassium nitrite) in neutral solution to form the *nitrite*, m. p. 112°, but in the presence of hydrochloric acid, *nitroso-p-tolyl- ψ -thiocarbamide*, $\text{C}_7\text{H}_7\text{ON}_2\text{S}$, decomp. 112°, is obtained, which receives the constitution $\text{C}_7\text{H}_7\text{S}\cdot\text{C}(\text{NH})\cdot\text{NH}\cdot\text{NO}$ or

on account of its absence of colour, insolubility in dilute acids, response to the Liebermann test, and conversion by glacial acetic acid into nitrogen and *p*-tolyl thiocyanate. When the nitroso-compound is recrystallised from methyl alcohol without the addition of a little ammonia, it is partly converted into a yellow *substance*, decomp. about 130°, which is probably $\text{C}_7\text{H}_7\text{S}\cdot\text{CO}\cdot\text{NH}\cdot\text{NO}$.

When its methyl-alcoholic solution is warmed with aqueous ammonia, nitroso-*p*-tolyl- ψ -thiocarbamide is converted into *p-tolyl orthothiocarbonate*, $\text{C}(\text{S}\cdot\text{C}_7\text{H}_7)_2$, needles, m. p. 147°, which forms with bromine in chloroform an unstable *perbromide*, $\text{C}(\text{S}\cdot\text{C}_7\text{H}_7)_2\cdot\text{Br}_2$, dark red leaflets, m. p. below 100° (of freshly prepared specimen), which readily changes to a yellow, crystalline *tetrabromide*, $\text{C}(\text{S}\cdot\text{C}_7\text{H}_7)_2\cdot\text{Br}_4$, m. p. 169°. By boiling the tetrabromide with alcohol or warming the thiocarbonate itself with acetic and a little concentrated sulphuric acid, the *disulphoxide*, $\text{C}(\text{S}\cdot\text{C}_7\text{H}_7)_2(\text{SO}\cdot\text{C}_7\text{H}_7)_2$, m. p. 92°, is obtained. An attempt to synthesise *p*-tolyl orthothiocarbonate from sodium *p*-tolylmercaptide and carbon tetrachloride in boiling alcohol resulted in the formation of *p-tolyl orthothioformate*, $\text{CH}(\text{S}\cdot\text{C}_7\text{H}_7)_3$, m. p. 111°, which is also produced by the reduction of the orthothiocarbonate by zinc and acetic acid.

Benzyl- ψ -thiocarbamide and sodium nitrite react in acid solution to form a stable *nitrite*, m. p. 126° (decomp.), which yields benzyl disulphide by heating; a substance corresponding with nitroso-*p*-tolyl- ψ -thiocarbamide is not formed.

p-Tolyl mercaptan and phenylcyanamide react in ether to form *phenyl-p-tolyl- ψ -thiocarbamide*, $\text{NHPh}\cdot\text{C}(\text{NH})\cdot\text{S}\cdot\text{C}_7\text{H}_7$, m. p. 148°, which forms a *hydrochloride*, *nitrate*, m. p. 132°, and *benzoyl derivative*, m. p. 151.5°, and is easily methylated, yielding *phenyl-p-tolylmethyl- ψ -thiocarbamide*, $\text{NPhMe}\cdot\text{C}(\text{NH})\cdot\text{S}\cdot\text{C}_7\text{H}_7$, m. p. 121°.

Diphenyl-p-tolyl- θ -thiocarbamide, $\text{NHPh}\cdot\text{C}(\text{NPh})\cdot\text{S}\cdot\text{C}_6\text{H}_4$, m. p. 119—120°, is obtained by desulphurising diphenylthiocarbamide in benzene by mercuric oxide and treating the resulting solution of carbodiphenylimide with *p*-tolyl mercaptan.

Hofmann's triphenylisomelamine, m. p. 185° (Abstr., 1886, 233), is shown to be an additive compound of triphenylmelamine and phenyleyanamide; the former constituent can be removed by dilute acid or boiling water. C. S.

Conversion of Nitroaldehydes into Cyanoaldehydes. GIACOMO PONZIO (*Gazzetta*, 1911, 41, i, 787—793. Compare Ponzio and Giovetti, Abstr., 1910, i, 194).—The author has shown previously that an aliphatic nitro-group may be substituted by $-\text{NH}_2$ or $-\text{NHPh}$ (compare Abstr., 1910, i, 339, 442, 699), and he now finds that it may also be replaced by $-\text{CN}$. A new method of preparation is thus provided for the hydrazones of ω -cyanobenzaldehyde, which, although longer than that formerly given, has the advantage that the *o*- and *m*-substituted phenylhydrazones can also be obtained.

ω -Cyanobenzaldehyde-*o*-nitrophenylhydrazone (*loc. cit.*) is the only substance produced when ω -nitrobenzaldehyde-*o*-nitrophenylhydrazone is boiled for two hours in aqueous alcoholic solution with potassium cyanide.

ω -Cyanobenzaldehyde-*m*-nitrophenylhydrazone,
 $\text{CN}\cdot\text{CPh}\cdot\text{N}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$,

which cannot be obtained by the method formerly given, crystallises in small, yellow prisms, m. p. 197—198°. It is soluble in alkali to which a drop of alcohol has been added, and it gives a yellow coloration. The ω -nitrobenzaldehyde-*m*-nitrophenylhydrazone employed for its preparation is obtained by heating the sodium salt of ω -nitrotolene with *m*-nitrobenzenediazonium sulphate; it crystallises in small, brick-red prisms, m. p. 132° (decomp.).

ω -Cyanobenzaldehyde-*p*-nitrophenylhydrazone, ω -cyanobenzaldehyde-*o*-chloro-*p*-nitrophenylhydrazone, and ω -cyanobenzaldehyde-*o*-*p*-dinitrophenylhydrazone can also be prepared by the new method. The ω -nitrobenzaldehyde-*o*-*p*-dinitrophenylhydrazone necessary for the preparation of the last-named substance is obtained by diazotising 2,4-dinitroaniline and acting on the sodium salt of ω -nitrotolene with the 2,4-dinitrobenzenediazonium sulphate so produced. The substance crystallises in yellowish-brown, flat needles, m. p. 152° (decomp.). R. V. S.

Syntheses of Pyrazolones from a Derivative of γ -Pyrone.

F. CARLO PALAZZO and RAFFAELE LIVERANI (*Atti R. Accad. Lincei*, 1911, [v], 20, ii, 55—60. Compare Palazzo, Abstr., 1906, i, 701).—By the action of hydrazine hydrate on ethyl dimethylpyronecarboxylate the authors have obtained three different nitrogenous compounds, which all belong to the pyrazolone group. When 1 mol of hydrazine hydrate is boiled with the ester in methyl-alcoholic solution for two minutes, a small quantity (2%) of a compound is obtained, which crystallises in minute needles, m. p. 195—196°, and gives a reddish-violet coloration with ferric chloride. Of this substance

no analysis could be made, but it is identical with the product $2\text{H}_{10}\text{O}_4\text{N}_2$ from hydrazine hydrate and ethyl acetylmalonate, which is known to be 3-methyl-5-pyrazolone-4-carboxylate. When two mol. of hydrazine hydrate are heated in a sealed tube with a concentrated methyl-alcoholic solution of ethyl dimethylpyrnedicarboxylate for some hours at 120° , a substance, $\text{C}_8\text{H}_{10}\text{O}_4\text{N}_2 \cdot \text{OEt}$, is obtained in good yield. The compound has m. p. $125\text{--}130^\circ$ (softening considerably at $40\text{--}60^\circ$), and gives a reddish-brown coloration with ferric chloride. It is suggested that it may be an isomeric of the first-mentioned compound. By the interaction of two mols. of hydrazine hydrate and ethyl dimethylpyrnedicarboxylate in methyl-alcoholic solution as before, the mixture being boiled for two hours, a substance is produced, which has m. p. $142\text{--}145^\circ$. It gives a reddish-brown coloration with ferric chloride. The analytical results agree with the formula $\text{C}_{11}\text{H}_{14}\text{O}_4\text{N}_4$, but the substance appears to be a mixture, possibly of equimolecular amounts of the two pyrazolones, $\text{C}_7\text{H}_{10}\text{O}_4\text{N}_2$ and $\text{C}_8\text{H}_{10}\text{O}_4\text{N}_2$. R. V. S.

The Pyrazoline Transformation of Unsaturated Hydrazones.
HUGO BAUER and HEDWIG DIETERLE (*Ber.*, 1911, 44, 2697—2702).—It has been shown by Auwers (*Abstr.*, 1909, i, 59; 1910, i, 70) that the phenylhydrazones of many unsaturated ketones may be transformed into pyrazoline derivatives by heating them with glacial acetic acid. That the reaction is, however, not a general one has been confirmed by the authors from an examination of the behaviour of unsaturated ketones of the type $\text{CHPh}:\text{CH}:\text{CH}:\text{CH}:\text{CO}:\text{CH}:\text{CHR}$. When $\text{R} = \text{anisy}$ or furyl, the action of phenylhydrazine leads directly to the formation of a pyrazoline derivative; the immediately formed phenylhydrazones could not be isolated. On the other hand, when $\text{R} = \text{phenyl}$, the phenylhydrazone is not converted into a pyrazoline derivative, even by prolonged heating with acetic acid.

1-Phenyl-3- β -styrylovinyl-5-anisylpyrazoline,

prepared by heating anisylidencinnamylideneacetone [p -methoxystyryl β -styrylovinyl ketone] with phenylhydrazine in glacial acetic acid solution, forms yellow crystals, m. p. $155\text{--}156^\circ$; its alcoholic solution has an intense, green fluorescence. When oxidised with aqueous potassium permanganate, it yields benzoic acid and 1-phenyl-5-anisylpyrazole-3-carboxylic acid, $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{C} \begin{array}{c} \text{CH} \\ \text{NPh} \cdot \text{N} \end{array} > \text{C} \cdot \text{CO}_2\text{H}$, which crystallises from water in white needles, m. p. $178\text{--}179^\circ$, and yields a copper salt, $(\text{C}_{11}\text{H}_{12}\text{O}_3\text{N}_2)_2\text{Cu}$, crystallising in slender, green needles. The formation of this acid proves that the double linking, adjacent to the anisyl group, is concerned in the pyrazoline formation, and this is confirmed by the behaviour of the two following phenylhydrazones, which do not contain a double linking in this position, and, therefore, are not transformed into pyrazoline derivatives.

{ Bromo- η -methoxy- α -phenyl- η -anisyl- Δ^4 -heptadien-1-onephenylhydrazone, $\text{CHPh}:\text{CH}:\text{CH}:\text{CH}:\text{C}(\text{N} \cdot \text{NHPh}) \cdot \text{CHBr} \cdot \text{CH}(\text{OMe}) \cdot \text{C}_6\text{H}_4 \cdot \text{OMe}$,

obtained from the corresponding ketone (this vol., i, 881) and phenylhydrazine, has m. p. 201—202.5°.

$\gamma\delta\epsilon$ -Tribromo- η -methoxy- α -phenyl- η -anisyl- Δ^2 -hepten- ϵ -onephenylhydrazones, $\text{CHPh}\cdot\text{CH}\cdot[\text{CHBr}]_3\cdot\text{C}(\text{N}\cdot\text{NHPh})\cdot\text{CHBr}\cdot\text{CH}(\text{OMe})\cdot\text{C}_6\text{H}_5$, also prepared from the corresponding ketone (*loc. cit.*), forms slender, yellow needles, m. p. 181—182°.

Styryl β -styrylvinyl ketonephenylhydrazones,

prepared from its components in alcoholic solution, crystallises as yellowish-brown platelets, m. p. 111—112°.

Furfurylideneacinnamylideneacetone [β -styryl- β' -furyldiviny] ketone,

obtained by the condensation of furfuraldehyde with cinnamylideneacetone (β -styrylvinyl methyl ketone) by means of sodium hydride in aqueous alcoholic solution, crystallises in lustrous, golden yellow leaflets, m. p. 97—98°. It gives an intense red coloration with strong nitric acid, and is transformed by the action of phenylhydrazine into 1-phenyl-3- β -styrylvinyl-5-furylpyrazoline,

which crystallises in strongly fluorescent, slender, yellow needles, m. p. 165—166°, and is oxidised by aqueous permanganate to benzoyl acid and 1-phenylpyrazole 3:4-dicarboxylic acid, m. p. 250—255°.

F. E.

Hydantoins. IV. 2-Thio-1-phenylhydantoins from Some α -Amino-acids. CHARLES A. BRAUTLECHT (*J. Biol. Chem.*, 1911, 10, 139—146. Compare Wheeler and Brautleht, this vol., i, 509.). The action of phenylthiocarbimide on a number of α -amino acids has been studied. In the presence of alkali, interaction takes place with the formation of alkali salts of thiohydantoic acids. These readily undergo transformation into the corresponding hydantoins on treatment with hydrochloric acid. Crystalline thiophenylhydantoins could not, however, be obtained from cystine and α -pyrrolidonecarboxylic acid.

These thiophenylhydantoins are characteristic of the α -amino-acids, and should serve for their identification. When warmed with potassium hydroxide, they are hydrolysed to the potassium salts of the thiohydantoic acids. They are desulphurised by digestion in aqueous or dilute alcoholic solutions with silver nitrate, mercuric chloride, etc., and are stable in the presence of boiling hydrochloric acid.

2-Thio-1-phenylhydantoin, $\text{CS}\begin{matrix} \text{NPh}\cdot\text{CO} \\ \text{NH}\cdot\text{CH}_2 \end{matrix}$, from glycine has m. p. 240—242°.

2-Thio-1-phenyl-4-ethylhydantoin from α -amino- n -butyric acid crystallises in plates, m. p. 190—192°.

2-Thio-1-phenyl-4-isopropylhydantoin, obtained from valine, forms colourless needles, m. p. 206—208°.

2-Thio-1-phenyl-4-benzylhydantoin from phenylalanine separates as colourless prisms, m. p. 187°.

Tyrosine gives rise to 3-thio-1-phenyl-4-p-hydroxybenzylhydantoin, colourless or straw-coloured prisms, m. p. 214—216°.
 From asparagine 3-thio-1-phenylhydantoin-4-acetamide is obtained; it crystallises in colourless, lenticular prisms, m. p. 234°.
 The potassium salt of the hydantoic acid,

$$\text{NHPh}\cdot\text{CS}\cdot\text{NH}\cdot\text{CH}(\text{CO}_2\text{K})\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}_2$$
 separates in colourless plates, m. p. 154°.

2-Thio-1-phenylhydantoin-4-acetic acid, $\begin{matrix} \text{NPh}\cdot\text{CO} \\ \text{CS}\cdot\text{NH} \end{matrix} > \text{CH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, from aspartic acid crystallises in colourless prisms, m. p. 233—234° (decomp.).

2-Thio-1-phenylhydantoin-4-propionic acid, prepared from glutamic acid, separates in microscopic needles, m. p. 169—170°. E. F. A.

Hydantoins. V. Synthesis of 3:5-Dichlorotyrosine.
 HENRY L. WHEELER, CHARLES HOFFMAN, and TREAT B. JOHNSON (*J. Biol. Chem.*, 1911, 10, 147—157).—Tyrosine itself does not react smoothly with chlorine, but tyrosinehydantoin reacts with chlorine in glacial acetic acid solution, forming the corresponding hydantoin of 3:5-dichlorotyrosine. The same compound was obtained on reducing 3:5-dichlorobenzylidenehydantoin with hydriodic acid, a compound which was prepared by Wheeler and Hoffmann (this vol., i, 498) by condensation of hydantoin with 3:5-dichlorobenzaldehyde. Chlorine therefore is substituted in the same positions (3:5) in the benzene nucleus of tyrosinehydantoin as are taken by iodine and bromine when they combine with tyrosine. On digestion with barium hydroxide, the hydantoin is converted into 3:5-dichlorotyrosine. This crystallises with 2H₂O, dissociates in aqueous solution, and reacts acid to litmus; it does not give a red coloration with Millon's reagent.

Benzylidenehydantoin reacts with chlorine and bromine in acetic acid, forming α -chloro- and α -bromo-benzylidenehydantoin respectively. The latter is reduced by hydriodic acid, forming benzylhydantoin. Anisylidenehydantoin was not reduced under practically the same conditions.

3:5-Dichlorotyrosinehydantoin crystallises in rhombohedral prisms, m. p. 202° (decomp.).

3:5-Dichlorotyrosine separates in rectangular, prismatic crystals, m. p. 252° (decomp.). The hydrochloride forms large, prismatic, colourless crystals, m. p. 260—265° (decomp.).

α -Bromobenzylidenehydantoin, $\begin{matrix} \text{NH}\cdot\text{CO} \\ \text{CO}\cdot\text{NH} \end{matrix} > \text{C}\cdot\text{CBrPh}$, crystallises in plates, m. p. 240° to an oil.

α -Thiobenzylidenehydantoin, prepared by boiling the bromo-compound with potassium hydrosulphide, crystallises in yellow prisms, m. p. 199° (decomp.).

α -Chlorobenzylidenehydantoin also crystallises in plates, m. p. 273° to an oil.

α -Methoxybenzylhydantoin, prepared by reduction of anisylidenehydantoin (Wheeler and Hoffman, *loc. cit.*), crystallises in yellow, hexagonal tablets, m. p. 174° to a clear oil. Anisylidenehydantoin could not be reduced with tin and hydrochloric acid; after boiling

with zinc and acetic acid, it was recovered unchanged, but in a colourless form. Digestion with sodium hydroxide converts it into *p*-methoxyphenylpyruvic acid.

R. P. A.

Pyrimidines. LIII. Condensation of Ethyl Formate and Ethyl Oxalate with Some Pyrimidinethioglycolates. THOMAS B. JOHNSON and NORMAN A. SHEPARD (*Amer. Chem. J.*, 1911, 43, 345—361).—The work described was undertaken with the object of obtaining further knowledge of the behaviour of the group $-\text{S}\cdot\text{CH}_2\cdot\text{CO}-$. Johnson and Guest (*Abstr.*, 1909, i, 744) have studied the condensation of ethyl formate with ethyl benzylthiolacetate, and Hinsberg (*Abstr.*, 1910, i, 334) has shown that the methylene group in ethyl thiodiglycolate react readily with α -dicarbonyl compounds.

The only pyrimidine derivative of ethyl thiolacetate hitherto described is ethyl 1:6-dihydro-6-pyrimidone-2-thiolacetate, which was obtained by Wheeler and Liddle (*Abstr.*, 1909, i, 61) by the action of ethyl chloroacetate on 2-thiouracil. It is now shown that trans-*thiocarbaminoacrylic acid*, $\text{NH}_2\cdot\text{CS}\cdot\text{NH}\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$, which forms lustrous plates and does not melt below 300° , is also produced in this reaction.

Ethyl 1:6-dihydro-6-pyrimidone-2-thiolacetate condenses with ethyl formate in presence of sodium ethoxide with formation of ethyl 1:6-dihydro-6-pyrimidone-2- α -thiol- β -hydroxyacrylate,

m. p. $138-140^\circ$, which crystallises in prisms.

By the condensation of ethyl oxalate with 1:6-dihydro-6-pyrimidone-2-thiolacetate, diethyl 1:6-dihydro-6-pyrimidone-2-thioloxalylacetate

which crystallises in stout blocks, and is decomposed by hydrochloric acid with formation of 1:6-dihydro-6-pyrimidone-2-thiolpyruvic acid,

also decomposed by potassium hydroxide with production of uracil.

When ethyl 1:6-dihydro-6-pyrimidone-2- α -thiol- β -hydroxyacrylate is heated with thiocarbamide in presence of sodium ethoxide, 2-thio-4-hydro-2'-thio-6'-pyrimidinethiol-1:6-dihydro-6-pyrimidone,

is produced, which crystallises in needles and decomposes at $285-295^\circ$.

Thiocarbamide also condenses with ethyl 1:6-dihydro-6-pyrimidone-2-thioloxalylacetate with formation of small quantities of a compound which is probably identical with that just described.

Ethyl 4-methyl-1:6-dihydro-6-pyrimidone-2-thiolacetate,

m. p. $145-146^\circ$, obtained by the action of ethyl chloroacetate on 2-thio-4-methyluracil, forms colourless needles; the corresponding acid

m. p. $192-197^\circ$ (decomp.), crystallises in colourless prisms; a potassium salt is described.

When ethyl 4-methyl-1:6-dihydro-6-pyrimidone-2-thiolacetate is heated with ethyl formate in presence of sodium ethoxide, ethyl methyl-1:6-dihydro-6-pyrimidone-2- α -thiol- β -hydroxyacrylate,

p. 106—108², is produced, which forms colourless crystals; an attempt to reduce this compound with sodium amalgam resulted in the formation of 4-methyl-1:6-dihydro-6-pyrimidone-2-thiolacetic acid. The condensation of thiocarbamide with ethyl 4-methyl-1:6-dihydro-pyrimidone 2- α -thiol- β -hydroxyacrylate, 4-methyl-2(tetrahydro-2'-thio-pyrimidinethiol)-1:6-dihydro-6-pyrimidone,

is produced, which forms clusters of prisms, and does not melt below 65°.

Ethyl 4-methyl-1:6-dihydro-6-pyrimidone-2-thiolacrylate,

p. 139—140², obtained by the action of ethyl oxalate on ethyl methyl-1:6-dihydro-6-pyrimidone-2-thiolacetate, crystallises in stout, colourless blocks; it condenses with thiocarbamide with formation of compound,

p. 164—165², which crystallises in hexagonal tablets.

E. G.

Preparation of Halogenated Derivatives of Indigotin.

BAISCHE ANILIN- & SODA-FABRIK (D.R.P. 234961).—When 4:4'-dichloroindigotin is suspended in nitrobenzene (or other indifferent liquids), cooled, and treated with chlorine, further halogenation takes place, yielding tri- and tetra-chloro-derivatives. The corresponding azo-derivatives are obtained when the substance is suspended in dilute sulphuric acid and treated with bromine at a temperature below 5°.

F. M. G. M.

[Preparation of Methylindanthren.] FARBENFABRIKEN VORM.

FRIEDR. BAYER & CO. (D.R.-P.

234294).—Methylindanthren (an-

nexed formula), dark blue needles

with metallic lustre, is prepared

by boiling 2-bromo-1-aminoanthra-

quinone with 2-bromo-1-methyl-

aminoanthraquinone in the presence

of sodium acetate and cupric chloride

in naphthalene solution; it dissolves with a yellowish-brown colour in concentrated sulphuric acid.

F. M. G. M.

Action of Nitrous Acid on Substituted Hydrazidines.

GIACOMO PONZIO and C. GASTALDI (*Gazzetta*, 1911, 41, i, 793—796).—

The substituted hydrazidines previously described (compare Ponzio, *Abstr.*, 1910, i, 443, 699) when treated with nitrous acid do not yield

VOL. C. i.

tetrazoles, but, instead, the hydrogen of the imino-group is displaced by $-\text{NO}$, so that ω -aminobenzaldehyde-*p*-nitrophenylhydrazone,

yields ω -aminobenzaldehydenitroso-*p*-nitrophenylhydrazone,

This nitroso-compound is insoluble in alkali hydroxides, and when boiled with water gives ω -aminobenzaldehyde-*p*-nitrophenylhydrazone and benzoyl-*p*-nitrophenylhydrazine, $\text{COPh} \cdot \text{NH} \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2$.

ω -Aminobenzaldehydenitroso-*p*-nitrophenylhydrazone forms small yellow laminae, m. p. 127° (decomp.). It gives an emerald-green coloration with concentrated sulphuric acid and phenol. R. V. S.

Preparation of Secondary 4-Dimethylamino-1-phenyl-2:3-dimethyl-5-pyrazolone Citrate. RUDOLF ORRO (D.R.-P. 234631).—Two salts of this base with citric acid have previously been described, and the "citrovantille" employed in pharmacy consists of mixtures of both in varying proportions. The primary salt (a syrup) is prepared from equal molecular proportions of the base and acid, the tertiary, containing 3 mols. of the base, has similar properties, while the secondary, 4-dimethylamino-1-phenyl-2:3-dimethyl-5-pyrazolone citrate, $\text{C}_6\text{H}_8\text{O}_7(\text{C}_{12}\text{H}_{17}\text{ON}_2)_2$, has now been prepared by allowing the requisite proportions of the components to react either in warm aqueous solution at 75° or in a fusion without solvent; it crystallises from hot water. F. M. G. M.

Isomeride of apoSafranine and the Third Isomeride of Phenosafranine. FRIEDRICH KEHRMANN and JOSÉ RIERA Y PARRA (Ber., 1911, 44, 2622—2627).—2:4:6:5'-Tetra-nitro-2'-aminodiphenylamine, $\text{C}_6\text{H}_2(\text{NO}_2)_4 \cdot \text{NH} \cdot \text{C}_6\text{H}_3(\text{NO}_2)_2 \cdot \text{NHPh}$, brownish-yellow crystals, decomp. above 174° , obtained by warming equal molecular quantities of picryl chloride and 4-nitro-2-aminodiphenylamine in alcoholic solution, is converted in alcoholic suspension by concentrated sodium hydroxide into 1:3:7-trinitro-10-phenyldihydrophenazine,

blackish-violet needles, decomp. above 265° , which dissolves in hot alcoholic sodium hydroxide with a violet colour. When suspended in glacial acetic acid and reduced by stannous chloride and hydrochloric acid, it is reduced to the triamino-phenyldihydrophenazine (isolated as the yellow stannichloride), which loses ammonia by careful warming in faintly alcoholic solution, the subsequent addition of sodium chloride precipitating 2:6-diamino-10-

This salt forms blackish-violet, prismatic crystals with a bronze lustre, yields a violet-blue aqueous solution (so also do other mono-acidic salts), a brown solution in slightly fuming sulphuric acid, and a greenish-blue solution in concentrated sulphuric acid, which changes to magenta-red and finally to violet-blue on sufficient dilution with water; these colour changes indicate the existence of four series of salts, as is the case with phenosafranine itself. This new isophenosafranine dyes tanned cotton a dirty greenish-blue, the

colour changing to red by treatment with dilute hydrochloric acid, and by washing to a blue which is fast to alkalis and soap.

iso-Phenosafranine chloride and acetic anhydride at the ordinary temperature yield an *acetyl* derivative,

reddish-brown needles, from which by the elimination of the amino-group is obtained the *acetyl* derivative of *iso*-aposafranine chloride,

the corresponding *nitrate*, *ferrichloride*, and *platinichloride* are mentioned. *iso*-apoSafranine chloride, obtained by hydrolysing the preceding *acetyl* derivative, is an almost black, crystalline powder, which is unstable in solution; the *platinichloride*, $2\text{C}_6\text{H}_3\text{N}_2\text{PtCl}_6$, is a black, crystalline powder.

iso-Phenosafranine chloride and acetic anhydride and sodium acetate on the water-bath yield the *diacetyl* derivative,

brownish-red crystals with a bronze lustre; the *platinichloride* is a brownish-red, crystalline substance. C. S.

Third Isomeride of apoSafranine. FRIEDRICH KEHRMANN and A. MASSLENIKOFF (*Ber.*, 1911, 44, 2628—2631. Compare preceding abstract).—When the green *isophenosafranine* chloride (1:3-diamino-10-phenylphenazonium chloride) undergoes prolonged treatment at the ordinary temperature with acetic anhydride and acetic acid, it is converted into 3-amino-1-acetyl-amino-10-phenylphenazonium chloride,

dichromate, *aurichloride*, and *iodide* are described), from which 1-amino-10-phenylphenazonium salts are obtained by elimination of the amino-group and subsequent hydrolysis; the *nitrate*, *bromide*, *platinichloride*, *dichromate*, *iodide*, and *aurichloride* are described. The *acetyl* derivative, which is prepared best from the bromide, is obtained in small, chocolate-brown crystals, and forms a dark brown, crystalline *platinichloride*. C. S.

Synthesis of Naphthaphenazine Derivatives. FRIEDRICH KEHRMANN and JOSÉ RIERA Y PUNTI (*Ber.*, 1911, 44, 2618—2621).—

obtained by reducing picryl- β -naphthylamine with the calculated amount of stannous chloride in boiling alcohol and concentrated hydrochloric acid, is purified best by means of the *diacetyl* derivative, yellow leaflets, m. p. 340° (decomp.), and forms red crystals which sublime at 320° with partial decomposition. Its *diacetyl* derivative does not form an azonium compound with methyl sulphate.

1:3-Diaminonaphthaphenazine, obtained in a similar manner from picryl- α -naphthylamine, forms dark red crystals and sublimes at 290—300° (decomp.). The *diacetyl* derivative, yellow needles, m. p. 320° (decomp.), easily combines with methyl sulphate in nitrobenzene

at 150°, yielding after hydrolysis with concentrated hydrochloric acid, 1 : 3-diaminomethyl-naphthaphenazonium chloride,

dark red needles; the *platinichloride*, $2\text{C}_{17}\text{H}_{15}\text{N}_4\cdot\text{PtCl}_6$, is described. C. S.

Preparation of Iminoalkyl Derivatives of Azimino-toluidides. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (Bk. P. 234966).—*Acetylaziminoaceto-o-toluidide* (annexed formula), m. p.

222—224°, was prepared by the reduction (iron and acetic acid) and subsequent diazotisation of 5-nitro-diacetyl-*m*-tolylendiamine; the acetyl group in the azimino-ring was then eliminated by boiling with sodium hydroxide, yielding on acidification 4 : 5-azimino-2-*aceto-o-toluidide*, a colourless powder, m. p. 235—237°; this was converted into its *benzyl* derivative, the remaining acetyl group removed by heating with sulphuric acid, and the resulting 4 : 5-*benzylazimino-o-toluidide* (annexed formula) precipitated with an alkali hydroxide; it forms a crystalline powder, m. p. 161—163°.

Other alkyl derivatives of this base can be readily prepared in a similar manner. F. M. G. M.

Diguanides. GEORG CONN (*J. pr. Chem.*, 1911, [ii], 84, 394—406).—Diguanides of the type $\text{NH}\cdot\text{C}(\text{NHR})\cdot\text{NH}\cdot\text{C}(\text{NH}_2)_2\cdot\text{NH}$, where R = aryl, are readily obtained in the form of their hydrochlorides by heating dicyanodiamide with the hydrochlorides of aromatic amines in aqueous solution.

Phenyldiguanide (Lumière and Perrin, *Abstr.*, 1905, i, 249), prepared from aniline hydrochloride and dicyanodiamide, forms a *picrate*, crystallising in yellow needles, m. p. 176—179°, with previous sintering.

m-Nitrophenyldiguanide, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{C}_2\text{H}_6\text{N}_6$, obtained from *m*-nitroaniline, forms amber-yellow prisms or rhombic leaflets, m. p. 147—148°, it crystallises with alcohol in transparent prisms having a colour resembling that of potassium dichromate; it forms a yellow *hydrochloride* and a *picrate*, m. p. 210—211°.

p-Hydroxyphenyldiguanide, $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{C}_2\text{H}_6\text{N}_6$, prepared from *p*-aminophenol hydrochloride, crystallises in spherical aggregates of long, white needles, which become brown at 200° and have m. p. 211°; the hydrochloride has m. p. 203° (compare *loc. cit.*); the *picrate*, m. p. 205—206°, with previous sintering at 203°; when heated with acetic anhydride and sodium acetate, it yields a substance, m. p. 236—237°, which is considered to be an acetyl derivative of the compound $\text{NH}\cdot\text{C} \begin{array}{c} \text{---} \text{NH}\cdot\text{C}(\text{NH}) \text{---} \\ \text{---} \text{N} \text{---} \text{CMe} \end{array} \text{N}\cdot\text{C}_6\text{H}_4\cdot\text{OH}$.

p-Phenyldiguanide, $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{C}_2\text{H}_6\text{N}_6$, crystallises in colourless leaflets, m. p. 170—172° (decomp.); the hydrochloride (Lumière and Perrin, *loc. cit.*) and *picrate*, m. p. 186—189°, are described. When dissolved in concentrated sulphuric acid and the resulting solution

treated with water, the hydrochloride yields a substance, m. p. 225—226°, to which the author assigns the formula

Phenetyldiguanide condenses with ethyl oxalate in alcoholic solution,

yielding the compound $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{N} \begin{matrix} \text{C}(\text{NH})\cdot\text{NH}\cdot\text{C}(\text{NH}) \\ \text{CO} \text{---} \text{CO}\cdot\text{NH} \end{matrix}$, which has

m. p. 195—196° (decomp.); it forms *additive* compounds with phenols, and condensation products with formaldehyde and salicylaldehyde. When heated with acetic anhydride and sodium acetate, it yields a *diacetyl* derivative of the triazine base,

Ethyl phenyldiguanide-p-carboxylate, $\text{C}_2\text{H}_5\text{N}_5\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{Et}$, prepared from ethyl paminobenzoate, crystallises with one molecule of water in broad-pointed leaflets, m. p. 173°; the anhydrous compound has m. p. 177—178° (decomp.); the *hydrochloride* forms colourless leaflets or prisms; the *picrate* has m. p. 196—197°.

α-Naphthyldiguanide, $\text{C}_{12}\text{H}_{13}\text{N}_5$, forms colourless, iridescent leaflets, m. p. 154—155°, and yields a *hydrochloride* and a *picrate*, m. p. 200—203°.

m-Phenylenediguanide, $\text{C}_6\text{H}_4(\text{C}_2\text{H}_6\text{N}_2)_2$, prepared from *m*-phenylenediamine hydrochloride, has m. p. 165—167° (decomp.), and yields a *picrate*, m. p. 208—210°.

Diphenyldiguanide, $\text{C}_{12}\text{H}_8(\text{C}_2\text{H}_6\text{N}_2)_2$, obtained from benzidine (1 mol.) and dicyanodiamide (2 mols.), has m. p. 241°; the *hydrochloride* and *salphate* are described.

The interaction of benzidine hydrochloride and dicyanodiamide in equimolecular proportions yields 4'-amino-4-diphenyldiguanide,

which has m. p. 203—204°, and reacts with nitrous acid to form a diazonium compound which couples with α-naphthol, yielding a purple-red azo-dye; the azo-dyes obtained from β-naphthol, resorcinol, phenol, salicylic acid, and phenylmethylpyrazolone are also mentioned.

Phenyldiguanide-o-carboxylic anhydride,

prepared from anthranilic acid, is a crystalline powder, m. p. above 200°, and forms a sparingly soluble *hydrochloride*.

Phenylmethyldiguanide, $\text{NMePh}\cdot\text{C}_2\text{H}_5\text{N}_4$, obtained from methyl-aniline, crystallises in hygroscopic needles, which decompose when heated.

The interaction of phenylhydrazine hydrochloride and dicyanodiamide yields phenylguanazole (Pellizari, Abstr., 1892, 356), of which the *hydrochloride* and *picrate*, m. p. 225°, are mentioned.

Many of the diguanides described above give characteristic precipitates with potassium ferrocyanide, ammonium molybdate, and with nickel and cobalt salts.

Quantitative experiments on the precipitation of a large number of dyes by means of the diguanide hydrochlorides are also described.

F. B.

Distribution of Auxochromes in Azo-compounds. H. KAUFFMANN and W. KUOZL (*Ber.*, 1911, 44, 2386—2389).—For the study of the effect of the distribution of the auxochromes in azo-compounds (compare Kauffmann and Franck, *Abstr.*, 1906, i, 841), the compounds of the type $N_2[C_6H_4(OMe)_2]_2$, derived from quinol, resorcinol, and catechol, have been compared. These are coloured very differently; the quinol derivative is dark red, that from resorcinol is orange-red or orange, and the catechol derivative is orange-yellow. The rules as to the effect of the positions of the auxochromes therefore apply to azo-compounds. In hydrochloric acid solution the quinol derivative gives a blue, the resorcinol a red, and the catechol a carmine-red coloration.

Resorcinol benzoate couples with diazotised aniline to form *p*-benzeneazoresorcinol monobenzoate, which forms yellow crystals, m. p. 159°, and is hydrolysed to benzeneazoresorcinol, m. p. 169°.

By reduction of nitroresorcinol dimethyl ether with tin and hydrochloric acid, the hydrochloride of aminoresorcinol dimethyl ether is obtained in long, bluish-white needles. When diazotised, it couples with resorcinol to form 2:4-dimethoxybenzeneazoresorcinol,

which forms almost black crystals with a green reflex, and is soluble in sodium hydroxide with an orange-yellow coloration, m. p. 186°. Strong hydrochloric acid dissolves it with a dark red, sulphuric acid with a dark blue, coloration.

2:4:3':4'-Tetramethoxyazobenzene, $N_2[C_6H_3(OMe)_2]_2$, formed by methylation of the above substance with methyl sulphate, separates in red crystals, m. p. 181°.

3:4:3':4'-Tetramethoxyazobenzene prepared by reduction of nitroveratrole, forms yellow crystals, m. p. 163°.

2:5:2':5'-Tetramethoxyazobenzene (compare Baessler, *Abstr.*, 1884, 1329) forms dark red crystals, m. p. 142°, soluble in concentrated sulphuric acid with a violet-red, and in hydrochloric acid with a blue, coloration.

F. F. A.

Action of Sodium Sulphite and of Sodium Hydrogen Sulphite on Some Azo-dyes. ROBERTO LEPETIT and E. LEVI (*Gazzetta*, 1911, 41, i, 675—688. Compare *Abstr.*, 1909, i, 569. Nietzki and Helbach, *Abstr.*, 1897, i, 226).—From the reaction between sodium sulphite and nitrobenzeneazosalicylic acid (alizarin-yellow-R) the following substances were isolated: (1) *p*-aminobenzeneazosalicylic acid; (2) *p*-nitroaniline; (3) ammonia; (4) an amino-sulphosalicylic acid, to which the formula

is ascribed. The last-named substance crystallises in colourless, silky needles (and also in small, compact cubes), which dissolve in alcohol, giving a green, intensely fluorescent solution. The aqueous solution gives a cherry-red coloration with ferric chloride, and reduces ammoniacal silver solutions. Preparation of the substance by sulphonation of aminosalicylic acid shows that the substance is identical with that obtained by Mandt (*Ber.*, 1877, 10, 1701). It was

is possible to obtain salts with the heavy metals, but the arsenate crystallises in red needles. An acetyl derivative was obtained in the form of its sodium salt, which crystallises with $1\frac{1}{2}\text{H}_2\text{O}$. The barium salt also contains $1\frac{1}{2}\text{H}_2\text{O}$, but is not crystalline.

The action of sodium hydrogen sulphite is more vigorous than that of sodium sulphite, so that, working under the same conditions (in boiling water), after one hour most of the dye is decomposed into nitroaniline and aminosulphosalicylic acid without formation of aminobenzeneazosalicylic acid.

The reaction between sodium hydrogen sulphite and *p*-aminobenzeneazosalicylic acid (in an autoclave at 130°) proceeds similarly to that just described.

Benzeneazosalicylic acid and sodium sulphite yield (1) a substance, which crystallises in small, brown needles, m. p. 140° , which is possibly the hydrazo-compound, $\text{NHPh}\cdot\text{N}(\text{SO}_3\text{H})\cdot\text{C}_6\text{H}_4(\text{OH})\cdot\text{CO}_2\text{H}$; (2) aminosulphosalicylic acid.

Benzeneazosalicylic acid is more readily acted on by sodium hydrogen sulphite with formation of the following products: (1) aniline; (2) aminosulphosalicylic acid; (3) a substance which could not be isolated; (4) an amino-compound, m. p. $170-173^\circ$, which is a benzidine derivative; (5) a compound, m. p. $126-128^\circ$, which contains sulphur but no nitrogen.

Sodium hydrogen sulphite reacts with diphenylbisazosalicylic acid (chrysanin G) much less readily than with the preceding compounds. The products isolated were benzidine sulphate and aminosulphosalicylic acid.
R. V. S.

Aromatic Nitro-derivatives. II. ROBERTO CIUSA (*Gazzetta*, 1911, 41, i, 688—697. Compare *Abstr.*, 1907, i, 874).—The present paper deals with the action of picryl chloride on cyclohexanoneazine and on benzaldoxime, and the preparation of cyclohexanonemono- and dinitrophenylhydrazones is described. The author also finds that dinitro-*p*-cumene is strongly dissociated in formic acid solution, so that a mobile atom of hydrogen is not a necessary condition for the lability of aromatic polynitro-derivatives. It is suggested that the power of dissociation depends on the presence either of a free hydrogen atom in the nucleus or of a halogen or nitro-group in the ortho-position with respect to another nitro group.

2:4:6:4'-Tetranitrohydrazobenzene gives a potassium salt, $\text{C}_6\text{H}_2(\text{NO}_2)_4\text{N}_2\cdot\text{K}$, which crystallises in small, dark needles with a violet sheen.

2:4:6:4'-Tetranitrohydrazobenzene when heated with concentrated nitric acid yields 2:4:6:4'-tetranitroazobenzene,

which forms orange-red needles, m. p. $163-164^\circ$. It dissolves in alkalis with difficulty, giving a red coloration.

cyclohexanoneazine (from cyclohexanone and hydrazine hydrate) has b. p. $165^\circ/25\text{ mm.}$, m. p. 35° . On treatment with picryl chloride, it yields cyclohexanonetetrinitrophenylhydrazone, $\text{C}_6\text{H}_{10}\cdot\text{N}:\text{N}\cdot\text{C}_6\text{H}_2(\text{NO}_2)_4$, which crystallises in flat, red needles, m. p. 133° , and dissolves in alkali, giving a reddish-brown coloration. cyclohexanone-2:4-dinitro-

phenylhydrazones, $C_6H_{10} \cdot N \cdot NH \cdot C_6H_4(NO_2)_2$, forms golden-yellow solids, m. p. 145° . cycloHexanone-p-nitrophenylhydrazones,

$C_6H_{10} \cdot N \cdot NH \cdot C_6H_4 \cdot NO_2$, crystallises in yellowish-brown needles, m. p. 146° ; it is insoluble in water, and may be used to detect cyclohexanone in water.

When α -benzaldehyde is heated with picryl chloride in alcoholic solution for two hours, picramide is obtained.

A nitro-group is eliminated from trinitro- ψ -cumene when treated with alkali, and a potassium salt, $C_6Me_3(NO_2)_2 \cdot OK$, can be obtained. By the action of dilute hydrochloric acid, this salt is converted into a yellow substance.

R. V. S.

Hydrazo-compounds. VII. Methylhydrazotoluene, Methyltolidine, and Ethylbenzidine. BERTHOLD RASSOW and ALAN BECKER (*J. pr. Chem.*, 1911, [ii], 64, 329—351. Compare this vol., 820, 821).—N-Methylhydrazo-o-toluene, $C_6H_4Me \cdot NH \cdot NMe \cdot C_6H_4Me$, prepared by heating a benzene solution of hydrazo-o-toluene with excess of methyl sulphate and magnesium oxide for thirty-six to forty hours in an atmosphere of carbon dioxide; it crystallises in rhombic, rectangular, or almost square plates, m. p. 84° .

N-Methyl-o-tolidine, $NHMe \cdot C_6H_3Me \cdot C_6H_3Me \cdot NH_2$, obtained in the form of its hydrochloride, $C_{15}H_{18}N_2 \cdot 2HCl$ (decomp. 260 — 265°), by the addition of concentrated hydrochloric acid to an alcoholic solution of the preceding compound, has m. p. 85° ; it yields an unstable, yellowish-brown platinumchloride, $C_{15}H_{18}N_2PtCl_6$, a picrate, crystallising in yellow, microscopic needles, which decompose at 184 — 186° , and a dibenzoyl derivative, $NHBz \cdot C_6H_3Me \cdot C_6H_3Me \cdot NMeBz$, m. p. 156° ; when heated with salicylaldehyde in alcoholic solution, it forms a salicylidene derivative, $NHMe \cdot C_6H_3Me \cdot C_6H_3Me \cdot N \cdot CH \cdot C_6H_4 \cdot OH$, which crystallises in needles, m. p. 120° . It reacts with one or two mols. of nitrous acid, yielding (I) 4-methylamino-3:3'-dimethyldiphenyl 4'-diazonium chloride, $NHMe \cdot C_6H_3Me \cdot C_6H_3Me \cdot N_2Cl$, and (II) 4-methylnitrosoamino-3:3'-dimethyldiphenyl-4'-diazonium chloride,

4-Methylamino-3:3'-dimethyldiphenyl-4'-azo- β -naphthol,

prepared by coupling the diazonium compound (I) with β -naphthol, forms lustrous, dark red crystals, which have m. p. 90 — 92° and decompose at 120° .

4-Methylnitrosoamino-3:3'-dimethyldiphenyl-4'-azo- β -naphthol,

prepared from (II) and β -naphthol, has m. p. 173° , and is converted into the preceding compound when heated with alcoholic hydrogen chloride.

4-Methylamino-3:3'-dimethyldiphenyl-4'-azo-p-dimethylaniline,

begins to decompose at 100° , and yields a dark red hydrochloride: the nitroso-derivative, prepared from (II) and dimethylaniline, forms reddish-yellow, triclinic prisms, which have m. p. 160° , and decompose at 180° . It combines with benzenediazonium chloride, yielding 4-benzeneazo-4-methylamino-3:3'-dimethyldiphenyl-4'-azo-p-dimethylaniline,

$\text{Ph}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{Me}(\text{NHMe})\cdot\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{N}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{NMe}$, which decomposes at $180^\circ\text{--}190^\circ$.

Sodium 4-methylamino-3:3'-dimethyldiphenyl-4'-azo- β -naphthol-(3:6)-disulphonate, $\text{C}_{15}\text{H}_{11}\text{O}_2\text{S}_2\text{Na}_2$, prepared from the diazonium compound 1 and R-malt, has no definite m. p., and couples with benzenediazonium chloride, yielding *sodium 5-benzeneazo-4-methylamino-3:3'-dimethyldiphenyl-4'-azo- β -naphthol-(3:6)-disulphonate*,

$\text{NPh}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{Me}(\text{NHMe})\cdot\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{N}\cdot\text{N}\cdot\text{C}_{10}\text{H}_7(\text{SO}_3\text{Na})_2\cdot\text{OH}$, which is dark red and dyes cotton reddish-violet; with diazotised salphanic acid it forms a deep bluish-violet *bisazo-dye*.

N-Ethylbenzidine $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4\cdot\text{NHEt}$, obtained by heating a benzene solution of hydrazobenzene with ethyl sulphate in the presence of magnesium oxide, crystallises in leaflets or needles, m. p. $73\text{--}74^\circ$.
F. B.

Electrochemistry of Proteins. VII. The Mode of Formation and Ionisation of the Compounds of Proteins with Inorganic Acids and Bases. T. BRAILSFORD ROBERTSON (*J. Physical Chem.*, 1911, 15, 521—550. Compare this vol., ii, 460).—The author propounds the hypothesis that the combining power of protein for acids and bases resides elsewhere than in the terminal NH_2 and CO_2H groups of the protein chain. The typical group $-\text{CO}\cdot\text{NH}-$ (alternatively $-\text{C}(\text{OH})\cdot\text{N}-$) is held to be the seat of the amphoteric properties. The main arguments are as follows.

The soluble neutral hydrochloride of edestin contains nine times as much acid as the insoluble hydrochloride. Hence there must be nine or a multiple of nine basic centres in the edestin molecule. On a probable molecular weight of 7000, nine NH_2 groups correspond with more than 10% of the total nitrogen. In caseinogen the maximum combining capacity for alkali is sixteen times the minimum amount required to render the caseinogen soluble. On a probable molecular weight of 17,600 this requires 12½% of the total oxygen to be in the terminal CO_2H groups. Similar calculations made for egg-albumin also lead to percentages which are too high to be consistent with the catenary structure of the protein molecule.

The non-hydrolysable character of the protein salts is presumptive evidence that they are not ordinary amino-salts or carboxylates in the formation of which water is split off. The anions and cations of caseinogen and ovimucoid salts are protein ions, and the dissociation of potassium caseinogenate is not diminished by potassium chloride.

Burgarski and Liebermann showed (*Abstr.*, 1898, i, 716), by potentiometric methods, that as many chlorine as hydrogen ions are removed from circulation when egg-albumin is dissolved in dilute hydrochloric acid. A mixture of ovimucoid hydrochloride with potassium caseinogenate has at first a conductivity equal to the sum of the conductivities of the constituent solutions, and only very slowly deposits caseinogen as a result of the formation of potassium chloride, since the inorganic constituents of the protein salts are combined in a non-dissociable form.

From analysis of the anodic and cathodic solutions after electrolysis of potassium caseinogenate, the loss of caseinogen from the anodal

region, is about double the loss from the cathodal region. This is in harmony with the assumption that the positive and negative ions of caseinogen are of about equal mass and mobility. The formula of protein being written $R^1C(OH) \cdot NR^2$, the ionised salts may be written $R^1C(ONa)'' + HN(OH'')R^2$ and $R^1C(OH)'' + HNCI''R^2$ respectively. The ions are assumed to be bivalent from the electrochemical equivalents.

Kossel has drawn attention to the fact that the combining capacity of a protein for acids is proportional to the diamino-acid content, and the combining capacity for bases is proportional to the dicarboxylic acid content. Hence it is probable that the $-C(OH) \cdot N-$ groups function only when in contiguous pairs. This leads to the formulae $R^1 \begin{matrix} C(OK)'' + NH(OH'')R^2 \\ C(OK)'' + NH(OH'')R^2 \end{matrix}$ and $R^2 \begin{matrix} C(OH)'' + NHCl'' \\ C(OH)'' + NHCl'' \end{matrix} > I_2$ for the potassium salt and the hydrochloride of protein respectively.

These formulae are in agreement with the conductivity and freezing-point determinations in the case of ovimucoid dihydrochloride. Ovimucoid monohydrochloride is supposed to be

R. J. C.

Precipitation of Protein by Zinc Sulphate. FARTZ LIEBIG (*Zeitsch. physiol. Chem.*, 1911, 74, 360-391).—A detailed discussion of the literature leads to the conclusion that the adsorption hypothesis does not explain adequately the formation of metallic albuminates. It is undesirable to extend to proteins the conclusions based on experiments made with inorganic colloidal material.

In a series of experiments the proteins of horse-serum were precipitated by increasing quantities of zinc sulphate, and the amount of protein and zinc salt remaining in the filtrate determined, whence the composition of the precipitate could be calculated. It is found that, under certain conditions, the amount of zinc in the precipitate is independent of the concentration of the protein, and also of the initial concentration of the zinc salt. The power of protein to form a zinc salt increases on dilution, but a maximum is soon reached. The results are not in agreement with the adsorption theory, and the change is better represented as a chemical interaction between an amphoteric and a non-amphoteric electrolyts leading to an equilibrium: $ZnSO_4 + 2Na \text{ protein} \rightleftharpoons Na_2SO_4 + Zn(\text{protein})_2$. The left-hand side of the equation preponderates so long as protein is present in excess, but the amount of precipitate increases on standing, and especially on dilution. When the amount of metallic salt is increased, a point is reached when a sparingly soluble substance is formed, and the reaction is almost entirely in the sense of the equation from left to right. A still further increase in concentration of the metallic salt causes reaction in the opposite direction, and the precipitate will begin to dissolve. For the full discussion of the results the original should be consulted.

E. F. A.

What is the Cause of the Separation of Albumin in Bottled Beer which has been Subjected to Normal Treatment in Brewery and Cellar? FRITZ EMSLANDER (*Koll. Chem. Beihfte.*, 1911, 3, 47—84).—The conditions favourable to the separation of albumin are discussed with reference to the literature on the subject, and the conclusion is reached that the process is determined primarily by electrochemical effects resulting from the presence of electrolytes. These bring about chemical change in the molecules of albumin, and the transformation is accompanied by alterations in the surface-tension and potential difference between the colloidal particles and the aqueous medium. Coagulation results, and this leads ultimately to turbidity and the deposition of solid substances. H. M. D.

The Hydrolytic Action of Hydrogen Peroxide. CARL NEUBERG and SOICHIRO MIURA (*Biochem. Zeitsch.*, 1911, 36, 37—43).—Hydrogen peroxide in the presence of a manganese or iron salt will bring about at the ordinary temperature the hydrolysis of a number of compounds of high molecular weight. Egg-albumin after treatment yields 10% of its nitrogen as ammonia when heated with magnesia. Substances of an aldehydic and ketonic nature are also formed. Gelatin under similar conditions gives 10.4% of its nitrogen as amide-nitrogen.

Starch, soluble starch, and glycogen are hydrolysed with formation of reducing and fermentable sugars, which yield mixed phenylosazones. Phenylglucosazone is obtained from the products from soluble starch, and phenylmaltosazone from those from glycogen. Inulin gives levulose.

Yeast nucleic acid gives 23.2% of its nitrogen as amido-nitrogen, and phosphoric acid is set free. With sodium chondroitin sulphate, sulphuric acid is liberated, whilst lecithin yields fatty acids. W. J. Y.

The Reactions between Ferments and Anti-ferments. MARTIN JACOBY (*Biochem. Zeitsch.*, 1911, 34, 485—494. Compare Abstr., 1907, i, 811; ii, 108; 1908, i, 236; ii, 743).—Previous observations that the combination between rennet and anti-rennet of serum is destroyed by acid is confirmed. If acid is allowed to act on serum for some time, the anti-rennet is destroyed. Neither the ferment, anti-ferment, nor the combination are soluble in ether. If rennet solution is shaken, its fermentative action is diminished, and can be neutralised by a smaller quantity of serum. S. B. S.

Action of Oxydases. I. REGINALD O. HERZOG and A. POLOTZKY (*Zeitsch. physiol. Chem.*, 1911, 73, 247—257. Compare Engler and Herzog, Abstr., 1909, ii, 495).—The peroxydase was prepared from sugar beet, and its action in presence of hydrogen peroxide tested on the leuco-base of brilliant-green, on a mixture of *p*-phenylenediamine and dimethylaniline, and on vanillin. Dyes are formed in the first two cases, and a precipitate in the last. The optimum reaction is shown to depend on the concentration of each of the three reacting substances. The change in the case of brilliant-green can be followed colorimetrically. In addition to the formation of colour there is a

bleaching action also brought about by the oxydase. Complete bleaching takes place when the proportion of leuco-base is small compared with that of hydrogen peroxide, provided an excess of enzyme is present. The formation of the dye is much more rapid than the bleaching.

The three possible combinations of mixtures of two of the three reacting substances were prepared and set aside for fourteen hours before the third substance was added. The mixture leuco-base + peroxide reacts the most quickly, that of peroxydase + peroxide is slower, whilst peroxydase + leuco-base shows a marked induction period, and the rate of dye formation is slow. The velocity of the bleaching reaction is much the same for the first and third mixtures, but less for the second. The long induction period indicates that chemical changes, in particular, the formation of additive products, must take place between the components before the formation of colour begins. The experiments indicate that a compound of leuco-base and peroxydase is formed, and that the addition of peroxide displaces the leuco-base and forms a true oxydase from the peroxydase and peroxide. Formation of dye does not take place until the concentration of the active oxydase is sufficient. E. F. A.

Action of Oxydases. II. REGINALD O. HERZOG and A. MUM (Zeitsch. physiol. Chem., 1911, 73, 258—265. Compare preceding abstract).—The oxydase extracted from horse-radish was tested against vanillin in presence of hydrogen peroxide, and the amount of dehydrodivanillin formed was weighed. Experiments were made with varying proportions of enzyme and hydrogen peroxide. Its filtrate was tested in each case with fresh oxydase solution, and with hydrogen peroxide and guaiacum in order to test whether active peroxydase still remained. The enzyme is destroyed when the relative concentration of hydrogen peroxide is too large; when this is small the amount of change is approximately proportional to the amount of peroxydase added. The amount of change depends on the proportions of each of the three reacting substances, and the phenomena differ from typical catalysis. The action of peroxydase is classed with the so-called induced reactions. E. F. A.

The Peroxydase of Milk. W. GRIMMER (Milchw. Zentr., 1911, 7, 395—402).—The peroxydase reaction of fresh milk is shown to be due, not to the presence of inorganic catalysts, but to that of a substance closely connected with the lactalbumin. This is indicated by the similar behaviour of milk-peroxydase and lactalbumin towards precipitating agents and solvents, and, further, by the fact that all compounds which tend to denaturise lactalbumin, such as alcohol, acetone, ether, chloroform, and concentrated acids and alkalis, also lead to the destruction of the enzyme. Putrefaction has the same effect. It is suggested that the enzyme produced in the cells of the mammary gland, and liberated by the destruction of these, is either a protein possessing physical and chemical properties similar to those of lactalbumin, or that it becomes adsorbed by the latter and cannot be separated by ordinary means. H. R. H.

Organic Chemistry.

Catalytic Reactions at High Temperatures and Pressures.
[XII. Decomposition of Hexane and cycloHexane; Isomerisation of cycloHexane. WLADIMIR N. IPATIEFF and N. DOWGIELEWITSCH *Ber.*, 1911, 44, 2987—2992).—At ordinary pressures, hexane and cyclohexane are decomposed when passed through an iron tube at 650—700°, the decomposition being accelerated by the presence of alumina; hexane decomposes more readily than cyclohexane. The gases thereby produced consist of saturated hydrocarbons, hydrogen, ethylene, propylene, and probably isobutylene, whilst the liquid polymerisation product contains a very small proportion of unsaturated hydrocarbons. No hydrocarbons were obtained which reacted with a nitrating mixture or with permanganate.

The course of reaction is quite different under high pressures, taking place at a much lower temperature. With hexane, at 510°, the increase in pressure takes place so rapidly that an explosion occurs, so that cyclohexane only was used in these experiments. It was heated for four hours at 500—510° in the presence of alumina, at a pressure of 110—120 atmospheres; no reaction takes place at this temperature in the absence of alumina. After removal of the ethylene hydrocarbons from the liquid polymerisation product by means of sulphuric acid, the remaining liquid was divided into eleven fractions, none of which decolorised permanganate. The first three fractions, 45—80°, contained polymethylene hydrocarbons, among which was methyl cyclopentane, but no saturated hydrocarbons. The fractions VI—XI, 125—280°, reacted with a nitrating mixture, and therefore contained benzene hydrocarbons; nitro-compounds were also obtained from fractions VI (125—150°) and VII (150—170°). The higher fractions contain polynuclear hydrocarbons as well as saturated hydrocarbons.

Methylcyclopentane was isolated by refractionation of the first three fractions, and identified by its physical properties and transformation into the nitro-compound. During its formation from cyclohexane there is also the possibility of hexylene being formed, and this compound was also identified. This isomerisation of cyclohexane takes place only at high pressures and in the presence of alumina; at ordinary pressures, even at 760°, no methylcyclopentane could be found in the products of decomposition.
 T. S. P.

Polymerisation of Ethylene Hydrocarbons at High Temperatures and Pressures. WLADIMIR N. IPATIEFF (*Ber.*, 1911, 44, 2973—2987).—Both ethylene and isobutylene when heated in an iron tube under a pressure of about 70 atmospheres (compare Ab-tr., 1907, l. 5) undergo rapid polymerisation at 380—400°. The liquid polymerisation products thus obtained consist of mixtures of saturated, ethylenic, and polymethylene hydrocarbons. The fractions boiling below 100° consist chiefly of the saturated and ethylene hydrocarbons, whilst the

polymethylene compounds are found chiefly in the higher-boiling fractions, the proportion being the greater the higher the boiling point. This holds, however, only for fractions boiling below 254°; above that temperature hydrocarbons are obtained which are poorer in hydrogen than the polymethylene compounds.

The following compounds were identified in the polymerisation product obtained from ethylene: isopentane, hexane, heptane, octane, nonane, amylene, hexylene, nonanaphthene, α - and β -decanaphthene, undeca-, dodeca-, tetradeca- and pentadeca-naphthenes. In the case of isobutylene the polymerisation product also contained some hydrocarbons which reacted with a nitrating mixture and with potassium permanganate, and were insoluble in sulphuric acid (D 184).

In the presence of alumina the polymerisation of ethylene gave similar results to those obtained in its absence.

At atmospheric pressure ethylene does not polymerise, even at 600°. The ethylene hydrocarbons are probably produced by the polymerisation of ethylene itself, or from the polymethylenes by fission of the ring (compare preceding abstract). The saturated hydrocarbons are formed either by the hydrogenisation of the closed-chain hydrocarbons with fission of the ring, or else by fission of the side-chain from the polymethylene nucleus.

T. S. F.

Preparation of Sulphurous Acid Derivatives of Unsaturated Hydrocarbons. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 236386).—When the unsaturated hydrocarbons of general formula $CR_1:CR:CR:CR_2$ (where R is hydrogen, alkyl, or aryl group), are treated with sulphurous acid, they yield colourless compounds, which when containing a small amount of sulphurous acid are fairly soluble in water, but an increase of the amount renders them insoluble.

When β -dimethyl- Δ^2 -butadiene is saturated with sulphur dioxide in aqueous solution, it stiffens to a colourless substance somewhat resembling meerschäum; if shaken for some time with excess of sulphurous acid, an insoluble compound is formed, but if the shaking is interrupted at the right time and the solution carefully evaporated, a compound of β -dimethylbutadiene with sulphurous acid separates in long needles. The compound, prepared from isoprene and sulphurous acid, separates in colourless flakes.

F. M. G. M.

α -Iodo- Δ^2 -hexene. JULIUS VON BRAUN and H. DEUTSCH (Ber. 1911, 44, 3062—3065).—The magnesium compound of a bromo- Δ^2 -hexene, $CHMe:CH[CH_2]_3MgBr$, obtained by the action of magnesium on $\alpha\delta\epsilon$ -trihromohexane (Braun and Sobiecki, this vol. i, 413), is converted by the action of iodine into α -iodo- Δ^2 -hexene, $CHMe:CH[CH_2]_3CH_2I$. This is an almost colourless liquid, b. p. 70—75°/33 mm., and combines with trimethylamine in alcoholic solution, yielding Δ^2 -hexenyltrimethylammonium iodide, $C_8H_{11} \cdot NMe_3 \cdot I$, m. p. 110°, which is extremely hygroscopic, and at once forms a yellow oil on exposure to air.

By the exhaustive methylation of α -pipecoline, Merling (Abstr. 1891, 1506) obtained a base, $C_8H_{11} \cdot NMe_3$, which forms a methiodide isomeric with the above compound, and, accordingly, must have the constitution $CH_2:CH[CH_2]_4 \cdot NMe_3$.

F. R.

Specific Gravity of Absolute Ethyl Alcohol at 25°. ANTON KALLAS (*Ber.*, 1911, 44, 2881—2884).—The author finds the density of absolute ethyl alcohol, prepared by distillation of 99.8% alcohol over calcium, to be D_4^{25} 0.78513, which agrees with Winkler's value, 0.78509 (*Abstr.*, 1905, i, 850), within the error of experiment. This necessitates a correction in the water-content of the alcohol used by him in his measurements of the velocity of esterification of organic acids (compare *Abstr.*, 1908, ii, 27, 28, 936), since his previous results were based on Mendelëff's values for the density of alcohol.

Redeterminations of the velocity of esterification of benzoic acid with hydrogen chloride as catalyst give results in agreement with those obtained by Goldschmidt for alcohol distilled over calcium (*Abstr.*, 1907, ii, 852).

The water-content of alcohol can be determined more accurately by measurement of the density than by measurement of the velocity of esterification, as recommended by Goldschmidt, even when it is less than 0.1%.

T. S. P.

Use of Liquid Ammonia in Chemical Reactions. Alkylloxides. E. CHABLAY (*Compt. rend.*, 1911, 153, 819—821. Compare Dohy, *Abstr.*, 1903, i, 546; Perkin and Pratt, *Trans.*, 1909, 35, 159).—The preparation of the alkylloxides of alkali earth metals has been realised by bringing about double decomposition between a sodium alkylxide and the metallic nitrate in liquid ammonia solution. The resulting sodium nitrate, being soluble in the ammonia, can be separated from the alkylxide. A second method consists in allowing an alcohol to act on a solution of calcium in liquid ammonia, when the action follows the course $2ROH + Ca(NH_3)_2 = Ca(OR)_2 + 4NH_3 + H_2$. A number of barium and strontium alkylloxides have also been prepared in this way.

W. O. W.

Catalytic Dehydration of *sec.*- and *tert.*-Pinacolyl Alcohols. FRANÇOIS COUTURIER (*Bull. Soc. chim.*, 1911, [iv], 9, 898—901).—When these alcohols are dehydrated by Sabatier and Seuderens' method, using the apparatus designed by Bouveault (*Abstr.*, 1908, i, 117), the secondary alcohol (methyl*tert.*-butylcarbinol),

pives rise to pinacolin, whilst the tertiary alcohol, dimethylisopropylcarbinol, forms β -dimethyl- Δ^2 -butylene with a small amount of β -dimethyl- Δ^3 -butylene (compare Henry, *Abstr.*, 1907, i, 374; 1909, i, 74, and Delacre, *Abstr.*, 1906, i, 921; 1907, i, 459). Those results support Delacre's view that *sec.*-pinacolyl alcohol is not readily isomerised, and are in opposition to Henry's results (*loc. cit.*), which indicate that the haloid esters of this alcohol undergo isomerisation when heated (*Abstr.*, 1908, i, 881).

T. A. H.

Accessory Products in the Hydrolysis of (I.) Crude Pinacone; (II.) Pure Pinacone. MAURICE DELACRE (*Bull. Soc. chim.*, 1911, [iv], 9, 885—889, 889—898).—A detailed revision of the work done by Couturier (*Abstr.*, 1893, i, 244) and by Richard and Anglais (*Abstr.*, 1910, i, 462) on the identification of the by-products formed in the preparation of pinacolin from pinacone.

From 10.3 kilograms of residues from the preparation of pinacol from crude pinacone, 6.277 kilograms of material boiling at $200-220^\circ$ were obtained, the remainder, after allowing 2.27 kilograms for residue and loss, being divided into eleven fractions boiling between 140° and 200° . From the portion b. p. $200-220^\circ$, two fractions, b. p. $213-214^\circ$ and $214.5-218^\circ$, were isolated. The first of these had approximately the composition $C_9H_{14}O$, and gave an oxime, m. p. 161° , and a semicarbazone, m. p. 187° . A portion of this fraction boiling at 214° , on the contrary, gave with hydroxylamine two substances, of m. p. 60° and 88° respectively. The fraction is therefore a mixture, and it is impossible at present to say whether it contains isophorone and deoxymesitylic oxide (Harries and Hubner, Abstr., 1897, i, 549), in the low boiling portion of the residues, diisopropenyl (Abstr., 1896, i, 591) and a hydrocarbon, C_7H_{14} , b. p. $60-63^\circ$, were found.

In the second paper details are given of a still more exhaustive fractionation of by-products from the preparation of pinacolin from crude pinacone. No mesitylene could be detected, but a substance, $C_9H_{14}O$, b. p. 210° (approx.), giving an oxime, m. p. 75° , and a semicarbazone, m. p. 196° , was obtained; this may be isophorone or a new isomeride of this substance. A similar examination of the by-products resulting from the preparation of pinacolin from pure pinacone gave analogous results.

T. A. H.

Autoxidation of Aliphatic Amino- and Polyhydroxy derivatives. II. WILHELM TRAUBE (*Ber.*, 1911, 44, 3141-3144). Compare Abstr., 1910, i, 294).—Cuprammonium oxide and the complex copper salts of aliphatic amino- and hydroxy-compounds are autoxidisable. The experiments with the latter have now been made with barium hydroxide instead of sodium hydroxide, the alkali being saturated with cupric hydroxide and oxidation effected at about 70° . Under these conditions carbon dioxide is formed in considerable quantity, and oxalic acid appears as well as formic acid.

Glycerol is oxidised to the extent of about 20% to carbon dioxide and oxalic acid, $C_3H_8O_3 + O_2 = C_2H_2O_4 + CO_2 + 3H_2O$, and about 80% to formic and oxalic acids, $C_3H_8O_3 + O_2 = C_2H_2O_4 + H_2CO_2 + 2H_2O$.

The oxidation of glyceric acid, barium gluconate, glycollic acid, glycine, and lactic acid has been studied in like manner.

E. F. A.

$\alpha\beta$ -Trihydroxybutane; its Conversion into Furan Derivatives and Erythritol. HENRI PARISELLE (*Ann. Chim. Phys.*, [1911] [viii], 24, 315-410).—This paper gives a detailed, connected account of results already published (Abstr., 1908, i, 496; 1909, i, 282, 691; 1910, i, 353, 463), adding new data regarding certain of the substances described, and giving comparisons of allylcarbinol with allyl alcohol and of $\alpha\beta$ -trihydroxybutane with $\alpha\beta$ -trihydroxybutane and glycerol.

Allylcarbinol, D^{20}_D 0.848, n^{20}_D 1.421, prepared as described already (Abstr., 1909, i, 282), on treatment with phosphorus tribromide and hydrogen bromide furnishes some $\alpha\gamma$ -dibromobutane along with a small yield of the corresponding bromide [bromo- Δ^2 -butylene],

D^{20} 1.355, D^{20} 1.33, n^{20}_D 1.465, b. p. $97-99^\circ/760$ mm., which on treatment

with solid potassium hydroxide gives Δ^2 -butadiene, $\text{CH}_2\text{:CH}\cdot\text{CH}\cdot\text{CH}_2$, identified by conversion into tetrabromobutane, m. p. 117—118° (see below). The acetate has D^{20}_D 0.93, D^{20}_D 0.918, n^{20}_D 1.411, and readily combines with bromine to form γ -dibromobutyl acetate, D^{20}_D 1.73, n^{20}_D 1.508, b. p. 135°/16 mm. (compare Wagner, Abstr., 1894, i, 563). Butylcarbinol formal, $\text{CH}_2(\text{O}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CH}_2)_n$ has D^{20}_D 0.897, D^{20}_D 0.88, n^{20}_D 1.4333 (Abstr., 1909, i, 282).

The methyl ether of allylcarbinol, $\text{CH}_2\text{:CH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OMe}$, D^{20}_D 0.817, D^{20}_D 0.8, n^{20}_D 1.398, b. p. 68—69°, was prepared by the action of zinc dust in alcohol on γ -dibromobutyl methyl ether, n^{20}_D 1.5158, b. p. 16°/16 mm. (compare Lespieau, Abstr., 1907, i, 580). γ -Dibromobutyl ethyl ether, D^{20}_D 1.662, D^{20}_D 1.614, n^{20}_D 1.498, b. p. 98°/12 mm. (compare Abstr., 1910, i, 353), on treatment with hydrogen bromide forms only β -dibromobutane, D^{20}_D 1.80, n^{20}_D 1.507, b. p. 64°/13 mm. (compare Demjanoff, Abstr., 1895, i, 161). The phenylurethane of allyl alcohol has m. p. 70° and is crystalline; that of allylcarbinol is a syrup.

α - β -Tribromobutane, D^{20}_D 2.276, D^{20}_D 2.234, n^{20}_D 1.574, prepared as described already (Abstr., 1908, i, 496), when heated with boiling water or moist silver oxide gives 3-hydroxytetrahydrofuran (Abstr., 1909, i, 691), D^{20}_D 1.107, D^{20}_D 1.07, n^{20}_D 1.4478, MR 21.91 (calc., 21.61), a colourless, syrupy liquid, and with potassium acetate solution yields the triacetin of α - β -trihydroxybutane, D^{20}_D 1.152, D^{20}_D 1.13, n^{20}_D 1.436, b. p. 150°/11 mm., or 158°/17 mm., which on hydrolysis by baryta gives the trihydric alcohol, D^{20}_D 1.21, D^{20}_D 1.18, n^{20}_D 1.47, b. p. 179°/13 mm. (compare Wagner, *loc. cit.*). This yields a triphenylurethane, m. p. 149—152°, in colourless needles, and a δ -ethyl ether, D^{20}_D 1.08, n^{20}_D 1.45, b. p. 130°/14 mm., of which the diphenylurethane is crystalline, and melts at 98—99°. In the formation of this ether, as in that of the methyl ether, some 3-hydroxytetrahydrofuran is formed (Abstr., 1909, i, 691). γ -Dibromobutyl alcohol, D^{20}_D 2.02, D^{20}_D 1.98, n^{20}_D 1.548, b. p. 114°/11 mm. (compare Wagner, *loc. cit.*, and Abstr., 1909, i, 282), gives a phenylurethane, m. p. 70—71°. α -Bromo- Δ^2 -butylene oxide with (1) potassium acetate gives the diacetin of α - β -trihydroxybutane (Abstr., 1909, i, 691), D^{20}_D 1.17, D^{20}_D 1.15, n^{20}_D 1.446, b. p. 161—163°/8 mm.; (2) acetic anhydride and zinc chloride yields α -bromo- γ -diethoxybutane, $\text{CH}_2\text{Ac}\cdot\text{CHAc}\cdot\text{CH}_2\cdot\text{CH}_2\text{Br}$, D^{20}_D 1.44, n^{20}_D 1.473, b. p. 140—141°/13—14 mm., a colourless liquid, having an odour like that of ethyl acetate, and (3) with potassium acetate furnishes α -acetoxy- Δ^2 -butylene oxide, $\text{CH}_2\text{O}\text{---}\text{CH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OAc}$, D^{20}_D 1.12, n^{20}_D 1.446, b. p. 189—192°, a colourless liquid having an odour recalling that of ethyl acetate. α -Ethoxy- Δ^2 -butylene oxide, D^{20}_D 0.957, D^{20}_D 0.934, n^{20}_D 1.415 (Abstr., 1910, i, 353), is converted by hydrogen chloride into β -chloro- β -hydroxy- δ -ethoxybutane.

Δ^2 -Butylene- γ -oxide, $\text{CH}_2\text{O}\text{---}\text{CH}\cdot\text{CH}\cdot\text{CH}_2$, precipitates a solution of magnesium chloride in alcohol and water, polymerises readily, is easily hydrated to form erythrol, from which natural and racemic erythritols may be prepared (compare Abstr., 1910, i, 463), and on

treatment with bromine in chloroform gives $\alpha\beta$ -dibromo- Δ^1 -butylene oxide, D^0 2.028, n_D^{20} 1.542, b. p. $99^\circ/13$ — 14 mm. The latter with hydrogen bromide in chloroform gives $\alpha\gamma\delta$ -tribromo- β -hydroxybutane, b. p. 148 — $150^\circ/14$ mm. This in turn reacts with phosphorus pentabromide at 150° to give $\alpha\beta\gamma\delta$ -tetrabromobutane, m. p. 117 — 117.5° , crystallising in colourless needles (compare Griner, Abstr., 1893, 251). Ciamician and Magnaghi's form of this substance, m. p. 38 — 39° (Abstr., 1886, 521), was not obtained. By the action of bromine on erythrol [Δ^1 -butylene- $\gamma\delta$ -diol], two $\alpha\beta$ -dibromo- $\gamma\delta$ -dihydroxybutanes, the one crystalline, m. p. 88 — 89.5° , and probably identical with that of Grimaux and Cloez (Abstr., 1890, 730) and the other liquid, are formed.

T. A. H.

Chloro-ethers. VI. $\alpha\beta$ -Dichloro-*n*-propyl Ether, $\alpha\beta\gamma$ -Trichloro-*n*-propyl Ether, and Tetrachloro-*n*-propyl Ether. GIUSEPPE ODDO and GUIDO CUSMANO (*Gazzetta*, 1911, 41, ii, 224—245). Compare Oddo and Mameli, Abstr., 1904, i, 280; 1906, i, 134, 419, and the two following abstracts).—In the present paper the authors continue the study of the above dichloro- and trichloro-ethers, reporting new decomposition products and condensations, and describe also a tetrachloro-ether.

In the chlorination of *n*-propyl ether in diffuse light at 25° , in addition to the dichloro-ether, the following substances are produced in small quantities: (1) α -monochloropropaldehyde; (2) a substance, b. p. 144 — 147° , probably a monochloropropyl ether; (3) the trichloro-ether. When the dichloropropyl ether is treated with sulphuric acid at 135 — 140° , α -chloropropaldehyde, b. p. 85 — 86° , is obtained (compare Brochet, Abstr., 1896, i, 114). This aldehyde polymerises readily on keeping (although it is stable in a sealed tube); the polymeride is a white powder, which does not melt, but is reconverted into the liquid aldehyde at 170 — 200° . It appears to form a compound with water, but the hydrate could not be obtained in a crystalline state. It also forms an alcoholate with propyl alcohol, but this was not isolated.

When $\alpha\beta$ -dichloro-*n*-propyl ether is boiled with water and the product fractionated, α -chloropropaldehyde and β -chloropropional, $\text{CHMeCl}\cdot\text{CH}(\text{OPr})_2$, are obtained. The action of propyl alcohol also results in the formation of the latter substance.

When $\alpha\beta$ -dichloro-*n*-propyl ether is boiled for about one hundred hours, *n*-propyl- β -chloropropylene ether, $\text{CMeCl}\cdot\text{CH}\cdot\text{OPr}$, is obtained as a colourless liquid, b. p. 145 — 146.5° . The action of bromine on this unsaturated compound yields β -chloro- $\alpha\beta$ -dibromopropyl ether,

which is a mobile liquid, b. p. 140 — $142^\circ/20$ mm. With pyridine it yields a compound, m. p. 216 — 217° , which gives a platinumchloride m. p. also 216 — 217° .

In view of the above reactions it is shown that the dichloro-ether is $\alpha\beta$ -dichloro-*n*-propyl ether, and this is confirmed by its synthesis from α -chloropropaldehyde, propyl alcohol, and hydrogen chloride.

$\alpha\beta\gamma$ -Trichloro-*n*-propyl ether is obtained mixed with the tetrachloro-ether by chlorinating *n*-propyl ether or $\alpha\beta$ -dichloro-*n*-propyl

ether on a boiling brine-bath; it has b. p. 115—120°/5—10 mm. When heated with sulphuric acid it yields α -chloropropaldehyde; with carbamide or urethane it gives the same products as the dichloro-ether. One chlorine atom is removed by silver nitrate, showing that it occupies the α -position, and this is confirmed by its behaviour with pyridine, which yields a compound of which the *platinichloride* forms orange-yellow crystals, m. p. 187° has the composition

The constitution of the trichloro-ether follows from these reactions, from its modes of formation, and from its synthesis from β -chloropropaldehyde, allyl alcohol, and hydrogen chloride.

The *tetrachloro-n-propyl ether* obtained in the preparation of the trichloro-ether is a colourless, oily liquid, b. p. 157—162°/5—10 mm. With sulphuric acid and with silver nitrate, it behaves like the mono- and dichloro-ethers. It gives a pyridine compound, of which the *platinichloride*, $(C_3H_7OCl_2 \cdot C_5H_5N)_2PtCl_4$, forms orange-yellow crystals, m. p. 187°.

R. V. S.

Chloro ethers. VII. Aldehydic Condensations by means of Halogenated Ethers. GIUSEPPE ODDO and GUIDO CUSMANO (*Gazzetta*, 1911, 41, ii, 246—258. Compare preceding abstract).—Carbamide reacts with dichloroacetaldehyde or its polymeride in aqueous solution, yielding α -hydroxy- $\beta\beta$ -dichloroethylecarbamide, which forms crystals of prismatic crystals, m. p. 142° (decomp.). $\alpha\beta\beta$ -Trichloroethyl ether and carbamide in presence of sodium acetate yield the same condensation product.

Hydrazine hydrate reacts with dichloroacetaldehyde, with its polymeride, and with $\alpha\beta\beta$ -trichloroethyl ether, giving an amorphous, reddish-yellow powder, which does not melt at 300°.

Semicarbazide reacts with the same three ethers, yielding a substance, $C_4H_5O_2N_3$, which is an amorphous, yellowish-white powder.

Phenylhydrazine with dichloroacetaldehyde or $\alpha\beta\beta$ -trichloroethyl ether forms glyoxalosazone.

Carbamide and α -chloropropaldehyde yield a white, amorphous substance, m. p. 167—170° (decomp.), which is also formed when carbamide reacts with $\alpha\beta$ -dichloro-, $\alpha\beta\beta$ -trichloro-, or tetrachloro-*n*-propyl ether.

Urethane reacts with α -chloropropaldehyde, $\alpha\beta$ -dichloro-, $\alpha\beta\beta$ -trichloro- and tetrachloro-*n*-propyl ether, giving in all cases β -chloro-propylidenebisurethane, $CHMeCl \cdot CH(NH \cdot CO_2Et)_2$, which forms tufts of long, colourless needles, m. p. 122—123°.

Urethane and β -chloro- $\alpha\beta$ -dibromo-*n*-propyl ether yield β -chlorobromopropylidenebisurethane, $CMeClBr \cdot CH(NH \cdot CO_2Et)_2$, which crystallises in small, transparent prisms, m. p. 113—115°. The above chlorobromo-ether, when treated with carbamide, gives an aldehydic compound crystallising in minute needles, m. p. 183—184°.

R. V. S.

Catalytic Actions of Sulphuric Acid. I. GIUSEPPE ODDO (*Gazzetta*, 1911, 41, ii, 258—267. Compare preceding abstracts).—When the halogenated ethers and some related substances are dropped

on concentrated sulphuric acid at a high temperature, the corresponding aldehydes are formed.

[With EFISIO MAMELI.]—Dichloroacetaldehyde is obtained from any of the following substances when dropped on concentrated sulphuric acid at 140—145°: $\alpha\beta$ -trichloroethyl ether, dichloroacetaldehyde hydrate, dichloroacetal, and ethyl dichlorovinyl ether (compare Abstr., 1904, i, 280; Wohl and Roth, Abstr., 1907, i, 170).

[With GUIDO CUSMANG.]— α -Chloropropaldehyde is obtained by the action of concentrated sulphuric acid at 135—140° on the following substances: $\alpha\beta$ -dichloro-, $\alpha\beta\beta'$ -trichloro- and tetrachloro-*n*-propyl ether, di-*n*-propyl- β chloropropylidene ether, and *n*-propyl- β chloropropylene ether.

[With EUGENIA MANTOVANI.]—When ethyl acetoacetate is dropped on sulphuric acid at 155—165°, keten appears to be formed, but is resinified by the acid; at the same time much ethyl acetate is produced. The decomposition of ethyl malonate with sulphuric acid at 200° yields carbon dioxide, ethylene, and ethyl acetate. Ethyl succinate is not acted on below 240—250°, and is then merely hydrolysed, ethyl alcohol and succinic acid being obtained.

R. V. S.

Nitrogen and Sulphur Derivatives of Carbon Disulphide XVIII. Chlorothiicarbonates. MARCEL DELÉVINE (*Bull. Soc. chim.*, 1911, [iv], 9, 901—903. Compare Klason, Abstr., 1887, 1023).—The methyl, ethyl, and propyl esters have been prepared by Klason's method (*loc. cit.*) and are described.

The alcohol (2 mols.) is added gradually to thiocarbonyl chloride at atmospheric temperature, and after twelve to twenty-four hours ether is added, and finally water. The oily layer is separated, washed with water, dried over calcium chloride, and rectified by distillation over carbon dioxide. The yield of the methyl and ethyl esters is about 50% of the theoretical, but is very small in the case of the propyl ester. The esters are pale yellow liquids of pungent ozone-like odour, they fume in the air, owing to oxidation and the liberation of sulphuric acid; they are luminous in the dark, the propyl ester being less luminous. With amines they react according to the equation: $2R_1R_2NH + Cl-CS-OR' = R_1R_2N-CSOR' + R_1H_2NH, HCl$, where R_1 or R_2 may be a hydrogen atom. With secondary amines they give dialkylthiocarbamates (Abstr., 1910, i, 720).

Methyl chlorothiicarbonate, $CSCl-OMe$, has D_4^{20} 1.2975, D_4^{25} 1.2664 and b. p. 107—108°. *Ethyl chlorothiicarbonate* has D_4^{20} 1.2132, D_4^{25} 1.1955, b. p. 127—128° (compare Klason, *loc. cit.*). *Propyl chlorothiicarbonate*, $CS-Cl-OPr^3$, b. p. 148—151°, reacts with aniline to form propyl phenylthiocarbamate (Orndorff and Richmond, Abstr., 1909, i, 156), which is best obtained by Roschdestvensky's method (Abstr., 1909, i, 300).

T. A. H.

Some Compounds of Organic Salts of Bivalent Metals with Ammonia, Pyridine, and Phenylhydrazine. HERMANN GROSSMANN and GUSTAV JÄGER (*Zeitsch. anorg. Chem.*, 1911, 73, 48—74).—For the purpose of investigating the influence of the acid radical on the type of additive compound formed by salts (compare Grossmann

and Hänseler, Abstr., 1906, i, 7), the additive compounds of a number of salts of organic acids have been prepared. The ammonia compounds are usually prepared by dissolving the hydrated salt in 25% aqueous ammonia, filtering, and evaporating, first on a water-bath and then in a desiccator over sodium hydroxide in an atmosphere of ammonia.

Ammonia cupric formate, $\text{Cu}(\text{HCO}_2)_2 \cdot 3\text{NH}_3$, forms large, blue prisms or slender needles, m. p. 154° . The compound is stable in air, but is decomposed by water. *Ammonia cupric chloroacetate*,

forms a blue, crystalline powder, m. p. 180° (decomp.). *Ammonia cupric trichloroacetate*, $\text{Cu}(\text{CCl}_3\cdot\text{CO}_2)_2 \cdot 5\text{NH}_3$, forms dark bluish-violet crystals, which lose ammonia suddenly, becoming grass-green at 94° and melting at 98° . After six weeks in air the crystals contain 1NH_3 . *Ammonia zinc formate*, $\text{Zn}(\text{HCO}_2)_2 \cdot 2\frac{1}{2}\text{NH}_3$, forms colourless, prismatic needles, m. p. 126° . *Ammonia zinc acetate*,

forms colourless needles. *Ammonia cadmium formate*,

forms transparent crystals, m. p. 70° , and loses NH_3 and H_2O in air. *Ammonia cadmium acetate*, $\text{Cd}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 4\text{NH}_3$, forms transparent cubes, m. p. 141° , and loses NH_3 in air. *Ammonia nickel formate*, $\text{Ni}(\text{HCO}_2)_2 \cdot 3\text{NH}_3 \cdot 2\text{H}_2\text{O}$, is a bright blue, crystalline powder, becoming green at 120° and charring at 360° , three other additive compounds of the salt being also obtained, containing $4\text{NH}_3 \cdot 2\text{H}_2\text{O}$, $3\text{NH}_3 \cdot \text{H}_2\text{O}$, and 2NH_3 respectively. *Ammonia nickel acetate*, $\text{Ni}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{NH}_3$, is a green precipitate; a definite compound could not be obtained from the chloroacetate. *Ammonia nickel trichloroacetate*,

forms blue crystals, and becomes green in air, losing 2NH_3 and $3\text{H}_2\text{O}$.

Pyridine cupric formate, $\text{Cu}(\text{HCO}_2)_2 \cdot 3\text{C}_5\text{NH}_5$, forms blue needles, m. p. 103° , and loses pyridine in air. Two *pyridine cupric acetates* are obtained, $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 5\text{C}_5\text{NH}_5$ being bright green, and

dark violet. *Pyridine cupric chloroacetate*,

forms blue crystals, and a second compound is also obtained. *Pyridine cupric trichloroacetate*, $\text{Cu}(\text{CCl}_3\cdot\text{CO}_2)_2 \cdot 4\text{C}_5\text{NH}_5 \cdot 2\text{H}_2\text{O}$, forms sky-blue needles. *Pyridine zinc formate*, $\text{Zn}(\text{HCO}_2)_2 \cdot 2\text{C}_5\text{NH}_5$, loses pyridine in air, whilst zinc acetate yields only unstable products. *Pyridine cadmium formate*, $\text{Cd}(\text{HCO}_2)_2 \cdot 3\text{C}_5\text{NH}_5$, has m. p. 94° , and loses pyridine in air. *Pyridine nickel formate*, $\text{Ni}(\text{HCO}_2)_2 \cdot 3\text{C}_5\text{NH}_5$, is a pale green, crystalline powder, which blackens without melting; *pyridine cobalt formate*, $\text{Co}(\text{HCO}_2)_2 \cdot 3\text{C}_5\text{NH}_5$, is pale pink, and is stable in air, but loses pyridine after some months.

Phenylhydrazine zinc formate, $\text{Zn}(\text{HCO}_2)_2 \cdot 2\text{C}_6\text{H}_5\text{N}_2$, is a white solid, m. p. 110° , which rapidly darkens in air. *Phenylhydrazine cadmium formate*, $\text{Cd}(\text{HCO}_2)_2 \cdot \text{C}_6\text{H}_5\text{N}_2$, has m. p. 128° ; *phenylhydrazine nickel formate*, $\text{Ni}(\text{HCO}_2)_2 \cdot \text{C}_6\text{H}_5\text{N}_2 \cdot 3\text{H}_2\text{O}$, a bluish-green, amorphous mass, blackens without melting, a blue product being also obtained, probably containing $2\text{C}_6\text{H}_5\text{N}_2$. *Phenylhydrazine cobalt formate*, $\text{Co}(\text{HCO}_2)_2 \cdot 2\text{C}_6\text{H}_5\text{N}_2$,

is a pink substance, m. p. 170—172°, which darkens in air. *Phenylhydrazine cobalt acetate*, $\text{Co}(\text{C}_6\text{H}_5\text{O}_2)_2 \cdot 4\text{C}_6\text{H}_5\text{N}_2$ (compare *Moitron*, Abstr., 1897, i, 561), is unstable; *phenylhydrazine cobalt chloride acetate*, $\text{Co}(\text{CH}_3\text{ClCO}_2)_2 \cdot 3\text{C}_6\text{H}_5\text{N}_2$, and *phenylhydrazine cobalt triiodide acetate*, $\text{Co}(\text{CCl}_3\text{CO}_2)_2 \cdot 6\text{C}_6\text{H}_5\text{N}_2$, m. p. 188°, are pink solids. A tabular summary of the compounds of this series is given. C. H. D.

The Hydrates of Potassium Acetate, their Solubility and Transition Point. RYUJI ABE (*Mem. Coll. Sci. Eng. Kyoto*, 1911, 3, 211—215).—The solubility curve of potassium acetate in water has a single break at 41.3°, the stable phase at lower temperatures being $2\text{KC}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$, and at higher temperatures, $2\text{KC}_2\text{H}_3\text{O}_2 \cdot 11\text{H}_2\text{O}$. C. H. D.

Aliphatic Nitro-compounds. XI. α -Nitroisobutyric Acid. WILHELM STEINKOFF and ALEXANDER SUPAN (*Ber.*, 1911, 44, 2891—2897).— α -Nitroisobutyric acid has been prepared by the following series of operations: α -Hydroxylaminoisobutyronitrile, obtained by the addition of hydrogen cyanide to acetoxime, was oxidised with potassium permanganate in sulphuric acid to α -nitroisobutyronitrile (Piloty, Abstr., 1898, i, 616). This cannot be hydrolysed directly, but on heating with methyl alcohol and hydrochloric acid, it is converted almost quantitatively into the hydrochloride of nitroisobutyroiminomethyl ether,

This is decomposed by water into methyl α -nitroisobutyrate, $\text{NO}_2 \cdot \text{CMe}_2 \cdot \text{CO}_2\text{Me}$, a colourless oil, which with ammonia forms α -nitroisobutyramide, and when left for some days with concentrated hydrochloric acid is slowly hydrolysed to α -nitroisobutyric acid.

When the ammonium salt is treated with sodium nitrite and sulphuric acid, carbon dioxide is eliminated and a blue oil formed, which solidifies to colourless crystals of propyl ψ -nitrol,

α -Nitroisobutyric acid differs from nitroacetic and α -nitropropionic acids in not being hygroscopic. On prolonged keeping, it decomposes to a blue oil mixed with colourless crystals, which melt to a blue liquid, and nitrous acid is liberated. This is a nitroso-compound, but it has not at present been identified. When fused, α -nitroisobutyric acid liberates carbon dioxide and forms a colourless oil, which suddenly decomposes, becoming blue and solidifying to a colourless solid. Similar changes are noted on heating in solvents. Possibly the acid decomposes into *sec.*-*aci*-nitropropane, this into acetone and nitrosyl, which re-unite to a nitroso-alcohol, $\text{NO} \cdot \text{CMe}_2 \cdot \text{OH}$.

α -Nitroisobutyronitrile is an oil, b. p. 73°/12 mm. Methyl α -nitroisobutyric acid has b. p. 73—74°/12 mm. α -Nitroisobutyric acid forms crystals, m. p. 95°; the ammonium, sodium, and phenylhydrazine salts have been prepared. E. F. A.

Action of Hydrogen Chloride and Methyl Alcohol on Negatively Substituted Nitriles. WILHELM STEINKOFF and WIATCZESLAW MALINOWSKI (*Ber.*, 1911, 44, 2898—2904).—Whilst

Stainer has shown that, in general, both aromatic and aliphatic imino-ether hydrochlorides are obtained by the reaction of nitrile, alcohol, and hydrogen chloride. Steinkopf obtained trichloroacetamide from trichloroacetonitrile (Abstr., 1907, i, 488) and nitroacetamide from nitroacetonitrile (Abstr., 1909, i, 216), instead of the expected imino-ethers. On the other hand, Steinkopf and Supan (preceding abstract) find that α -nitroisobutyronitrile gives the normal imino-methyl ether and not the amide. The influence of the negative nitro-group appears to be less when the nitro-group is tertiary.

The behaviour of a number of halogen substituted acetonitriles towards methyl alcohol and hydrogen chloride has now been investigated. Chloro-, bromo- and iodo-acetonitrile give the normal imino-ether hydrochloride; dibromoacetonitrile yields a mixture of imino-ether and dibromoacetamide.

Trichloro-, trichloro-, dichloronitro-, and tribromo-acetonitrile all yield the corresponding amides, no trace of imino-ether being formed.

The primary nitro-group is as active as two or three chlorine atoms; this is probably owing to its reacting in the aci-form.

With trichloroacetonitrile and dimethylethylcarbinol only the corresponding amide was obtained. The imino-ether could not be obtained on boiling tribromoacetonitrile with methyl alcohol.

[With ALEXANDER SUPAN.]— ω -Nitrophenylacetonitrile was obtained pure in colourless crystals, m. p. 39–40°, from the sodium salt (Wieland, Abstr., 1902, i, 541).

E. F. A.

Oxidation of Hexoic and Heptoic Acids by Dilute Permanganate Solutions. E. S. PRSCHEVALSKY (*J. Russ. Phys. Chem. Soc.*, 1911, 43, 1000–1006).—Oxidation of *n*-hexoic acid with 1% neutral permanganate solution in the cold yields butyric, valeric, oxalic, and succinic acids.

Under similar conditions, *n*-heptoic acid gives oxalic, succinic, propionic, butyric, and valeric acids; further, the action of semicarbazide hydrochloride on that portion of the oxidation products which dissolves readily in ether, water, alcohol, chloroform, and acetone yields two isomeric semicarbazones, $C_8H_{11}O_3N_3$, one, m. p. 138–140°, readily soluble, and the other, m. p. 176°, slightly soluble. These represent semicarbazones of a keto-acid, $C_8H_{12}O_3$, which must be regarded as an intermediate product in the oxidation of *n*-heptoic acid.

T. H. P.

Preparation of Diglycollic Acid Esters of Phenols and Phenolic Derivatives. O. F. BOENRINGER & SOUSE (D.R.-P. 236045).—Phenolic esters of diglycollic acid prepared from the acid dichloride have been described (Abstr., 1910, i, 732); it is now found that this reaction proceeds smoothly with the acid on gently warming in the presence of phosphorus pentachloride and an indifferent base, the phenyl ester being thus obtained in 90% yield. The *o*-tolyl ester has m. p. 100–101°.

F. M. G. M.

Studies on Tautomerism. VI. Colorimetric Method for the Estimation of Enols in Allelotropic Mixtures. *Levene, Knorr and H. Schubert (Ber., 1911, 44, 2772-2778. Compare Wislicenus, Abstr., 1900, i, 9, 597).*—By colorimetric comparison of the solutions obtained on adding ferric chloride to equilibrium mixtures of tautomeric substances, the amount of enolic form present can be estimated. The maximum coloration is produced when 1 mol. of ferric chloride reacts with the enol, the corresponding equation being $RH + FeCl_3 = FeRCl_2 + HCl$, where R is the enolic residue. Standard solutions of three kinds are employed: (1) when the pure enolic form is available, a solution of it containing an equimolecular quantity of sublimed ferric chloride; (2) solutions of the iron salt of the type FeR_2 (see below), to which 2 mols. of ferric chloride have been added ($FeR_2 + 2FeCl_3 = 3FeRCl_2$), and in addition, to make them identical with those of the first type, 3 mols. of hydrochloric acid; (3) solutions (usually alcoholic) of equilibrium mixtures to which 1 mol. of ferric chloride has been added, the amount of the enolic form present having been determined by comparison with test solutions of one of the first two types. The standard solutions of the third kind often remain unaltered for months. The solutions of types I. and II. also suffer no marked alteration on keeping, unless (as in the case of dibenzoylacetyl methane, for instance) decomposition occurs; hence the enolic forms may be fixed in the form of their iron salts. In some cases (ethyl acetoacetate and especially ethyl benzoylacetate) the addition of hydrochloric acid to the iron salts lessens the intensity of colour of the solution; in other cases (tribenzoyl methane) no change is observed. The standard solutions of the second type have exactly the same degree of coloration as those of type I.

The method has been employed for the study of the diacetylacetic ester, mesityl-oxide-oxalic esters, and Claisen's triketones. In the present paper experimental data are given in the case of methyl mesityl-oxide-oxalate. In the fused state at 98° the enolic ester reaches equilibrium (4% enol) after twenty-five hours, whilst the ketonic ester attains to the same equilibrium in two hundred hours. In absolute alcoholic solution at 78° equilibrium is reached (3.7% enol) after twelve days, whilst the ketonic form contains 3.9% enol after twenty days. In absolute alcohol at room temperature, the enolic ester is converted into the equilibrium mixture (4% enol) after eight weeks. Determinations were also made of the equilibria reached in different solvents after fourteen days at 80° .

Some new iron salts have been prepared (compare Hantzsch and Desch, Abstr., 1902, i, 708; also this vol., i, 976). *Ethyl ferriacetoacetate*, $Fe(C_8H_7O_3)_3$ (from an alcoholic solution of ethyl sodioacetoacetate and an ethereal solution of ferric chloride), forms small compact, red crystals, m. p. $99-100^\circ$. The solutions of the salt are orange-coloured, and become cherry-red on addition of ferric chloride.

Ethyl ferriformylphenylacetate, $Fe(C_{11}H_{11}O_3)_3$, is obtained in a crystalline condition by treating an ethereal solution of the ester with

an alcoholic solution of sodium ethoxide and ferric chloride in the presence of sodium acetate.

R. V. S.

Lactarinic Acid. J. BOUSVULT and CHARLES CHARAUX (*Compt. rend.*, 1911, 153, 880—881. Compare this vol., i, 835).—Lactarinic acid is identical with *ε-ketostearic acid*,

since it undergoes the Beckmann transformation, giving rise to two compounds, $\text{CH}_2\cdot[\text{CH}_2]_{11}\cdot\text{NH}\cdot\text{CO}\cdot[\text{CH}_2]_4\cdot\text{CO}_2\text{H}$ and $\text{CH}_2\cdot[\text{CH}_2]_{11}\cdot\text{CO}\cdot\text{NH}\cdot[\text{CH}_2]_4\cdot\text{CO}_2\text{H}$.

These were not isolated, but recognised by the products obtained on hydrolysis.

W. O. W.

Synthesis of Fumaric and Maleic Acids from the Acetylene Diiodides. EDWARD H. KEISER and LE ROY McMASTER (*Amer. Chem. J.*, 1911, 46, 518—523).—Keiser (Abstr., 1890, 594) has shown that fumaric acid can be produced by the action of potassium cyanide and potassium hydroxide on solid acetylene di-iodide. The same author (Abstr., 1899, i, 398) has also obtained a liquid form of acetylene di-iodide, which he regarded as the *cis*- or maleic form, whilst the solid compound was regarded as the *trans*- or fumaric isomeride.

This view has now been confirmed, and experiments are described which show conclusively that the solid iodide can be converted into fumaric acid and the liquid isomeride into maleic acid.

E. G.

Nitrile of Fumaric Acid. EDWARD H. KEISER and J. J. KESSLER (*Amer. Chem. J.*, 1911, 46, 523—528).—Keiser (Abstr., 1890, 594) and Keiser and McMaster (preceding abstract) have shown that fumaric and maleic acids can be prepared by treating the solid and liquid forms of acetylene di-iodide respectively with potassium cyanide and hydroxide. It is evident that in these syntheses the nitrilos of the acids must be formed, but they could not be isolated.

Attempts have therefore been made to prepare the nitriles by heating fumaramide and ammonium maleate with phosphoric oxide. Fumaronitrile has been produced in this way, but maleonitrile could not be obtained.

Fumaramide is prepared (1) by treating ethyl bromosuccinate with dilute ammonia, and (2) by the action of 50% ammonia solution on dimethyl fumarate. When an intimate mixture of fumaramide and phosphoric oxide is heated on a sand-bath at about 120°, *fumaronitrile*, m. p. 96°, b. p. 186°/760 mm., is obtained as a sublimate of slender needles. The nitrile has a pleasant, pungent odour, sublimes readily even below 100°, and is decomposed by alkali hydroxide with formation of alkali cyanide.

E. G.

Hydrogenation of Crotonaldehyde in Presence of Nickel. ROGER DOUBIS (*Bull. Soc. chim.*, 1911, [iv], 9, 922—925).—On reduction by Sabatier and Senderens' method (Abstr., 1905, i, 333), crotonaldehyde furnishes butyraldehyde and butyl alcohol with a small quantity of a syrupy substance, b. p. 115—119°/18 mm., which may contain an octyl alcohol.

n-Butylidenediacetate, $\text{CHPr}(\text{NH}\cdot\text{CO}_2\text{Et})_2$, m. p. 130°, obtained by condensing butyraldehyde with urethane in presence of hydrochloric acid, crystallises in rosettes of colourless needles. *n*-Butyl phenylthiocarbamate, $\text{NHPh}\cdot\text{CS}\cdot\text{O}\cdot\text{C}_4\text{H}_9$, m. p. 53°, obtained by Roschdestvensky's method (Abstr., 1910, i, 107) or by the action of phenylthiocarbimide on *n*-butyl alcohol in presence of sodium hydroxide, crystallises in long, colourless needles. T. A. H.

Ethylation of Acetone. ERNST ZERNER (*Monatsh.*, 1911, 32, 677—686).—By the action of sodamide and halogen alkyls on ketones, alkyl derivatives of these are obtained. Haller and Bauer (Abstr., 1909, i, 108) have thus prepared methyl and mixed methyl ethyl derivatives of acetone. Acetone itself yields only condensation products, particularly isophorone, when treated with sodamide and ethyl bromide. Accordingly, dipropyl ketone was used as the starting point for the preparation of ethyl derivatives of acetone. In etheral solution no action takes place, but in benzene prolonged boiling suffices to cause interaction. About half of the dipropyl ketone is recovered unchanged, and the operation has to be repeated several times. Oxime products are not formed in any quantity, and the ketones are separated and purified by fractional distillation. The process is repeated in order to pass to the more alkylated ketones.

The ethylacetones described do not mix with water and have a camphor-like odour; only hexaethylacetone resembles the fruity odour of dipropyl ketone. The corresponding alcohols have a sharp peppermint-like odour.

Triethylacetone [γ -ethylheptane- δ -one], perhaps already obtained by Geuther and Frölich (Abstr., 1880, 622), has b. p. 174.5—175.5°, 741 mm. On reduction it yields triethylisopropyl alcohol [γ -ethylheptane- δ -ol], which has b. p. 80—81°/10 mm. The oxime obtained by heating the ketone with Crismer's salt formed slender needles, m. p. 90—91°.

sym-Tetraethylacetone [γ -diethylheptane- δ -one] has b. p. 206—207.5°/771 mm. (Herzig and Zeisel, Abstr., 1894, i, 74). It does not form an oxime or phenylhydrazone. Tetraethylisopropyl alcohol [γ -diethylheptane- δ -ol], obtained on reduction, has b. p. 99—101°/13 mm.; it reacts with phenylcarbimide, forming the phenylurethane, m. p. 72—73°.

Pentaethylacetone [γ -triethylheptane- δ -one] has b. p. 237.5—238.5°, 761 mm.; pentaethylisopropyl alcohol [γ -triethylheptane- δ -ol] has b. p. 125—127°/18 mm., and forms a phenylurethane, m. p. 71—72°. The mixture of the phenylurethane with that of the γ -diethylheptane- δ -ol shows a depression of 18° in the m. p.

Hexaethylacetone [γ -tetraethylheptane- δ -one] has b. p. 274—275°, 759 mm., and crystallises in plates, m. p. 44°. The corresponding hexaethylisopropyl alcohol [γ -tetraethylheptane- δ -ol] has b. p. 159—161°/18 mm. The phenylurethane forms a butter-like substance, which is not characteristic. E. F. A.

An Intermediate Product of Alcoholic Fermentation. HAS VON EULER and A. FODOR (*Biochem. Zeitsch.*, 1911, 36, 401—410).—The authors fail to confirm Boyson-Jensen's statement that dihydroxy-

ketone can be isolated as an intermediate product of fermentation by yeast. They describe their method for preparing hexosephosphoric acid ester, and their results obtained with this substance agree in the main with those of Harden and Young. They have found indications that in addition to the hexosediphosphoric acid, a triosemonophosphoric acid is also formed (compare Young, *Abstr.*, 1910, i, 12; Lebedeff, *ibid.*, 716; this vol., i, 837). S. B. S.

Decomposition of Dextrose by Dilute Sulphuric Acid. HERMANN OST and TH. BRODTKORB (*Chem. Zeit.*, 1911, 35, 1125—1126, compare Ost and Wilkening, *Abstr.*, 1910, i, 364).—Dextrose is converted by dilute sulphuric acid under pressure at high temperatures chiefly into humin substances, formic acid, and levulic acid; for example, about 8% of the dextrose is destroyed by heating a 5% solution of the sugar with a 2% solution of sulphuric acid for twenty-four hours at 100°, whilst 100 grams of dextrose heated with 2% sulphuric acid at 140° for seven hours yield about 16 grams of formic acid, 32 grams of levulic acid, and 13 grams of humin substances. W. H. G.

The Behaviour of Invert Sugar in Alkaline Solution in Presence of Hydrogen Peroxide. ADOLF JOLLES (*Biochem. Zeitsch.*, 1911, 36, 389—393).—In following the polarisation changes when invert sugar is treated with hydrogen peroxide in alkaline solutions, it is found that the rotation sinks gradually to 0°, then becomes dextrorotatory, the dextrorotation then reaches a maximum, and again decreases. The explanation of this result is that levulose is more readily oxidised than dextrose, and is more rapidly destroyed. S. B. S.

Mirror Image Isomerism with Chromium Compounds. I. ALFRED WERNER (*Ber.*, 1911, 44, 3132—3140).—The author has succeeded in resolving salts of the 1:2-dichlorodiethylenediaminechromium series into their optical isomerides, in accordance with the configurations:

These salts present a case of molecular asymmetry I, similar to that observed with the 1:2-dinitrodiethylenediaminecobalt salts (this vol., i, 838). Owing to the fact that the aqueous solutions of these salts are not very stable, readily giving chloro-aquo- and diaquo-salts, their resolution with silver bromocamphorsulphonate did not afford much hope of success. It was found, however, that when *d*-ammonium α -bromocamphorsulphonate was added to a freshly-prepared saturated solution of 1:2-dichlorodiethylenediaminechromic chloride, violet crystals of 1:2-dichlorodiethylenediaminechromic *d*- α -bromocamphorsulphonate were deposited after a short time in a pure condition. From the

mother liquor, any racemate could then be precipitated as dithionates and then, on the addition of potassium platinochloride, the dithionates obtained as the platinochloride, from which the nitrate could be prepared by decomposition with silver nitrate. Similar results were obtained with *l*-ammonium α -bromocamphorsulphonate, *d*-dichlorodiethylenediaminechromic *l*- α -bromocamphorsulphonate being first deposited.

It is noteworthy that the *l*-dichloro-salts and *d*-bromocamphorsulphonic acid, and the *d*-dichloro-salts and *l*-bromocamphorsulphonic acid, give the least soluble salts, which is the opposite to what was observed with the cobalt salts.

The active salts are not different in colour from the inactive, but the active chlorides and dithionates are more soluble than the corresponding racemates.

The optical rotation observed are as follows (I):

I.		II.	
	$[\alpha]$.	$[\alpha]$.	$[\alpha]$.
Chloride	-140°	-415.1°	-182°
	+140	+415.1	+184
Bromide	-130	+419.9	-178
	+124	+400.5	+168
Iodide	-120	-366	-164
	+122	+372	+164

They are much less than those of the corresponding dichlorodiethylenediaminecobalt salts (II.) (details are to be given later).

Racemisation takes place rapidly in aqueous solution, being complete at 0° after three hours in a 0.5% solution; in hydrochloric acid solution the velocity of racemisation is much slower, and at the same time the rotation of the chloride is much diminished.

Racemic 1:2-dichlorodiethylenediaminechromic chloride, $[\text{C}_2\text{H}_4\text{Cr en}_2]\text{Cl}$, is best prepared as follows: Potassium chromium oxalate,

is heated with a 10% solution of ethylenediamine until a red salt begins to deposit from the dark violet solution. After cooling, the salt, which has the formula $[\text{C}_2\text{O}_4\text{Cr en}_2][(\text{C}_2\text{O}_4)_2\text{Cr en}]$, is collected, well washed with cold water, rubbed into a paste with concentrated hydrochloric acid, and kept until a portion when dried on a porous plate leaves a yellow residue of oxalatodiethylenediaminechromic chloride, $[\text{C}_2\text{O}_4\text{Cr en}_2]\text{Cl}$. This is collected and carefully heated with concentrated hydrochloric acid until solution is complete. The cherry red solution so obtained is put into a crystallising dish, and alcohol added gradually, with vigorous stirring, until a violet salt begins to deposit. On keeping, a thick, violet paste of the required racemate is formed, which is well washed with alcohol and ether to remove oxalic acid, and may then be used for the resolution.

l-Dichlorodiethylenediaminechromic *d*-bromocamphorsulphonate,

forms small, shining, violet crystals, and has $[\alpha] = -35^\circ$, $[\text{M}] = -193.55^\circ$. The corresponding *d*-*l*-salt has $[\alpha] = +32^\circ$, and $[\text{M}] = +176.9^\circ$. The solutions rapidly undergo racemisation. The active 1:2-dichlorodiethylenediaminechromic chlorides, $[\text{Cl}_2\text{Cr en}_2]\text{Cl}$, H_2O ,

re obtained from the bromocamphorsulphonates by treatment with concentrated hydrochloric acid; they form small, violet needles. The *nitrites*, $[(C_2Cr en_2)Br]$, were prepared from the chlorides and hydrochloric acid, and crystallise in small, reddish-violet needles. The *nitrate*, $[(C_2Cr en_2)NO_3]$, were obtained from the chlorides and nitric acid as violet, crystalline powders.

T. S. P.

Chemico-Crystallographic Examination of the Platinichlorides, Platinibromides, Stannichlorides, and Stannibromides of Quaternary Ammonium Bases. A. RISS (*Zeitsch. Krist. Min.*, 1911, 49, 513—617).—The quaternary ammonium bases, results of which have been examined, are those containing the groups $(Me_4, NMe_3Et, NMe_2Pr^A, NMe_2Pr^B, NMe_2Et_2, NMeEt_3, NMe_3 \cdot C_4H_9, Me_2CH, Pr^A, NMe_2EtPr^A, NEt_3, NMe_3 \cdot CH_2 \cdot CHMeEt, NMe_3 \cdot CH_2 \cdot CH_2Pr^A,$

$MeEtPr^A, NMe_2Pr^A, NEt_2Pr^A, NMeEtPr^A, NMePr^A, NEtPr^A, Et_2CH, NEt \cdot CH_2Pr^A, NMeEtPr^A \cdot CH_2Pr^A, NEtPr^A, NPr^A, Pr^A \cdot CH_2Pr^A, NMe(CH_2Pr^A)_2, NEt(CH_2Pr^A)_2, NPr^A(CH_2Pr^A)_2,$ and $(CH_2Pr^A)_3$. The crystallographic properties of the platinichlorides and bromides, and stanni-chlorides and -bromides of these bases are described; their m. p.'s or points of decomposition are stated; in many cases the densities of the several modifications of any one salt have been determined by the floating method in acetylene tetrabromide and toluene, and the transition temperatures of the modifications have been ascertained.

After a detailed comparison of the preceding physical constants, the author states the following generalisations:

(1) The m. p.'s decrease, and the transition temperatures (of the several modifications) increase, as the molecular weights of the tetra-alkylammonium platinichlorides increase.

(2) In the case of two isomeric salts, the one containing one or more alkyl groups has a lower m. p. and a higher transition temperature (for corresponding modifications) than that containing normal alkyl groups.

(3) The temperatures, at which the corresponding point systems of two or more isomeric and metameric salts undergo transition into a more highly symmetric analogous point systems, are higher the more is the symmetry of the molecule corresponding with the point system.

(4) The region of stability of the different modifications is dependent on the molecular weight and the symmetry of the molecule.

Experiments on the morphotropic relations of the salts with regard to their topic axis show that the platinichloride, platinibromide, and stannichloride of a given tetra-alkylammonium base form isomorphous mixtures in all proportions.

An outstanding feature of the author's experiments is the regular shifting at high temperatures of the region of stability of the polymorphous modifications of members of homologous series. The paper concludes with a discussion of the question whether this regularity is characteristic of all salts of members of the families in the periodic table. A consideration of the transition temperatures of the modifi-

cations of the nitrates of the alkali metals, of the halides of mercury of the carbonates of the magnesium-barium group and so forth indicates that the answer to the question is in the affirmative.

C. A.

Methylated Polypeptides. Betaine of Diglycylglycine. EMIL ABDERHALDEN and KARL KAUTZSCH (*Zeitsch. physiol. Chem.*, 1911, 75, 19—29. Compare this vol., i, 528).—Trimethylglycylglycine, $\text{OH}\cdot\text{NMe}_3\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ or

obtained from chloroacetylglycylglycine and trimethylamine, is isolated in the form of the *platinichloride*, which forms orange-yellow, prismatic crystals, m. p. 181° (corr., decomp.).

The *ethyl ester*, prepared by decomposition of the *platinichloride* with hydrogen sulphide and treatment of the hydrogen chloride of the base with ethyl alcohol and hydrogen chloride, yields a *platinichloride*, crystallising in slender, lustrous, bright orange-yellow plates. The *platinichloride* of the corresponding *methyl ester*, prepared in the same way, crystallises in six-sided prisms, m. p. 180° . Analysis showed it to be partly hydrolytically decomposed. When prepared by dissolving the *platinichloride* of the base in methyl alcohol and saturating with dry hydrogen chloride, it was obtained in yellow needles, m. p. $215.5\text{--}216.5^\circ$ (corr., decomp.).

Trimethylglycylglycine when hydrolysed with boiling concentrated hydrochloric acid for fifteen hours gives betaine hydrochloride and glycine hydrochloride, the resolution being complete. Trimethyl-*dl*-leucylglycine when boiled for two hours with fuming hydrochloric acid is recovered almost unchanged.

Hydrolysis leading to the formation of betaine took place on attempting to methylate chloroacetylalanine with trimethylamine, and a similar behaviour was shown by chloroacetyl-*l*-tyrosine. Betaine was obtained further on attempting to methylate glycylglycine with methyl iodide. When attempting to methylate polypeptides with methyl iodide and potassium hydroxide, products containing iodine and potassium were usually obtained; these probably represent potassium iodide additive products.

E. F. A.

Preparation of Iodo-fatty Acid Compounds and their Behaviour in the Animal. EMIL ABDERHALDEN and PAUL HILKE (and M. GUGGENHEIM) (*Zeitsch. physiol. Chem.*, 1911, 75, 38—50).—Iodoacetylglycine, $\text{CH}_2\text{I}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, prepared by the reaction of glycine with iodoacetyl chloride in *N*-sodium hydroxide, sinters at 130° , and begins to melt at 142° , m. p. 160° , decomp. 165° .

dl-*a*-Iodopropionylglycine, $\text{CHMeI}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, from glycine and *a*-iodopropionyl chloride, sinters and begins to melt at 60° , m. p. 80° , decomp. 135° . The *ethyl ester* crystallises in needles, which sinter at 45° , m. p. 60° , and give up iodine at 225° . *dl*-*a*-Iodopropionyl-*dl*-alanine, $\text{CHMeI}\cdot\text{CO}\cdot\text{NH}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$, crystallises in needles, which sinter at 155° , m. p. $180\text{--}190^\circ$, decomp. 194° . The *ethyl ester* forms yellow needles, which sinter at 50° , m. p. $52\text{--}60^\circ$, decomp. 234° with liberation of iodine.

Di-iodoelaidyl chloride, $C_{17}H_{33}I_2 \cdot COCl$, is obtained as a brownish-red mass by the action of thionyl chloride on di-iodoelaidic acid. With glycine, *di-iodoelaidylglycine*, $C_{17}H_{33}I_2 \cdot CO \cdot NH \cdot CH_2 \cdot CO_2H$, is obtained. The amorphous, colourless product sinters at 52° , m. p. 57° . The ethyl ester, prepared by interaction of the chloride with glycine ester, is crystalline, m. p. 82° , after sintering at 70° . *Di-iodoelaidylalanine* sinters at 54° , m. p. 64° ; it has $[\alpha]_D^{25} - 4.9^\circ$. The corresponding ester was only obtained as a syrup.

Di-iodoelaidyl-di-iodotyrosine,
 $C_{17}H_{33}I_2 \cdot CO \cdot NH \cdot CH(CH_2 \cdot C_6H_4 \cdot I_2 \cdot OH) \cdot CO_2H$,
 sinters at 92° , m. p. 170° .

Iodobenzoyl chloride, $C_7H_5I \cdot COCl$, from iodobenzoic acid and thionyl chloride, could not be distilled. It couples readily with amino-acids. *Iodobenzoylglycine* is an amorphous, faintly yellow-coloured, fatty mass; it sinters at 50° , m. p. 70° , decomp. $170-180^\circ$.

Ethyl di-iodobromide (lipiodin), $C_{17}H_{33}I_2 \cdot CH_2 \cdot CH_2 \cdot C_{11}H_{23} \cdot CO_2Et$, sinters at 32° , m. p. 40° , decomp. $220-230^\circ$, liberating iodine.

The physiological experiments indicate that iodine administered as di-iodoelaidic acid is slowly but completely excreted. The iodine of di-iodoelaidylglycine was in ten days only 50% excreted. The resorption was complete, but in the case of the ethyl ester it was less complete. Most of the iodine is in the faeces; in some experiments none was present in the urine.

Di-iodo-*L*-tyrosine and di-iodoelaidyl-*L*-tyrosine are badly resorbed; ethyl di-iodobromide is better resorbed. E. F. A.

α -Aminobutyric Acid. EMIL ABDERHALDEN (*Zeitsch. physiol.*, 1911, 74, 509-510).—Polemical. Koelker (this vol., i, 773) has not mentioned that Abderhalden, Chang, and Wurm (this vol., i, 526) have previously studied the behaviour of *DL*- α -aminobutyric acid towards yeast. E. F. A.

Alkylation of Commercial Cyanamide Salts. WILHELM TRAUBE and ALFRED ENGELHARDT (*Ber.*, 1911, 44, 3149-3152. Compare Traube and Wedelstaedt, *Abstr.*, 1900, i, 389).—The relatively pure disodium cyanamide, and likewise the crude commercial sodium cyanamide, react very readily with halogen alkyl and with alkyl sulphate in presence of water or alcohol, forming disubstituted cyanamides. These are converted into secondary amines without difficulty, and it is easy to separate the ammonia formed at the same time. This affords a very convenient method of preparing secondary amines in quantity. Dimethyl-, diethyl-, di-*iso*-amyl-, and dibenzyl cyanamide have been prepared in the manner described: from calcium cyanamide and methyl sulphate, 70-80% of the theoretical quantity of dimethylamine is obtained. Dimethylcyanamide has b. p. 163.5° (corr.); diethylcyanamide, b. p. $78^\circ/16$ mm.; di-*iso*-amylcyanamide, b. p. $84-14$ mm.; dibenzylcyanamide forms transparent, rhombic plates, m. p. 53.5° (corr.). E. F. A.

Acylation and Alkylation of Cyanamide. OTTO DIELS and RICHARD GOLLMANN (*Ber.*, 1911, 44, 3158-3165).—Cyanamide can

be acylated with ethyl chlorocarboxylate by the Schotten-Baumann method without difficulty, ethyl cyaniminodicarboxylate,

being formed. With phosphoric oxide, the formation of cyanos cyanate [carbimidonitrile] was expected; actually carbethoxyl cyanate [ethyl carbimidecarboxylate], $\text{CO}\cdot\text{N}\cdot\text{CO}_2\text{Et}$, is formed, identical with the substance prepared by Diels and Wolf (Abstr., 1906, i, 237) by the action of phosphoric oxide on ethyl nitrogen tricarboxylate.

Ammonia converts the diacylated cyanamide into the crystalline ammonium salt of the monoacyl compound, $\text{NC}\cdot\text{N}(\text{NH}_4)\cdot\text{CO}_2\text{Et}$. Dilute acids form ethyl allophanate; concentrated acids cause the addition of water and the formation of ethyl *as*-carbamidedicarboxylate,

By the interaction of methyl sulphate and cyanamide, the *normal* methylcyanamide initially formed is polymerised to *isotrimethyl melamine*, $\text{NH}\langle\begin{smallmatrix} \text{C}(\text{NMe})\cdot\text{NH} \\ \text{C}(\text{NMe})\cdot\text{NH} \end{smallmatrix}\rangle\text{C}\cdot\text{NMe}$, but dimethylcyanamide is very readily obtained in this manner. It is easily converted into dimethylcarbamide.

Ethyl cyaniminodicarboxylate, $\text{NC}\cdot\text{N}(\text{CO}_2\text{Et})_2$, forms large lustrous, silky prisms, with a burning taste, m. p. 33 (Harner, Abstr., 1878, 214).

Methyl cyaniminodicarboxylate, $\text{NC}\cdot\text{N}(\text{CO}_2\text{Me})_2$, crystallises as lustrous, octahedra, m. p. 96—97°.

Ethyl carbimidecarboxylate (Diels and Wolf, *loc. cit.*) is a transparent, mobile liquid, b. p. 115—116°/781 mm.

Methyl carbimidecarboxylate, $\text{CO}\cdot\text{N}\cdot\text{CO}_2\text{Me}$, is a transparent, mobile liquid of intensely biting odour, b. p. 97—98°; it decomposes on keeping to a colourless, crystalline compound, probably a polymeride.

Methyl phenylallophanate, $\text{NHPh}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}_2\text{Me}$, prepared by the interaction of methyl carhamidecarboxylate with aniline, crystallises in long needles, m. p. 143—144°.

The ammonium salt of ethyl cyaniminocarboxylate,

forms lustrous, compact, octahedral crystals, m. p. 107—108°.

Ethyl *as*-carbamidedicarboxylate, $\text{NH}_2\cdot\text{CO}\cdot\text{N}(\text{CO}_2\text{Et})_2$, crystallises as lustrous prisms, m. p. 86—87°, of faintly sweet taste. The corresponding methyl ester separates in slender, colourless needles, m. p. 137—138° (decomp.).

Dimethylcyanamide has b. p. 52°/14 mm.

as-Dimethylcarbamide, $\text{NH}_2\cdot\text{CO}\cdot\text{NMe}_2$, forms large, compact, lustrous prisms, m. p. 181—182°; it tastes sweet. E. F. A.

Synthesis of δ -Guanidinovaleic Acid. DANKWART ACKERMANN, R. ENGELAND, and FRIEDRICH KUTSCHER (*Zeitsch. Biol.*, 1911, 57, 179—182).— δ -Aminovaleic acid and cyanamide were set aside in a concentrated aqueous solution for some weeks, when a crystalline crust of δ -guanidinovaleic acid, $\text{CO}_2\text{H}\cdot[\text{CH}_2]_4\cdot\text{NH}\cdot\text{C}(\text{NH}_2)\cdot\text{NH}_2$, separated. This forms short, stunted, hard crystals, m. p. 265—266°, after previously becoming brown and sintering. When evaporated

with concentrated hydrochloric acid, the *chloride* is obtained in long, silicious needles, m. p. 170—171°. The *aurichloride* forms broad, silicious plates, m. p. 120—122°. The *platinichloride* is very soluble and not characteristic.
E. F. A.

Hypobromous [Acid and] Amides. ÉTIENNE BOISMENU (*Compt. rend.*, 1911, 153, 678—680. Compare François, *Abstr.*, 1909, i, 13, 490).—A description of the preparation of certain bromo-amides by the action of hypobromous acid on the amides.

Bromoformamide, $\text{H}\cdot\text{CO}\cdot\text{NHBr}$, is best prepared by the action of bromine on a solution of formamide in ethyl acetate in presence of silver oxide. It is thus obtained in crystals, m. p. 87—88° (decomp.).
W. O. W.

A New Derivative of Carbamide, Chlorocarbamide. AUGUSTE SEHAL and A. DETREUF (*Compt. rend.*, 1911, 153, 681—683. Compare Pattaway, *Trans.*, 1909, 95, 464).—Carbamide absorbs chlorine at 15°, forming a mixture of monochlorocarbamide and carbamide hydrochloride. The former may be isolated in a state of purity by adding carbamide (60 grams) to water (13 grams), cooling in ice, and passing chlorine until the weight increases by 32 grams. The clear liquid is cooled in methyl chloride for thirty minutes, the chlorocarbamide filtered in a vacuum, and washed with a previously prepared solution of the same substance.

Chlorocarbamide, $\text{NH}_2\cdot\text{CO}\cdot\text{NHCl}$, occurs in crystals, m. p. 71° (decomp.). It is soluble in five parts of water at the ordinary temperature, giving a neutral solution which slowly loses nitrogen, at the same time becoming acid and forming biuret. The substance behaves towards saturated organic compounds as a chlorinating or as an oxidising agent, or sometimes as hypochlorous acid, forming additive compounds. With unsaturated substances, it effects addition of hypochlorous acid or of chlorocarbamide, but sometimes brings about oxidation. The reactions are progressive, and their course can be followed by titration.
W. O. W.

Ethyl Azodicarboxylate. OTTO DIELS and PAUL FREITZSCHE (*Ber.* 1911, 44, 3018—3027).—Ethyl azodicarboxylate reacts normally with piperidine in cold petroleum, yielding the *dipiperidide*,

m. p. 134—135° (decomp.), golden-yellow prisms, but forms with aniline an additive compound, $\text{C}_{12}\text{H}_{17}\text{O}_4\text{N}_3$, m. p. 138°, of unknown constitution, although probably it is a hydrazine derivative, since it crystallises in colourless plates and prisms. A similar colourless compound, $\text{C}_{14}\text{H}_{21}\text{O}_4\text{N}_3$, m. p. 75—76°, is obtained with dimethyl-aniline.

Acting as a mild oxidising agent in consequence of its tendency to yield ethyl hydrazinedicarboxylate, ethyl azodicarboxylate very smoothly converts quinol into *p*-benzoquinone.

Reacting in methyl-alcoholic solution at 0°, hydrazine hydrate and methyl chlorocarbonate yield hydrazine hydrochloride and *methyl hydrazinecarboxylate hydrochloride*, $\text{CO}_2\text{Me}\cdot\text{NH}\cdot\text{NH}_2\cdot\text{HCl}$, m. p. 160°.

The base, $C_7H_9O_2N_3$, m. p. 63° , b. p. $108^\circ/12$ mm, colourless prisms, has a faint, alkaline reaction, is volatile with steam, yields a benzoylamine derivative, $CO_2Me \cdot NH \cdot N : CHPh$, m. p. 146° , and with aqueous potassium cyanate at 0° the semicarbazide, $CO_2Me \cdot NH \cdot NH \cdot CO \cdot NH_2$, m. p. $169-170^\circ$, and reacts with methyl chlorocarbonate in ether to form methyl hydrazinedicarboxylate, $CO_2Me \cdot NH \cdot NH \cdot CO_2Me$, m. p. 131° . This ester, which is very stable and resists the attack of strong acids or bases, is also formed by the action of warm aqueous potassium hydrosulphide on methyl hydrazinedicarboxylate hydrochloride. Methyl azodicarboxylate, $N_2[CO_2Me]_2$, b. p. $96^\circ/25$ mm., is prepared by the action of fuming nitric acid on methyl hydrazinedicarboxylate in nitric acid, D 14, at 0° , and behaves like the ethyl ester.

C. S.

Dehydrogenation by Catalysis. NICOLAI D. ZELINSKY (*Per.* 1911, 44, 3121-3125; *J. Russ. Phys. Chem. Soc.*, 1911, 43, 1220-1222).—Heated palladium black, prepared by reducing ammonium palladochloride by means of formic acid in presence of alkali, serves as an excellent catalyst for the dehydrogenation of cyclohexane and methylcyclohexane, which lose all the six hydrogen atoms of the ring and yield hydrogen and benzene or toluene, with no trace of the tetrahydro- or dihydro-derivative of the aromatic hydrocarbon. This action commences at about 170° , and proceeds very rapidly at $200-300^\circ$.

At lower temperatures, the reverse change occurs, passage of hydrogen and benzene over the freshly-prepared palladium black heated at $100-110^\circ$ resulting in the hydrogenation of the benzene. Under these conditions, the temperature of equilibrium is about 210° , since, above this temperature, in spite of the presence of excess of hydrogen, dehydrogenation occurs.

The catalytic decomposition of cyclohexane hydrocarbons under the influence of palladium seems to be specific, as neither hexane, nor cyclopentane, nor methylcyclopentane undergoes similar dehydrogenation, at any rate below 300° . This reaction hence serves to distinguish between five- and six-carbon atom rings.

T. H. P.

Selective Catalysis: A New Tetrahydrobenzene [cyclohexene]. NICOLAI D. ZELINSKY (*J. Russ. Phys. Chem. Soc.*, 1911, 43, 1222-1224).—Dehydrogenation of cyclohexene (prepared by the action of oxalic acid on cyclohexanol) under the influence of palladium proceeds more energetically than that of cyclohexane (compare preceding abstract), the products being hydrogen and benzene. The cyclohexene employed in this experiment showed a continuous absorption spectrum, whilst another preparation, obtained by the action of quinoline on iodocyclohexane, was found to exhibit more or less marked selective absorption. The latter cyclohexene only underwent partial dehydrogenation in presence of palladium, the benzene formed being mixed with a new cyclohexene, C_6H_{10} , b. p. $77.5-78^\circ$ (corr.), d_4^{20} 0.8005, n_D^{20} 1.4416, the increment of the molecular refraction being 1.58; it has a fatty, aromatic odour, and is a saturated hydrocarbon, as it reacts with neither permanganate nor bromine.

T. H. P.

Isomerisation of Unsaturated Cyclic Hydrocarbons, C_6H_{10} . (Mlle.) V. I. Egorova (*J. Russ. Phys. Chem. Soc.*, 1911, 43, 116—1174).—**cycloHexylacetylene**, $C_6H_{11} \cdot C \equiv CH$, best prepared by the method of Darzens and Rost (*Abstr.*, 1909, i, 899), has D_4^0 0.8602, n_D^{20} 0.8424, n_D^{25} 1.4597.

cycloHexylidene-ethylene, $CH_2 \cdot C : C_6H_{10}$, obtained on heating cyclohexylacetylene with alcoholic potassium hydroxide for ten hours at 40° , is a liquid, b. p. $138-141^\circ$, D_4^0 0.8682, D_4^{20} 0.8508, n_D^{20} 1.4826, and, when heated with sodium in a sealed tube, gives the sodium derivative of cyclohexylacetylene (Darzens and Rost, *loc. cit.*).

1-Vinyl- Δ^1 -cyclohexene, $CH_2 \cdot CH \cdot C \begin{smallmatrix} \text{CH}_2 \cdot CH_2 \\ \text{CH} \cdot CH_2 \end{smallmatrix} > CH_2$, prepared by heating cyclohexylidene-ethylene with benzoic acid in a sealed tube for ten hours at 170° , is a liquid, b. p. $143-145^\circ$, D_4^0 0.8862, D_4^{20} 0.8701, n_D^{20} 1.49060, and, although it contains a conjugated linking, shows no optical exaltation (compare Auwers and Eisenlohr, *Abstr.*, 1910, ii, 25); it does not react with sodium. T. H. P.

Polymerisation of Diethylene Hydrocarbons. III. Divinyl. (Mlle.) V. LEBEDEV and (Mlle.) N. A. SKAVRONSKAJA (*J. Russ. Phys. Chem. Soc.*, 1911, 43, 1124—1131).—This paper is largely a repetition of one already published (this vol., i, 26).

4-Ethenylcyclo- Δ^1 -hexene (*loc. cit.*) gives with bromine 1- $\alpha\beta$ -dimethyl-3 : 4-dibromocyclohexane,

b. p. $69.5-70.5^\circ$. When oxidised with permanganate it yields β -carboxyadipic acid (butane- $\alpha\beta\delta$ -tricarboxylic acid), m. p. $111-113^\circ$ (compare Guthzeit and Engelmann, *Abstr.*, 1902, i, 742; Leuchs and Moos, *Abstr.*, 1909, i, 361).

The polymeride obtained, together with the above dimeride, on heating divinyl, yields an ozonide (*loc. cit.*) identical with that given by dicyclooctadiene (compare Harries, *Abstr.*, 1908, i, 254). The conclusion is hence drawn that the polymeride has the structure $(\begin{smallmatrix} \text{CH}_2 \cdot \text{CH} \cdot \text{CH} \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH} \cdot \text{CH} \cdot \text{CH}_2 \end{smallmatrix})_x$, and is de-polymerised by the action of ozone.

T. H. P.

Benzene Problem. ERNST MOHR (*Ber.*, 1911, 44, 2971).—Pauly has recently suggested (this vol., i, 986) that the existence of the aromatic hydrocarbon, C_6H_6 , decides for the centric formula for benzene in place of the Kekulé formula. It is doubtful, however, whether this criterion can be accepted, since the hydrocarbon, C_6H_6 , does not conform with the law of even numbers of atoms, and is therefore analogous to triphenylmethyl and the radicle of diphenyl nitrogen, NPh_3 , rather than with benzene, naphthalene, and anthracene.

T. A. H.

A New Hypothesis on Benzene. ANIBAL CHACÓN (Pamphlet, pp. 43).—See this vol., ii, 1080.

[Orientation in the Benzene Nucleus.] JULIUS OBERMAYER (*Ber.*, 1911, 44, 3179—3180).—A renewed claim for priority over Holleman (compare Abstr., 1910, i, 826; also Holleman and Caland, this vol., i, 849).
E. F. A.

Oxidation of Amino-acids by Alloxan, Isatin, and *p*-Benzoquinone. WILHELM TRAUBE (*Ber.*, 1911, 44, 3145—3148).—It was first shown by Strecker that alloxan oxidises aliphatic α -amino-acids to the aldehyde of the next lower carbon series with liberation of carbon dioxide and ammonia. Hurtley and Wootton (*Trans.*, 1911, 99, 288) have shown that dimethylalloxan behaves similarly. It is now found that alloxan likewise oxidises anilinoacetic acid to benzaldehyde and carbon dioxide, the solution becoming red. The amount of benzaldehyde produced was determined quantitatively by means of the phenylhydrazone.

Besides alloxan, isatin, *p*-benzoquinone and toluquinone are known to oxidise the amino-acid to aldehyde, whereas naphthaquinone and anthraquinone, parabanic acid, and chloroanil are without action. Fatty aromatic amines, for example, benzylamine, are in like manner oxidised to aldehydes by alloxan and isatin, but *p*-benzoquinone is without effect. Purely fatty amines, for example, isomylamine, are not oxidised by alloxan.
E. F. A.

Acenaphthene. II. FRANZ SACHS and GERHARDT MOSERER (*Ber.*, 1911, 44, 2852—2862. Compare Abstr., 1910, i, 726).—The importance recently acquired by acenaphthene for technical purposes renders desirable an extension of the accurate knowledge of its substitution products. 4-Acetylaminobenzenaphthene in glacial acetic acid at 0° is converted by concentrated nitric acid into 2-nitro-3-acetylaminobenzenaphthene, $\text{NHAc} \cdot \text{C}_{12}\text{H}_8 \cdot \text{NO}_2$, m. p. 253°, yellow needles, in which the ortho-relation of the substituents is proved by the fact that the compound in aqueous alcohol is reduced by sodium hyposulphite to the iminoazole, $\text{C}_{12}\text{H}_8 \langle \text{N} \rangle \text{CMe}$ (nitrate, $\text{C}_{14}\text{H}_{12}\text{N}_2 \cdot \text{HNO}_3$, m. p. 320°; platinichloride, $2\text{C}_{14}\text{H}_{12}\text{N}_2 \cdot \text{H}_2\text{PtCl}_6$; chloride, $\text{C}_{14}\text{H}_{12}\text{N}_2 \cdot \text{HCl}$), and also by the fact that the 2-nitro-3-aminobenzenaphthene, m. p. 222—224°, red prisms, obtained by its hydrolysis by alcohol and concentrated hydrochloric acid, is reduced by stannous chloride and hydrochloric acid to 2:3-acenaphthylenediamine, m. p. 140—142°, almost colourless needles, which condenses with phenanthraquinone and with diacetyl to form the azines, $\text{C}_{12}\text{H}_8 \langle \text{N} \rangle \text{C}_4\text{H}_8$, m. p. 243°, yellow needles, and $\text{C}_{12}\text{H}_8 \langle \text{N} \rangle \text{CMe}$, m. p. 200°, respectively.

2-Nitro-3-acetylaminobenzenaphthene is converted by boiling alcoholic sodium hydroxide into the sodium salt of 2-nitro-3-hydroxyacenaphthene, $\text{ONa} \cdot \text{C}_{12}\text{H}_8 \cdot \text{NO}_2 \cdot \text{H}_2\text{O}$, dark red crystals. 2-Nitro-3-hydroxyacenaphthene itself has m. p. 148°, crystallises in yellowish red needles, and is reduced by sodium hyposulphite in aqueous alcohol to 2-amino-3-hydroxyacenaphthene, m. p. 159°.

Quincke's 3:4-dinitroacenaphthene is obtained best by heating

finely-divided suspension of acenaphthene in glacial acetic acid with concentrated nitric acid at 80° for twenty minutes. Its reduction to 3:4-acenaphthylenediamine is conveniently effected by an excess of stannous chloride and hydrochloric acid. The *peri*-position of the two amino-groups is proved by the preparation of the following substances.

Phthalacaperinone (formula I), m. p. 290°, red needles, from the diamine and phthalic anhydride at about 200°; *acaperimidine* (formula II), m. p. 285°, greenish-brown crystals, from the diamine and formic acid in boiling alcohol; *acenaphthylene-3:4-thiocarbamide*, $C_{12}H_8 \begin{smallmatrix} \text{NN} \\ \text{NH} \end{smallmatrix} > \text{CS}$, colourless crystals, from the diamine and carbon disulphide in alcohol.

C. S.

Cholesterol. XIII. Cholesterylamine. ADOLF WINDAUS and J. ADAMLA (*Ber.*, 1911, 44, 3051—3058).—In their attempts to prepare cholesterylamine, the authors obtained *cholesterylurethane*, $C_{27}H_{47}O \cdot \text{CO} \cdot \text{NH}_2$, m. p. 212—213°, by heating cholesterol and carbamide at 220°. *Cholesterylamine*, $C_{27}H_{47} \cdot \text{NH}_2$, m. p. 98°, is obtained by heating cholesteryl chloride and alcoholic ammonia at 180° in the presence of a little ammonium iodide. The *hydrochloride*, *sulphate*, *platinichloride*, and *picrate*, m. p. 274—275° (decomp.), are described. The *acetyl* and the *benzoyl* derivatives have m. p. 243—244° and 236° respectively. The reduction of cholestenoneoxime by sodium and boiling alcohol yields a mixture of stereoisomeric bases (*picrate*, decomp. 253°; *platinichloride*, decomp. 252°; *benzoyl* derivative, m. p. 203°). The acetylated mixture has been separated by fractionation into three individual substances; one, identical with the preceding *acetyl* derivative, has m. p. 243—244°, another, β -*acetylcholesterylamine*, has m. p. 216—217°, and constitutes the chief ingredient of the acetylated mixture, whilst the third, γ -*acetylcholesterylamine*, has m. p. 190°.

Synthesis of Aromatic and Hydroaromatic Alcohols Containing the Allyl Group. IPPOLYT MATSCHUREVITSCH (*J. Russ. Phys. Chem. Soc.*, 1911, 43, 973—990).—The author has prepared a number of tertiary alcohols by the interaction of allyl bromide (or iodide), magnesium, and a carbonyl compound in ethereal solution (compare Javorsky, *Abstr.*, 1908, i, 753).

o-4-Xylylmethylallylcarbinol, $C_{15}H_{19}Me_2 \cdot \text{CMe}(\text{OH}) \cdot \text{CH}_2 \cdot \text{CH} \cdot \text{CH}_2$, prepared from *o*-4-xylyl methyl ketone, allyl bromide, and magnesium, is a colourless, viscous liquid with an aromatic odour, b. p. 141—144.5/19.5 mm., D_4^{20} 0.97258, n_D^{20} 1.52752.

m-4-Xylylmethylallylcarbinol, prepared from *m*-4-xylyl methyl ketone, is a pleasant-smelling, colourless, viscous liquid, b. p. 135—139.5/14.5 mm., D_4^{20} 0.97675, n_D^{20} 1.52882.

p-2-Xylylmethylallylcarbinol, prepared from *p*-2-xylyl methyl

ketone, is a liquid, b. p. 138—139°/22.5 mm., D_4^{20} 0.9774, n_D^{20} 1.52925.

1-Allylcyclohexene-1-ol, $\text{OH}\cdot\text{C}_6\text{H}_{10}\cdot\text{CH}_2\cdot\text{CH}:\text{CH}_2$, prepared from cyclohexanone, is a liquid, b. p. 95—97°/27.5 mm., D_4^{20} 0.9346, n_D^{20} 1.47564.

1-Methyl-3-allyl- Δ^1 -cyclohexene-3-ol,

prepared from 1-methyl- Δ^1 -cyclohexene-3-one, is a liquid, b. p. 99.5—100°/16.5 mm., D_4^{20} 0.95310, n_D^{20} 1.49923.

1:3-Dimethyl-5-allyl- Δ^5 -cyclohexene-5-ol,

prepared from 1:3-dimethyl- Δ^5 -cyclohexene-5-one, forms a colourless crystalline, fatty mass, m. p. 28—31°, b. p. 108—108.5°/17.5 mm.

1-Methyl-5-ethyl-3-allyl- Δ^1 -cyclohexene-3-ol,

has b. p. 120—122°/13.5 mm., D_4^{20} 0.91795, n_D^{20} 1.48731.

1-Methyl-5-propyl- Δ^1 -cyclohexene-3-one, $\text{CHPr}\left\langle\begin{array}{c}\text{CH}_2\cdot\text{CO} \\ \text{CH}_2\cdot\text{CMe}\end{array}\right\rangle\text{CH}_2$

obtained by condensing ethyl acetoacetate and *n*-butaldehyde in presence of diethylamine to ethyl α -diacetyl- β -propylglutarate, $\text{CO}_2\text{Et}\cdot\text{CHAc}\cdot\text{CHPr}\cdot\text{CHAc}\cdot\text{CO}_2\text{Et}$, and treating the latter with alkali, is a colourless liquid, b. p. 242—244°, 128—129°/37 mm., D_4^{20} 0.9267.

1-Methyl-5-propyl-3-allyl- Δ^1 -cyclohexene-3-ol,

prepared from the preceding compound, is a crystalline, waxy mass, m. p. 34—37°, b. p. 135—136°/29 mm., D_4^{20} 0.9225.

1-Methyl-5-isopropyl-3-allyl- Δ^1 -cyclohexene-3-ol, $\text{C}_3\text{H}_7\text{O}$, forms a waxy mass, m. p. 26—29°, b. p. 127—128°/25.5 mm., D_4^{20} 0.9175, n_D^{20} 1.48905.

1-Methyl-5-isobutyl-3-allyl- Δ^1 -cyclohexene-3-ol, $\text{C}_4\text{H}_8\text{O}$, prepared from the corresponding hexenone, was obtained as a crystalline, waxy mass, m. p. 50—52.5°, b. p. 140—142°/38 mm. T. H. P.

Bromination of Phenol. J. G. DINWIDDIE and JOSEPH H. KASTLE (*Amer. Chem. J.*, 1911, 46, 502—503).—It is well known that when bromine is added to an aqueous solution of phenol, tribromophenol and tribromophenol bromide are the only compounds produced. It is now shown that if bromine is added to solutions of phenol in glacial acetic acid, chloroform, carbon tetrachloride, or carbon disulphide, substitution takes place with the formation of a dibromophenol, probably the 2:4-derivative.

It is suggested that the peculiar behaviour of phenol in aqueous solution is due to its tendency to form quinonoid derivatives.

Tribromophenol bromide, $\text{CO}\left\langle\begin{array}{c}\text{CBr}\cdot\text{CH} \\ \text{CBr}\cdot\text{CH}\end{array}\right\rangle\text{CBr}_2$, is first produced, and reacts with phenol to form 2:4:6-tribromophenol. The mechanism of these reactions is discussed. E. G.

Isomerism and Polymorphism. II. EINAR BILLMANN (*Ber. 1911, 44, 3153—3157*).—Polemical (compare Hantzsch, *Abstr.*, 1910, 474; this vol., i, 715; Billmann, this vol., i, 367). Hantzsch's contention as to the persistence of the individuality of the mesochronoisomerides is based on what is probably only a retention of the inoculation nuclei.

Polymorphism is a very general property. Methylcoumarinic acid has been obtained in a new modification, m. p. 86°, in addition to that, m. p. 91—92°. E. F. A.

The Reactivity of Benzene Substituents and the Acidity of Aromatic Acids in their Dependence on Orientating Influences. The Structure of Benzene. JULIUS OBERMILLER (*J. pr. Chem.*, 1911, [ii], 84, 449—459). The author finds that the removal of the sulphonyl group from *o*-phenolsulphonic acid by heating with hydrochloric acid at 100°, takes place more readily than with the *para* compound, whilst the *meta*-acid, when subjected to the same treatment, remains intact.

The mobility of the sulphonyl group thus increases as the latter approaches the hydroxyl group, as represented in Claus's diagonal formula for benzene. The view is expressed that the increase in the reactivity of the hydrogen atoms of a side-chain is coincident with an increase in its acid character. The acidity of the side-chain should accordingly be greater the less firmly it is attached, and with position-isomeric compounds increase in the order *meta*, *para*, *ortho*. This is confirmed by the behaviour of the sulphanilic acids and, to some extent, by the phenolsulphonic acids.

It is shown that the acidity of the hydroxyl group of the isomeric phenolsulphonic acids, as judged by the ease with which the dimagnesium salts are hydrolysed, diminishes in the order *ortho*, *para*, *meta*, whereas from measurements of the hydrogen ion concentration of the sodium salts the order of acidity is *meta*, *para*, *ortho*. This discrepancy is referred by the author to differences in the condition of the benzene ring. F. B.

Reactivity of Aromatic Bromo-compounds. II. Formation of Aromatic Disulphides of the Types R·S·R'·S·R and R·S·R'·S·R'. ÉDOUARD BOURGOIS and A. FOUASSIN (*Bull. Soc. chim.*, 1911, [iv], 9, 938—944. Compare *Abstr.*, 1896, i, 17).—When *p*-dibromobenzene reacts with lead derivatives of the thiophenols, the two reactions represented by the following equations occur: (1) $2C_6H_4Br_2 + PbS_2R_2 = PbBr_2 + 2Br·C_6H_4·SR$, (2) $2Br·C_6H_4·SR + PbS_2R_2 = PbBr_2 + 2RS·C_6H_4·SR$. The first of these reactions takes place more rapidly than the second, and even if dibromobenzene is employed in large excess, some disulphide is always formed. The velocity of the second reaction increases with greater complexity of the thiophenol employed. Reaction begins at 180—185°, but only becomes practicable at 200°. Above 225° secondary actions occur. The two substances were heated together in an autoclave at 225°, and the resulting products extracted with ether or carbon disulphide and,

after removal of the solvent, fractionally distilled to separate the bromosulphide from the disulphide.

p-Bromodiphenyl sulphide (*loc. cit.*) reacts with the lead derivative of thiophenol to form *diphenyl p*-phenylene disulphide, C_6H_5SPb , m. p. 81.5° , b. p. $265^\circ/14$ mm., which crystallises in colourless spangles from hot alcohol.

p-Bromophenyl *p*-tolyl sulphide, $C_6H_4Br \cdot S \cdot C_6H_4Me$, m. p. 82.5° , b. p. $200.5^\circ/14$ mm., crystallises in pearly leaflets. *Di-p*-tolyl *p*-phenylene disulphide, $C_6H_4Me \cdot S \cdot C_6H_4 \cdot S \cdot C_6H_4Me$, m. p. 99° , b. p. $285^\circ/14$ mm., crystallises in prismatic needles.

p-Bromophenyl α -naphthyl sulphide, m. p. 73° , b. p. 247° , forms large, prismatic needles. *Di- α -naphthyl p*-phenylene disulphide, m. p. 148.5° , b. p. above $360^\circ/14$ mm. (decomp.), forms colourless rhombic tablets.

p-Bromophenyl β -naphthyl sulphide, m. p. 114.5° , b. p. $253^\circ/14$ mm., forms rhombic crystals. *Di- β -naphthyl p*-phenylene disulphide, m. p. 185° , b. p. above $360^\circ/14$ mm. (decomp.), is nearly insoluble in neutral solvents.

Phenyl p-tolyl *p*-phenylene disulphide, m. p. 55.5° , b. p. $272^\circ/14$ mm., obtained by heating *p*-bromodiphenyl sulphide with the lead derivative of tolyl mercaptan, is colourless and crystalline. T. A. H.

Reactivity of Aromatic Bromo-compounds. III. Action of Bromonitrobenzenes on Phenylmercaptides. HENRI BOUANGEAIS and P. HUBER (*Bull. Soc. chim.*, 1911, [iv], 9, 944—947).—It is known that *o*- and *p*-bromonitrobenzenes are more highly reactive than their meta-isomeride, and in confirmation of this, it is found that the two former, although they do not react with the lead derivative of thiophenol, give with the sodium derivative the corresponding nitrodiphenyl sulphides; with *m*-bromonitrobenzene, on the other hand, the nitro-group appears to undergo reduction with the formation of a red substance, m. p. 125.5° , which may be Gabriel's *m*-dibromoozobenzene (*this Journ.*, 1877, i, 307).

4-Nitrodiphenyl sulphide, m. p. 54.4° , b. p. $240^\circ/25$ mm., or $262.5^\circ/50$ mm., or $288.2^\circ/100$ mm., forms pale yellow, prismatic needles or hexagonal tablets (Kehrmann and Bauer, *Abstr.*, 1897, i, 27), and on oxidation gives 4-nitrodiphenylsulphone (Ullmann and Psdermadjian, *Abstr.*, 1901, i, 383).

2-Nitrodiphenyl sulphide, m. p. 80.2° , forms pale orange-coloured crystals from alcohol mixed with ether. On oxidation it furnishes 2-nitrodiphenylsulphone (*loc. cit.*), which is colourless, but becomes brown on exposure to light. T. A. H.

The Two Forms of Decahydro- β -naphthol (a Particular Case in Stereochemistry). LUIGI MASCARELLI (*Atti R. Acad. Lincei*, 1911, [v], 20, ii, 223—227).—Leroux (*Abstr.*, 1905, i, 279) described decahydro- β -naphthol as having m. p. 75° , b. p. 225° . Ipatieff gave m. p. 99 — 100° , b. p. 242 — 244° . By recrystallisation of a product obtained by the latter, the author has isolated two substances, A and B, which have the same composition and molecular weight, and are both stable towards permanganate. *a*-Decahydro-

naphthal forms flat, transparent crystals, m. p. 75°; b-decahydro-naphthal forms colourless, prismatic crystals, m. p. 103°, and is generally less soluble than its isomeride. From the consideration of the stereochemistry of monosubstituted decahydronaphthalenes it appears that four different decahydro-β-naphthols may exist, forming two pairs of enantiomorphs, and the two products above described are to be regarded as the two corresponding racemic mixtures. The stereoisomerism is due to the different positions which may be occupied by the hydrogen atoms attached to the carbon atoms 9 and 10. These two carbon atoms, although asymmetric, must necessarily have opposite configurations, and therefore the possible stereoisomerides are those due to the carbon atom to which the substituent is attached, regard being had to the different situations of the two hydrogen atoms attached to the carbon atoms 9 and 10 with which a given configuration of it can be associated.

R. V. S.

Constitution of Weselsky and Benedikt's Dinitroquinol methyl Ether. Preparation of Some Methyl Derivatives of the Dinitro-p-anisidines. FRÉDÉRIC REVERDIN and ARMAND DE LUC (*Arch. Sci. Phys. Nat.*, 1911, [iv], 32, 343—346; *Bull. Soc. chim.*, [11, [iv], 9, 925—928; *J. pr. Chem.*, 1911, [iii], 84, 554—558. Compare *Abstr.*, 1881, 1139; this vol., i, 123).—The authors have determined the constitution (I) for Weselsky and Benedikt's dinitroquinol methyl ether, and (II) for a nitroamine previously described by them (this vol., i, 123) with m. p. 125°.

starting with 2:6-dinitro-p-anisidine, by the action of methyl sulphate at 100°, 2:6-dinitrodimethyl-p-anisidine, m. p. 150°, was obtained. This substance with hot nitric acid yields a nitroamine, m. p. 139—140°, different from their original one; thus their nitroamine, m. p. 125°, is that of 3:5-dinitromethyl-p-anisidine (II), and since by boiling with sodium hydroxide solution it yields Weselsky and Benedikt's ether, the latter must have the constitution (I).

The authors were unsuccessful in attempts to methylate 3:5-dinitro-p-anisidine, but succeeded in methylating the corresponding 2:3- and 2:5-compounds, which, however, unlike the 2:6-compound, only yielded monomethyl derivatives.

2:3-Dinitromethyl-p-anisidine crystallises in deep red needles, m. p. 156°.

2:5-Dinitromethyl-p-anisidine crystallises in dull red, felted needles, m. p. 201—202°.

W. G.

Some Derivatives of Hydroxyquinol. VI. GUIDO BARGELLINI and ERMANNO MARTEGIANI (*Atti R. Accad. Lincei*, 1911, [v], 20, 183—190. Compare this vol., i, 305).—The present paper deals with the products of the condensation of benzoyl chloride, anisyl chloride, and phenylacetyl chloride, respectively, with hydroxyquinol trimethyl ether in the presence of aluminium chloride.

Benzoyl chloride and hydroxyquinol trimethyl ether yield a mixture of 2:4:5-trimethoxybenzophenone and 2-hydroxy-4:5-dimethoxybenzophenone. 2:4:5-Trimethoxybenzophenone, $C_{16}H_{14}O_5$, forms pale yellow needles, m. p. 97° . Its phenylhydrazone, $C_{21}H_{18}O_5N_2$, crystallises in colourless scales, m. p. $178-179^\circ$, and gives a yellowish-green coloration with concentrated sulphuric acid. 2-Hydroxy-4:5-dimethoxybenzophenone, $C_{15}H_{14}O_5$, forms yellowish-green, flat, prismatic crystals, m. p. $106-107^\circ$. Its alcoholic solution gives a yellowish-green coloration with ferric chloride. On methylation, it yields the above trimethyl ether. The acetyl derivative, $C_{17}H_{16}O_6$, crystallises as slightly yellow needles, m. p. $108-110^\circ$, and dissolves in concentrated sulphuric acid, giving an orange-yellow coloration. When treated with hydrobromic acid in glacial acetic acid (compare Starmann, Abstr., 1908, i, 190), both the trimethoxy- and the dimethoxy derivatives yield 2:4-dihydroxy-5-methoxybenzophenone, $C_{14}H_{10}O_5$, which forms small, yellow needles, m. p. $183-185^\circ$, and in alcoholic solution gives a yellowish-green coloration with ferric chloride. All three methoxybenzophenones dissolve in concentrated sulphuric acid with production of an orange-yellow coloration. The positions of the methoxy- and hydroxy-groups are assigned on the basis of analogies and regularities to be found in the literature, and the constitutions of the following substances are arrived at in a similar manner.

Anisyl chloride and hydroxyquinol trimethyl ether give a mixture of 2:4:5:4'-tetramethoxybenzophenone and 2-hydroxy-4:5:4'-trimethoxybenzophenone. 2:4:5:4'-Tetramethoxybenzophenone,

is a yellowish-white, crystalline powder, m. p. $122-124^\circ$, and gives an orange-yellow coloration with sulphuric acid. Its phenylhydrazone, $C_{22}H_{18}O_6N_2$, has m. p. $173-174^\circ$, and dissolves in concentrated sulphuric acid, with production of a green coloration. 2-Hydroxy-4:5:4'-trimethoxybenzophenone, $C_{16}H_{14}O_6$, crystallises in small, yellow needles, m. p. $127-128^\circ$, and dissolves in concentrated sulphuric acid, producing an orange coloration. The alcoholic solution gives a yellowish-green coloration with ferric chloride.

The products of the reaction between phenylacetyl chloride and hydroxyquinol trimethyl ether are 2:4:5-trimethoxy- and 2-hydroxy-4:5-dimethoxy-deoxybenzoin. 2:4:5-Trimethoxydeoxybenzoin,

crystallises in colourless leaves, m. p. $76-77^\circ$, and gives an orange coloration when dissolved in concentrated sulphuric acid. Its phenylhydrazone, $C_{22}H_{18}O_4N_2$, is a yellow, crystalline powder, m. p. $142-143^\circ$; it gives a yellowish-green coloration with concentrated sulphuric acid. 2-Hydroxy-4:5-dimethoxydeoxybenzoin, $C_{16}H_{14}O_4$, forms colourless leaves, m. p. 94° ; it dissolves in concentrated sulphuric acid with production of a yellowish-green coloration, and its alcoholic solution gives a green coloration with ferric chloride. R. V. S.

Benzyl Orthothioformate. JOHN A. SMYTH (Proc. Univ. Durham Phil. Soc., 1911, 4, 75-83. Compare Dennstedt, Abstr., 1879, 318, 1880, 646).—A white, crystalline solid, m. p. 103° , produced in small quantities when hydrogen chloride acts on benzyl mercaptan in the

presence of glacial acetic acid, is proved to be identical with Dennstedt's methyl orthothioformate. Its formation is due to the presence of formic acid as an impurity in the acetic acid employed; the yield is equivalent to the amount of formic acid present. This indicates a ready method of preparing the thio-ester by the action of hydrogen chloride on an solution of benzyl mercaptan (1 mol.) dissolved in glacial acetic acid containing sodium formate (3 mols.). The reaction under these conditions is reversible:

The thio-ester can be accurately estimated by means of standard dioxine solution under certain conditions. The reaction takes place in two stages; in the first, hydrochloric acid acts as a catalyst. The second stage, although reversible, proceeds almost completely, as the velocity of reaction is very great.
